Title: Evaluation of quality of life in patients with advanced and metastatic breast cancer proposed for palliative chemotherapy and best supportive care versus best supportive care

Anda-Natalia T Ciuhu¹, Gabriela I Rahnea Nita¹, Mihaela T Popescu² and Roxana Andreea D Rahnea Nita³. ¹Saint Luke Hospital, Bucharest, Romania; ²Colentina Clinical Hospital, Bucharest, Romania and ³Romanian Society of Palliatology and Thanatology, Bucharest, Romania.

Body: Background:
In Romania many patients neglect their symptoms and present to the doctor in advanced stages of cancer. In the case of patients with breast cancer who present with very advanced locoregional disease (ulcerated or hemorrhagic tumors) and symptomatic metastatic disease (visceral or skeletal pain, dyspnea), the choice between chemotherapy/hormonal therapy and best supportive care and only best supportive care became very difficult.

Objective:
Evaluation of quality of life in patients with advanced and metastatic breast cancer proposed for palliative chemotherapy and best supportive care versus best supportive care

Materials and methods:
In the last 6 month of the year 2013, 57 patients with advanced and metastatic breast cancer were randomized to either chemotherapy/hormonal therapy in addiction to best supportive care or to best supportive care. The patients were naive to chemotherapy, with performance status – ECOG between 2 and 3 and had symptomatic disease. The randomization of patients was made according to their choice. The performance status and the symptoms were evaluated at the baseline and, later, at each admission in the Oncology Palliative Care Department.

Results:
More patients in the chemotherapy group (92.68%, 38/41) had an improve quality of life compared to those in the best supportive care group (56.25 %, 9/16). The overall survival was longer in the chemotherapy group.

Conclusions:
The results show that chemotherapy/hormonal therapy improve the quality of life and overall survival in very advanced locoregional disease and symptomatic metastatic breast cancer. The number of patients who benefit from chemotherapy and best supportive care is higher versus patients who benefit only from best supportive care.

Key words: chemotherapy/hormonal therapy, best supportive care, breast cancer.

Title: Clinical outcome in breast cancer patients: What Epstein-Barr virus is doing?

Mohammed Habib¹, Gina Marrao², Dominique Bicout³, Artur Paiva², Carlos Freire de Oliveira⁴ and Emmanuel Drouet¹. ¹Université de Grenoble-Alpes, Unit for Virus Host-Cell Interactions, UMI 3265 UJF-CNRS-EMBL Grenoble1, Grenoble, Cedex 9, France; ²Coimbra University Hospital, Coimbra, Portugal; ³Team Environment and Health Prediction in Populations Unit – TIMC Laboratory, UMR CNRS 5525, Université Joseph Fourier, Grenoble1, Grenoble, Cedex 9, France; ⁴Coimbra University Hospital, Coimbra, Portugal; ⁵University Hospital, Coimbra, Portugal and ⁶Université de Grenoble-Alpes, Unit for Virus Host-Cell Interactions, UMI 3265 UJF-CNRS-EMBL Grenoble1, Grenoble, Cedex 9, France.

Body: In breast carcinomas (BC), the impact of Epstein-Barr Virus (EBV) infection on clinical outcomes has not been investigated yet. For nearly two decades, reports have suggested that Epstein–Barr virus (EBV), belonging to the gamma-herpes virus subfamily and infecting most people worldwide, may be a putative factor in the breast cancer natural history. In this paper, the overall survival of 85 patients with BC was assessed in a prospective study during an 87-month follow-up. The aim of our study was to evaluate the effect of EBV infection combined with the survival in all patients. We focused our study around three axis: i) The EBV DNA detection (measured by qPCR) both in breast cancer tissues and in peripheral blood mononuclear cells (PBMCs), ii) the IFN-γ and TNF-α intracellular immunostaining test combined with flow cytometry analysis iii) the clinical outcome of the patients and the pathological characteristics. These experiments were also completed by searching the EBV replicating form through the titration of serum anti-ZEBRA antibodies. No association could be found (i) between EBV detection in tumor/PBMCs and tumor histology and (ii) between EBV and other prognostic factors. The effect of the EBV load (PBMCs or/and tumor) on patients’ survival was analyzed by using both univariate and multivariate analysis combined with an analysis of covariance. The patients with anti-ZEBRA antibodies at high titers had a worse overall survival (p=0.002). According to the survival curves, patients who recovered from the disease had a measurable latent form of EBV DNA load, together with a high frequency of IFN-γ and TNF-α producing PBMCs (p=0.04), suggesting a type Th1- polarized immune response both in the tumor and in the periphery. These data point to a plausible beneficial role of EBV, which could occur through activation of nonspecific anti-tumoral immune responses. Our findings have revealed the following unexpected properties of this so-called “double faceted” EBV: (i) the latent form of this virus, measured and quantified by the tumor viral EBV DNA, confers a survival advantage to BC patients; (ii) there is an association between high anti-ZEBRA titers and poor outcome, though the high anti-ZEBRA response could be the result of late stage cancer and not the cause of poor outcome. Given that this study assessing the beneficial effects of the EBV was conducted over a long time period, these results are a relevant basis for future studies involving a larger patient population.
Title: Adenanthin, a new peroxiredoxin inhibitor, induces a switch between estrogen receptor alpha-mediated and Src/Akt-driven signaling in breast cancer cells

Malgorzata Bajor¹, Agata O Zych¹, Patrick C O'Leary²,³, Anna Czekalska¹, William M Gallagher³, Jakub Golab¹ and Radoslaw Zagozdzon¹. ¹Center of Biostructure Research, Medical University of Warsaw, Warsaw, Poland; ²Helen Diller Family Comprehensive Cancer Center, University of California, San Francisco, CA and ³Cancer Biology & Therapeutics Laboratory, UCD Conway Institute, UCD School of Biomolecular and BioMedical Science, Dublin, Ireland.

Body: Increasing evidence indicates that oxidative stress is involved in the progression of estrogen receptor (ER)-positive breast cancer. A moderate increase in cellular oxidants contributes to the genomic instability and to the change in cellular growth pattern, which in turn can facilitate progressive transformation of normal cells into cancer cells. Accordingly, the oxidative stress-related gene expression signature has been suggested to correlate with therapy resistance and poorer outcome in breast cancer. Therefore, it is crucial to determine the antioxidant defense mechanisms that are utilized by breast cancer cells to regulate oxidative stress.

Peroxiredoxin 1 (PRDX1) is one of the most prevalent hydrogen peroxide scavenging enzymes in mammalian cells. Our recent studies indicated that PRDX1 is an independent biomarker of favorable prognosis in ER-positive breast cancer. Our results indicate the mechanistic link between PRDX1 and ERα in breast cancer and suggest a role for PRDX1 in mammary carcinogenesis. We provide a molecular explanation for this phenomenon in the current project.

To evaluate the importance of PRDX1 activity in ER-positive breast cancer, we have used adenanthin, a newly described PRDX1/2 inhibitor. In our studies, we have shown that adenanthin strongly inhibits metabolism of exogenous hydrogen peroxide by breast cancer cells. This phenomenon is accompanied by a shift from H₂O₂-degrading PRDX1 dimers into enzymatically inactive monomers and by a dramatic decrease of ERα protein presence in the cells. Moreover, we have observed that incubation of ER-positive breast cancer cells with adenanthin leads to a marked increase in phosphorylation status of proteins associated with Src-Akt-driven signaling in breast cancer. Thus, our results suggest that PRDX1 can play an important role in controlling the switch between estrogen receptor- and growth factor-driven signaling in breast cancer.

In summary, in our studies we describe for the first time molecular consequences of rapid dysfunction of PRDX-related system in ER-positive breast cancer. The deeper knowledge on the mechanisms of PRDX1 functioning can change our understanding of the events leading to the progression of ER-positive breast cancer and provide new opportunities for pharmacological interventions in this disease, especially in the context of recent observations connecting the oxidative stress and resistance to endocrine therapy.
Title: CD59 expression is associated with MDA-MB-231-HM cells' metastasis and prognosis of breast cancer patients

qianwen Ouyang1,2,3,6, long Zhang4,6, peipei Ding4,5, weiguo Hu4,5, rongchen Luo1,2 and zhiming Shao3. 1Cancer Center, Guangzhou, China; 2Traditional Chinese Medicine-Integrated Hospital, Southern Medical University, Guangzhou, China; 3Breast Cancer Institute, Cancer Hospital/Cancer Institute, Shanghai Medical College, Institutes of BioMedical Sciences, Fudan University, Shanghai, China; 4Cancer Institute, Collaborative Innovation Center of Cancer Medicine, Fudan University Shanghai Cancer Center, Shanghai Medical College, Fudan University, Shanghai, China; 5Institutes of BioMedical Sciences, Fudan University, Shanghai, China and 6The Third Hospital of Nanchang, Nanchang, China.

Body: Breast cancer is the most frequent cancer among women so far and its metastasis remains predominant clinical challenge. CD59 is a membrane complement regulatory protein (mCRP), and is overexpressed in many types of solid tumors. It's been hypothesized that CD59 overexpression may facilitate tumor metastasis. To reveal the relationship between CD59 expression and metastasis of breast cancer, we transfected recombinant retrovirus encoding CD59 and shRNA targeting human CD59 into MDA-MB-231 and MDA-MB-231-HM cell lines respectively, followed by essential detection. CCK8 analysis, in vivo metastasis model construction were carried out to examine cell growth and metastasis in vitro and in vivo in both transfected cell lines. The results demonstrated that CD59 expression levels were functionally changed. Surprisingly, cell growth rates of the cell lines were altered both in vitro and in vivo accordingly, which was accompanied by reduced metastasis in the lungs in the MDA-MB-231-HM cell line xenograft model when CD59 was knocked down. Clinical data show that breast cancer patients with high expression of CD59 is more likely to suffer metastasis, shorter disease-free and overall survival. We show that CD59 expression is associated with tumor cell metastasis and outcome of breast cancer patients.
Title: Provista-001 a multi-center prospective study of protein signature used in the differentiation of benign breast lesions from invasive breast cancer in women under the age of 50 with a BI-RADS 3 or 4

David E Reese¹, Michael Silver¹, Susan Yeh², Sherri Borman² and Henderson C Meredith². ¹Provista Diagnostics, New York, NY and ²Provista Diagnostics, Scottsdale, AZ.

Body: Background: Over-diagnosis of breast lesions represents a significant problem in detection and screening of breast cancer, especially in women under the age of 50. Despite this issue, few new approaches have been developed to augment standard of care in the more precise detection of breast cancer. The combination of breast imaging, which provides anatomical evidence, with a robust protein signature that would detect biochemical cues of breast cancer offers an attractive approach to this problem. We have recently identified a protein signature composed of immune-regulatory cytokines, growth factors and tumor derived autoantibodies. Here, we test the hypothesis that a protein signature, combined with standard of care can greatly increase the precision of breast cancer diagnosis in women under the age of 50 in a randomized and blinded study.

Methods: Provista-001 enrolled 351 patients from 10 sites across the US and will follow patients for 6 months following the first blood draw under IRB approval. Patients were consented after first assessment of a BIRADS 3 or 4 and considered eligible if they were under the age of 50, no history of cancer, no prior breast biopsy, and were assessed as BIRADS 3 or 4 within 21 days of blood draw. Upon enrollment, patients were randomized to either training or validation groups. Clinical truth was set at equal to or greater than 80% sensitivity/specificity. Serum protein biomarkers and autoantibodies identified in prior proteomic screens were measured in serum samples collected prior to biopsy. Individual biomarker (22 serum protein and autoantibodies) concentrations, together with specific patient data were evaluated using various logistic regression models developed from prior retrospective studies. A training set, comprised of 200 patients, was used to develop and refine new models, which were then validated in the remaining 151 subjects. Clinical findings were compared to biopsy (largely BIRADS 4) or will be followed for 6 months and re-assessed (BIRADS 3).

Results: The novel algorithm utilizing patient data, serum protein and autoantibody concentrations combined with regression models was able to distinguish benign from breast cancer lesions in a statistically significant manner. Importantly, the serum protein biomarkers alone were unable to adequately distinguish benign lesions, consistent with prior work. However, the addition of tumor autoantibodies markedly increased both the sensitivity and specificity of the assay in this group of women. The use of the algorithm in conjunction with imaging was more accurate than imaging alone in this population.

Conclusions: Our current findings suggest that when used in combination, the protein signature developed here and breast imaging provides a more precise detection methodology than either alone. This is particularly important in women under the age of 50 where a low prevalence of disease makes detection difficult. The follow-up data at six months (BIRADS 3) will yield additional data in this understudied group of women. Additional studies utilizing the protein signature with women over the age of 50 are currently underway.
**Title:** Teasing out the PALB2 phenotype

Emily K Dalton¹, Rachel McFarland¹, Holly Laduca¹, Shuwei Li¹ and Chia-Ling Gau¹. ¹Ambry Genetics, Aliso Viejo, CA.

**Body:**

**Background:** Biallelic mutations in PALB2 (Partner and Localizer of BRCA2) are known to cause Fanconi Anemia Type N. Multiple reports have demonstrated an increased risk for cancer in individuals heterozygous for PALB2 mutations. For example, a recent study by Antoniou et al reported a 33-58% lifetime risk for breast cancer in PALB2 mutation carriers, with 30% of carriers reporting triple negative breast cancer (TNBC). Other studies have suggested associations between PALB2 heterozygosity and pancreatic cancer, ovarian cancer, male breast cancer, and prostate cancer as well. We aimed to better define PALB2 phenotypes by assessing clinical history of TNBC, pancreatic, ovarian, and prostate cancers amongst PALB2 mutation carriers identified via multigene panel testing.

**Methods:** We reviewed clinical histories of 11,007 individuals who underwent PALB2 sequence and deletion/duplication analysis as part of a multigene hereditary cancer panel. Descriptive statistics were utilized for clinical histories of PALB2 carriers, and chi square analysis was used to compare clinical histories of PALB2 mutation carriers to mutation-negative controls. Individuals with mutations in other cancer susceptibility genes were excluded from analysis.

**Results:** A total of 98 PALB2 mutation carriers identified among 9610 individuals were included in our analysis. The majority of mutation carriers were Caucasian (80%) and female (92.8%). All identified mutations were truncating (nonsense, frameshift, or gross deletions). No pathogenic missense mutations were identified in this cohort. 77.6% (n=76) of mutation carriers had breast cancer, diagnosed at a mean age of 48. Hormone receptor status was available for 48 mutation carriers and 2469 controls. 37.5% (18/48) of breast cancers in mutation carriers were reported as triple negative, compared to 17.1% (423/2469) of breast cancers in controls (OR: 2.9; p=0.0002). 7.8% (n=8) of PALB2 mutation carriers had ovarian cancer. There was no significant difference in the incidence of ovarian cancer between PALB2 mutation carriers and controls (OR: 0.65; p=0.25). Additionally, mutation carriers were significantly less likely to have a family history of ovarian cancer than controls (OR: 0.5; p=0.02). 5.9% (n=6) of mutation carriers had pancreatic cancer, diagnosed at a mean age of 57.8, compared to 61 for controls. PALB2 mutation carriers were 1.3 times more likely to have personal and/or family history of pancreatic cancer, although this was not statistically significant (p=0.22). Similarly, PALB2 mutation carriers were 1.5 times more likely to have a family history of prostate cancer, although this was not statistically significant (p=0.09).

**Conclusions:** Our data supports existing literature associating PALB2 mutations with TNBC. We did not observe significant associations between PALB2 carrier status and a clinical history of pancreatic, prostate, or ovarian cancers. However, this data should be interpreted with caution, as it is possible that unidentified genetic factors contributed to the clinical history of cancer in our mutation-negative controls. Investigation of PALB2-associated cancer risks in an unselected prospective cohort would help to further elucidate the PALB2 phenotype.
Title: Ki-67 and p53 are useful factors to predict long term survival in low-risk luminal A breast cancer patients

Ha Woo Yi¹, Se Kyung Lee¹, Soo Youn Bae¹, Jun Ho Lee¹, Hyun-Chul Lee¹, Won Ho Kil¹, Jeong Eon Lee¹, Seok Won Kim¹ and Seok Jin Nam¹. ¹Samsung Medical Center, Seoul, Korea.

Body: Overexpression of p53 is the most frequent genetic alteration in breast cancer. Recently, many studies have shown that the expression of mutant p53 differs for each subtype of breast cancer and is associated with different prognoses. In this study, we aimed to determine the suitable cut-off value to predict the clinical outcome of p53 overexpression and its usefulness as a prognostic factor in each subtype of breast cancer, especially in luminal A breast cancer. Approval was granted by the Institutional Review Board of Samsung Medical Center. We analyzed a total of 7739 patients who were surgically treated for invasive breast cancer at Samsung Medical Center between Dec 1995 and Apr 2013. Luminal A subtype was defined as ER&PR + and HER2- and was further subclassified according to Ki-67 and p53 expression as follows: luminal A (Ki-67-, p53-), luminal A (Ki-67+, p53-), luminal A (Ki-67-, p53+), luminal A (Ki-67+, p53+). Low-risk luminal A subtype was defined as negative for both Ki-67 and p53 (luminal A (Ki-67-, p53-)) and others subtypes were considered to be high-risk luminal A breast cancer. A cut-off value of 10% for p53 was a good predictor of clinical outcome in all patients and luminal A breast cancer patients. The prognostic role of p53 overexpression for OS and DFS was only significant in luminal A subtype. The combination of p53 and Ki-67 has been shown to have the best predictive power as calculated by the area under curve (AUC), especially for long-term overall survival.

In this study, we have shown that overexpression of p53 and Ki-67 could be used to discriminate low-risk luminal A subtype in breast cancer. Therefore, using the combination of p53 and Ki-67 expression in discriminating low-risk luminal A breast cancer may improve the prognostic power and provide the greatest clinical utility.
**Title:** Characterization of the constitutive and tumor microenvironment-mediated changes in the expression, localization and function of CREB in HER-2/neu-induced tumor cells

Barbara Seliger¹, Andre Steven¹, Sandra Leisz¹, Bernhard Hiebl², Claudia Wickenhauser³, Chiara Massa¹, Manuela Iezzi⁴, Davide Bedognetti⁵, Francesco Marincola⁵ and Rolf Kiessling⁶. ¹Institute of Medical Immunology, Halle, Germany; ²Center for Basic Medical Research, Halle, Germany; ³Institute of Pathology, Halle, Germany; ⁴Center for Aging Sciences, Chieti, Italy; ⁵Sidra Medical Research Center, Doha, Qatar and ⁶Karolinska Institutet, CCK, Stockholm, Sweden.

**Body:** Despite the cAMP responsive element-binding protein (CREB) is involved in tumorigenicity, a link between HER-2/neu-induced transformation, CREB activation and alterations of the tumor micromilieu and cellular localization has not yet been established, which might contribute to the pathogenesis of HER-2/neu-associated tumors including mammary carcinoma. Using in vitro models of HER-2/neu-overexpressing and HER-2/neu-negative/silenced tumor cells as well as human mammary carcinoma lesions with defined HER-2/neu status a correlation of HER-2/neu overexpression with an increased expression and activation of CREB accompanied by an enhanced signal transduction and increased angiogenesis was detected both in vitro and in vivo. Hypoxia revealed a HER-2/neu-dependent CREB activation, which was associated with an upregulation of HIF-1α, GLUT1 and VEGF expression and altered microenvironment such as enhanced cell migration and matrix metalloproteinase-mediated invasion as well as increased extracellular lactate concentrations. The CREB-dependent hypoxic response was further accompanied by ubiquitination and mitochondrial colocalization of CREB and an altered mitochondrial gene expression. Furthermore, CREB downregulation in HER-2/neu-transformed cells by shRNA and by the treatment with the inhibitors KG-501 and lapatinib caused morphologic changes, a reduced cell proliferation and G0/G1 cell cycle arrest, which could be rescued by CREB expression. This was accompanied by a reduced cell migration, wound healing, an increased fibronectin adherence, invasion and matrix metalloproteinase expression. In vivo shCREB HER-2/neu+ cells, but not control cells exerted a significantly decreased tumorigenicity associated with a decreased proliferative activity, an enhanced apoptosis rate and an increased frequency of T lymphocytes in peripheral blood mononuclear cells. Thus, CREB seems to play an important role in the HER-2/neu-mediated transformation process of (mammary) tumor cells by altering their in vitro and in vivo growth characteristics as well as their immunogenicity.
Novel oncogene CNOT2 regulates proliferation and tumor angiogenesis targeting VEGF in MDA-MB-231 breast cancer cells

Sunghoon Kim1, Eunjung Sohn1 and Deokbeom Jung1. 1Kyung Hee University, Seoul, Korea; 2Kyung Hee University, Seoul, Korea and 3Kyung Hee University, Seoul, Korea.

Body: CCR-NOT (CNOT2) complex plays an important role in regulating the mRNA decay and translation repression. Here, we investigated the role of CNOT2 in human breast cancers. We found that CNOT2 was overexpressed in breast, pancreas, or prostate cancer cell lines and tissues. Proliferation of MDA-MB231 cells was suppressed by siRNA and shRNA mediated silencing of CNOT2. Knockdown of CNOT2 by siRNA transfection in MDA-MB-231 breast cancer cells decreased cell motility of MDA-MB231 cells, while overexpression of CNOT2 enhanced motility. Inhibition of CNOT2 significantly reduced clonogenicity, while overexpression of CNOT2 enhanced. Furthermore, silencing of CNOT2 attenuated cancer related genes such as cyclin D1, VEGF, or IκB as well as ERK, AKT in MDA-MB-231 breast cancer cells. Overall, our findings suggest that novel oncogene CNOT2 promotes tumor proliferation and motility via enhancement of survival genes and VEGF in MDA-MB-231 breast cancer cells.

Title: Mammaglobin is a potent regulator of breast cancer processes leading to disease progression

Roxann Guerrette¹, Nadia Picot¹ and Gilles Robichaud¹. ¹Université de Moncton, Moncton, NB, Canada.

Body: Metastasis is the major cause of death in women suffering from breast cancer. To provide a better understand breast cancer progression, we have studied the role of mammaglobine-1 (MGB1) gene in breast cancer pathogenesis. MGB1 has been extensively studied as a diagnostic biomarker due to its abundant expression in mammary cancer cells. Yet, MGB1’s role in disease progression is still unknown. Our experimental results demonstrate for the first time that MGB1 in a pivotal regulator on breast cancer malignancy. More precisely, loss of MGB1 expression correlates with a decrease in proliferation, spheroid formation, migration, and invasion capacities of breast cancer cells. Concomitantly, we also observe that MGB1 expression activates pro-malignant signaling cascades such as MAPKs, focal adhesion kinase (FAK) and NFkB pathways. Moreover, MGB1 promote epithelial to mesenchymal (EMT) features which coincide with our findings. Our study provides the first evidence for MGB1 as regulator of breast cancer malignancy and disease progression.
Title: Loss of long non-coding RNA LOC285194 is associated with poor prognosis in triple-negative breast cancer by activating microRNA-24/TGF-β signaling

Xiaojian Ni\(^1\) and Zhimin Shao\(^1\). \(^1\)Shanghai Cancer Center and Cancer Institute, Shanghai Medical College, Fudan University, Shanghai, China.

Body: Background: Triple-negative breast cancer (TNBC) is a highly aggressive tumor subtype associated with poor prognosis. The lack of obvious targets is a major challenge in treating patients with triple-negative breast cancer. Long non-coding RNAs are reported to be strongly correlated with poor patient prognosis, suggesting a potential role in cancer progression. Thus, identification of novel targets of long non-coding RNA is urgent for improving outcomes in triple-negative breast cancer.

Methods and Results: Here we conducted HTA 2.0 microassay analyses in 200 triple-negative breast cancer patients, which include normal tissues and primary tumors. We identified for the first time that LOC285194 was significantly down-regulated in primary tumors than normal tissues in triple-negative breast cancer. Multivariate analysis showed that loss expression of LOC285194 was an independent predictor for poor disease-specific survival (DFS) in triple-negative breast cancer. Through in vitro assays, we confirmed that silencing of LOC285194 expression by shRNA in MDA-MB-231 and MDA-MB-468 breast cancer cells, can potentiate the proclivity to metastasize in transwell assay and enhance tumorigenesis in vivo by injection into the right flank of the nude mice. In a reverse-complimentary approach, we determined that elevated LOC285194 expression in highly metastatic breast cancer cell lines (MDA-MB-231Bo) can suppress the ability of invasion and metastasis in vitro and in vivo. Mechanistically, microassay reveals that the metastatic behavior strongly correlates with increased microRNA-24 levels and overexpression of TGF-β type II receptor (TGF-βR2). Dual luciferase reporter assay confirmed that long non-coding RNA LOC285194 was an target of microRNA-24. Conversely, restoration of LOC285194 can inhibit the activation of this pathway in MDA-MB-231Bo cells.

Conclusion: By utilizing a series of mammary tumor cell lines and animal models, we demonstrate that long non-coding RNA LOC285194 acts as a tumor suppressor in triple-negative breast cancer through regulating microRNA-24/TGF-β signaling pathway which might be a potential prognostic indicator and therapeutic target for triple-negative breast cancer.

Title: Weight loss reversed the carcinogenic effect of obesity on basal-like breast cancer

Yuanyuan Qin¹, Sneha Sundaram¹, Liyang Zhao¹, Luma Essaid¹, Kirk K McNaughton³, Katharine M Bendt²,⁶, David B Darr²,⁶, Melissa A Troester²,⁷,⁸ and Liza Makowski¹,²,⁴,⁵. ¹Gillings School of Global Public Health and School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC; ²Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC; ³University of North Carolina, Chapel Hill, NC; ⁴UNC Nutrition Obesity Research Center, University of North Carolina, Chapel Hill, NC; ⁵University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁶Mouse Phase I Unit, Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁷University of North Carolina, Chapel Hill, NC and ⁸University of North Carolina at Chapel Hill, Chapel Hill, NC.

Body: Epidemiologic studies demonstrate that obesity is associated with a subtype of breast cancer called basal-like breast cancer (BBC), which is fast proliferating and aggressive, with no targeted therapies. Using the C3(1)-TAg murine model of BBC, we have previously shown that obese adult mice displayed significantly decreased tumor latency compared to lean mice with induction of the oncogenic HGF/c-Met pathway. Reducing adiposity is predicted to lower incidence of BBC in human population studies. Thus, the objective of this study was to investigate how a diet-switch to reduce obesity affected BBC onset and early progression. C3(1)-TAg mice were placed on a control low fat diet (LFD) and remained lean, high-fat diet (HFD) to induce obesity, and a group made obese by HFD that were then switched to LFD to induce weight loss. Just two weeks after weight loss, mice in the diet switch group had weights and adiposity similar to lean mice. Weight loss caused a 51.4% decrease in adiposity (P<0.0001) compared to obese mice. Importantly, mice that lost weight displayed significantly delayed tumor latency (17 week) compared to obese mice on HFD (15 week), with no differences detected in tumor burden or growth. Therefore the obese microenvironment that promotes early tumor onset can be reprogrammed with weight loss and restoration of a lean phenotype. Ongoing studies are examining HGF/cMet expression by immunohistochemistry in normal mammary glands and tumors to determine the contribution of this obesity-responsive pathway. Metabolomics and RNAseq analysis will identify novel obesity-dependent pathways relevant to BBC. In conclusion, we demonstrated that loss of adiposity protected against early BBC onset. Further research will identify important biomarkers associated with obesity and weight loss that can be compared through conserved biology approaches.
Title: Circulating methylated DNA of pregnancy-associated plasma protein A as a clinically useful biomarker in breast cancer

Richard Sainsbury¹, Karsten Koehler², Catherine Page² and Saroj Velamakanni². ¹UCL, London, United Kingdom and ²Fahy Gurteen Labs, Cambridge, United Kingdom.

Body: Background: A recent report suggests that Pregnancy-Associated Plasma Protein A (PAPPA) plays a pivotal role in normal cell division and is targeted early in breast cancer development. Epigenetic silencing of PAPPA is highly prevalent in precursor lesions and invasive breast cancer, correlating with loss of PAPPA protein expression. In normal breast tissue PAPPA promoter methylation was not observed (Journal of Pathology 344-356: 2014). We sought to test the hypothesis that PAPPA promoter hypermethylation can be detected in cell-free tumour specific DNA (ctDNA) in the bloodstream of patients with metastatic breast cancer.

Methods: Plasma derived from 12 patients with metastatic breast cancer was examined for ctDNA. A semi-quantitative real-time PCR based MethyLight assay was used for detection of PAPPA methylation. Spiking experiments with breast cancer cell lines were performed to develop the assay and confirm linearity of sodium bisulfite treatment.

Results: Percentage methylated reference (PMR) values from spiking experiments with PAPPA methylated and non-methylated DNA in plasma (matrix) demonstrate good linearity for the PAPPA gene and the endogenous control Col2A. PAPPA methylation was detected in 10 out of 12 (83%) of the metastatic breast cancer samples. In stark contrast, epigenetic silencing of PAPPA was not detected in any of the plasma samples from non-cancer bearing patients (n=10).

Conclusions: Given the potential clinical impact of our data, this study is being extended to include early stage breast cancer patients with poor prognostic clinic-pathological indicators. Our proof-of-concept findings indicate that testing for PAPPA promoter methylation in ctDNA may be used as a biomarker of disseminated disease, helping clinicians with treatment decisions and adjusting those choices as conditions change. By developing and refining more sensitive techniques, PAPPA methylation testing in ctDNA could also find practical utility in breast cancer screening.
Title: S0800: Nab-paclitaxel, doxorubicin, cyclophosphamide, and pegfilgrastim with or without bevacizumab in treating women with inflammatory or locally advanced breast cancer (NCI CDR0000636131)

1 Texas Tech University Health Sciences Center, Paul L. Foster School of Medicine, El Paso, TX; 2 SWOG Statistical Center, Seattle, WA; 3 University of Michigan, Ann Arbor, MI; 4 Seattle Cancer Care Alliance, University of Washington, Seattle, WA; 5 Mayo Clinic, Jacksonville, FL; 6 Warren Alpert Medical School of Brown University, Providence, RI; 7 Hem/Onc Consultants, Inc/Columbus CCOP, Westerville, OH; 8 Loma Linda University, Loma Linda, CA; 9 Upstate Carolina CCOP/ Spartanburg Regional Medical Center, Spartanburg, SC; 10 Yale University, New Haven, CT; 11 Arizona Cancer Center, Tucson, AZ and 12 MD Anderson Cancer Center, Houston, TX.

Body: Background. Locally advanced breast cancer (LABC) and inflammatory breast cancer (IBC) remain difficult challenges despite progress in multimodality treatment. The SWOG trial S0800 (clinicaltrial.gov NCT00856492) compared bevacizumab in combination with weekly nab-paclitaxel followed by dose-dense AC to nab-paclitaxel followed or preceded by AC as neoadjuvant treatment for HER2-negative IBC/LABC. The rationale was based on the proposed role of angiogenesis, potential role of improved flow and oxygenation in enhancing the delivery of chemotherapy agents, and the proapoptotic effect with certain chemotherapeutic agents, particularly taxanes.

Methods. This was a randomized open-label Phase II trial with an accrual goal of 200 patients equally allocated to either bevacizumab (Arm 1) or no bevacizumab. Two patients were ineligible and five withdrew consent leaving 208 for analysis. The no bevacizumab group was further randomized to two sequences (Arm 2: nab-paclitaxel - AC+PEG-G versus Arm 3: AC+PEG-G-nab-paclitaxel) with 50 patients expected in each sequence. The primary endpoint of this study was pathologic complete response (pCR) defined as no evidence of invasive tumor at the primary site and axillary lymph nodes in the surgical specimen. The power for the primary comparison of bevacizumab (bev) versus no bevacizumab (no bev) ignoring sequence was 80% with a 1-sided \( \alpha = 0.10 \). Randomization was stratified by hormone receptor status and type of disease (IBC or LABC).

Results 215 patients were accrued May 2010 - September 2012. Most had LABC (88%) versus IBC (12%) and most tumors were hormone-receptor (HR) positive (67%). Fourteen (7%) patients had no definitive surgery (included as no pCR); 135 (65%) had residual disease (no pCR) and 59 (28%) had pCR. The bevacizumab pCR rate was higher (35/96; 38%) than that in the non-bevacizumab arms (24/112; 21%) (exact \( p=0.021 \); stratified \( p=0.015 \)). In HR-positive disease there was slight improvement that was not statistically significant (bev 25% vs. non-bev 18%; \( p=0.41 \)) while the difference was larger in HR-negative disease (bev 59% vs. non-bev 28%; \( p=0.014 \)). In LABC the overall pCR rate was 29% with a higher rate in the bevacizumab patients (37% vs. 22%; \( p=0.035 \)). For IBC there was improvement (30% vs. 14%), but not statistically significant (\( p=0.61 \)) in a small sample. Overall, Grade 3 and 4 events were common in both (bev 67%; non-bev 65%), but did not differ by treatment. There were 21 deaths with 3-year overall survival (OS) of 87% and 83% for bevacizumab and non-bevacizumab, respectively (log-rank \( p=0.57 \)).

Conclusion Compared with combination anthracycline-taxane neoadjuvant chemotherapy, the Bev-Nab-paclitaxel-AC regimen significantly improved pCR rate overall, primarily for triple negative (TNBC) patients. This neoadjuvant regimen could be a good choice for TNBC/IBC. The observed pCR rate in ER negative disease (59%) suggests that the addition of bevacizumab to a standard chemotherapy backbone may improve outcome in this subset, and justifies further testing of such an approach. Correlative science studies to further delineate the biology of TNBC and the effects of bevacizumab are ongoing.
Title: Findings from the first prospective womb to breast cancer study: New gestational biomarkers support proof of concept that gestation is a window of susceptibility for the breast

Barbara Cohn1, Nickilou Krigbaum1, Lauren Zimmermann1 and Piera Cirillo1. 1Child Health and Development Studies, Public Health Institute, CA.

Body: Rationale. Here we provide the first prospective evidence for proof of concept that gestation is an important window of susceptibility for breast cancer. These findings could open the field to interdisciplinary investigation of mechanisms, and interventions via clinical and experimental science.

Objective. We tested the hypothesis that biomarkers in gestation predict early-onset breast cancer. Data were prospectively collected including maternal and paternal peri-conceptual body mass, tobacco and alcohol use, maternal pregnancy weight gain, pregnancy complications and outcomes, placental morphology assessed by a standardized examination at birth, and environmental chemicals recently assayed in archived maternal perinatal serum samples. This investigation was based on the observation of 20,000 pregnancies beginning in 1959, with surveillance for both maternal (F0) and offspring (F1) cancer in the Child Health and Development Studies pregnancy cohort. This report is based on the first 133 breast cancer cases in F1 that occurred from 1992-2012, diagnosed at ages 32 to 52.

Results. We observed gestational biomarkers of breast cancer risk which were independent of maternal history of breast cancer and race. Highlights of significant findings include independent, higher risk for women who: were born to mothers who lost weight during pregnancy (3-fold increase in risk, p<0.03), were growth retarded in utero (3-fold increased risk, p<0.01), were born with thick (p<0.01), but small diameter placentas (p<0.04), whose mothers had higher perinatal serum levels of environmental chemicals including o,p'-DDT (2.5-fold increase in risk for upper quartile, p<0.03), perfluorooctanesulfonic acid (PFOS) precursors (p<0.03) and total cholesterol (p<0.04). Maternal floor infarction of the placenta was a protective factor both for mothers and their daughters. In ancillary studies we observed that F1 breast density at mid-life is also impacted by placental morphology during F1 gestation.

Conclusions. Here we provide a high level of evidence for the existence of gestational biomarkers for breast cancer. Prospective design and direct clinical observation of pregnancies eliminates reporting and misclassification bias. Findings extend the discussion of gestational biomarkers beyond birthweight and pre-eclampsia which have been previously reported. The importance of the gestation window for breast cancer in humans is in line with toxicological evidence in animal models and strongly suggests the existence of opportunities for primary prevention beginning before birth.
Title: Efficacy of everolimus on multiple mechanisms of AI-resistance in vitro and xenograft, and characterization of their everolimus-resistance

Mariko Kimura, Natsu Fujiki, Toru Hanamura, Toshifumi Niwa, Yuri Yamaguchi, Takashi Ishikawa, Itaru Endo and Shin-ichi Hayashi. 1Graduate School of Medicine, Tohoku University, Sendai, Miyagi, Japan; 2Yokohama City University, Yokohama, Kanagawa, Japan and 3Saitama Cancer Center, Kita-adachi gun, Saitama, Japan.

Body: Background: mTOR inhibitor, everolimus showed remarkable clinical efficacy and has been considered as a promising agent for breast cancer treatment especially among hormone receptor positive (HR+) postmenopausal advanced breast cancer. Now Affinitor (everolimus) is approved for HR+ breast cancer in Japan. However, definitive biomarker has been unclear so far. In addition, the subsequent treatment after refractory to everolimus has not been defined. In preclinical study, it has been reported there are several resistant models of endocrine therapy and we also reported several types of models established from MCF-7-E10, in which estrogen receptor (ER) activity could be monitored by transfected-ERE-GFP. Those EDR cells are characterized as the followings: 1) Type 1 shows constitutive ER overexpression without estrogen, and PI3K/Akt/mTOR pathway upregulated. 2) Type 2 shows low expression of ER (ERE-GFP negative) and IGF-1R/JNK signaling pathway upregulated (Fujiki, 2014, J Steroid Biochem Mol Biol). 3) Type4, which was cultured under the condition of estrogen depletion and addition of testosterone. It showed using androgen metabolite as ligand and both PI3K/Akt/mTOR and MAPK signaling pathway upregulated (Hanamura, 2013, Breast Cancer Res Tr). Methods: Efficacy of everolimus was analyzed in those cell lines in vitro and in vivo about inhibition of cell proliferation. In vivo study, ovarectomized mice were inoculated with Type1 or Type4. Treatments were performed as single agent letrozole, everolimus, or combination and tumor volume changes were compared. Then everolimus resistant cells were generated from those EDR cells after long term exposure to everolimus in vitro. Though we could not acquire everolimus resistant cell from Type4, Type1 and 2 showed its resistance. Those everolimus resistant (EVR) cells are equivalent to resistance to the combination therapy between AI and everolimus after the first line AI treatment failure. Using those cell lines, we investigated the different mechanism of resistance to everolimus. Results: Everolimus extremely inhibited cell proliferation in each EDR type in vitro and in vivo. Besides, Type4 was more remarkably sensitive than parental MCF-7-E10 under testosterone supplemented condition in vitro. Everolimus or combination treatments reached significant tumor volume reduction around 50 percent after 21 days treatment period, in contrast to increase of tumor volume in placebo or letrozole group. In vitro study of developing resistance to everolimus, Type1-EVR cells no longer responded to everolimus and surprisingly fulvestrant also lost sensitivity to EVR cell in spite of keeping ERE activity. Type1-EVR showed much higher expression of phosphorylation of MAP-kinase than parental cell, however, MEK inhibitor or PI3K inhibitor alone was not effective but combination with fulvestrant significantly effective more than parental cell. In type2, JNK inhibitor was effective for parental cell but EVR cell lost sensitivity to JNK inhibitor, however, Src inhibitor was much more effective in Type2-EVR than in parental cell. Conclusion: Everolimus showed remarkable efficacy to any types of EDR cells, however, the mechanism of acquired resistance to everolimus was likely to be different between each EVR cell. This finding implies that different mechanisms of AI resistance follow different types of everolimus resistance.
Title: Pilot study of a passive non-radioactive electromagnetic wave technology to localize non-palpable breast lesions

Charles E Cox¹, Melissa Themar-Geck², Ronald Prati², Michelle Jung¹, Jeff King¹ and Steven C Shivers¹. ¹USF Breast Health Program, Tampa, FL and ²Breast Care Center at Florida Hospital Tampa, Tampa, FL.

Body: Background and Objectives: The standard preoperative technique for localizing non-palpable breast lesions is wire localization (WL). Radioactive seed localization (RSL) has been described as an alternative approach to address the number of clear disadvantages associated with WL. Yet, despite its proven advantages, the adoption of RSL has been impacted by considerable regulatory requirements for the handling of radioactive materials. To advance the progress made with RSL and eliminate the issues associated with radioactive components, the SAVI Scout® surgical guidance system has been developed. The SAVI Scout surgical guidance system is an FDA-cleared medical device that utilizes passive non-radioactive electromagnetic wave technology to provide real-time guidance during excisional breast procedures. The purpose of this pilot study is to determine the safety and efficacy of the SAVI Scout system in localizing and directing the removal of non-palpable breast lesions during excisional biopsy and lumpectomy procedures. The preliminary results from two institutions are reported.

Materials and Methods: Following a feasibility study using the SAVI Scout system in resected breast tissues ex vivo, Institutional Review Board approval was granted for both institutions for women with a non-palpable breast lesion requiring preoperative localization for excision. Participating patients underwent localization and excision with the SAVI Scout system, which consists of an electromagnetic wave reflective device (reflector), handpiece and console. Using mammographic or ultrasound guidance, the reflector was placed percutaneously up to 7 days prior to the scheduled excisional procedure. At surgical excision, the surgeon used the SAVI Scout handpiece to locate the reflector, which was removed along with the surrounding breast tissue. The console provides audible feedback of reflector proximity to the handpiece. Successful reflector placement, localization and retrieval were the primary endpoints.

Results: After the first training case (data not used), a total of 17 patients have participated in the study to date. The reflectors were successfully placed with mammographic guidance in 9/9 patients and with ultrasound guidance in 8/8 patients. Reflectors were placed an average of 1.7 days (range 0-6 days) before surgery. Five patients underwent excisional biopsy and 12 patients had a lumpectomy. The intended lesion and reflector were successfully removed in 17/17 patients. Reflector migration did not occur and no adverse events occurred. Of the 14 patients in which final pathology is currently available, 6 patients had no invasive or in situ carcinoma identified, 4 had no tumor in the excision, and 3/4 patients with tumor had clear margins. One patient had a focally positive margin and was recommended for re-excision.

Conclusions: The preliminary data show the SAVI Scout system to be a safe and effective tool for the localization of non-palpable breast lesions. Ongoing accrual to this pilot study will validate these findings with planned enrollment of a total of additional 50 patients in the next 60 days at up to 3 additional sites.
Title: Mature data (> 25 years) on 2 years adjuvant tamoxifen treatment in premenopausal women with breast cancer: Time to re-emphasize the progesterone receptor as predictive factor?

Maria Ekholm1,2, Pär-Ola Bendahl1, Mårten Fernö1, Bo Nordenskjöld3, Olle Stål3 and Lisa Rydén4. 1Division of Oncology and Pathology, Lund University, Lund, Sweden; 2Ryhov County Hospital, Jönköping, Sweden; 3Division of Oncology, Linköping University, Linköping, Sweden and 4Division of Surgery, Lund University, Lund, Sweden.

Body: Background
In 2011 The Early Breast Cancer Trialists' Collaborative Group (EBCTCG) reported that five years of adjuvant tamoxifen (TAM) significantly reduces the 15-year risks of breast cancer recurrence and death. Moreover, the estrogen receptor (ER) was considered the clinically most relevant predictive factor for efficacy of TAM treatment. In premenopausal patients participating in a randomized trial of 2 years of adjuvant TAM, we have previously reported on increased recurrence free survival in patients with ER- and PR-positive disease and a trend for increased overall survival in patients with PR-positive tumors. The median follow-up time was 13.9 years for patients without events. Since the effect on mortality may increase beyond year 10, we investigated more mature of data.

Aims
To investigate the long-term effect of 2 years adjuvant TAM in premenopausal patients choosing cumulative mortality (CM) and cumulative breast cancer mortality (CBCM) as end-points.

Methods
Premenopausal patients (n=564) with stage II breast cancer were included in a Swedish randomized multicenter trial between 1986-1991 and allocated to 2 years of TAM (n=276) or no treatment (n=288). The hormone receptor status of the tumor was known for 541 (96%) of the patients included, determined by immunohistochemistry or cytosol-based methods. Less than 2% were treated with adjuvant chemotherapy and they were equally distributed between the two groups. Median follow-up time was 26.3 years (22.7-29.7). Mortality data was obtained from the Swedish Cause of Death Register.

Results
Death from any cause was recorded among 312 (55%) of the patients, and 265 (47%) of the deaths were due to breast cancer. Two years of TAM decreased CM and CBCM in all patients irrespective of hormonal receptor status (n=564) (CM: HR 0.81; 95% CI: 0.65-1.02, p=0.070; CBCM: HR 0.79; 95% CI: 0.61-1.01, p=0.058), as well as in patients with ER-positive disease (n=346) (CM: HR 0.77; 95% CI: 0.57-1.03, p=0.077; CBCM: HR 0.72; 95% CI: 0.52-1.01, p=0.051), however not strictly significant. Importantly, in patients with PR-positive tumors, TAM significantly reduced CM and CBCM (CM: HR 0.73; 95% CI: 0.55-0.98, p=0.037; CBCM: HR 0.68; 95% CI: 0.49-0.94, p=0.020). Moreover, in patients with ER- and PR positive tumors TAM decreased CM (HR 0.74; 95% CI: 0.55-1.01, p=0.057) and CBCM (HR 0.69; 95% CI: 0.49-0.97, p=0.033), whereas there was no effect of TAM in patients with ER-positive and PR-negative tumors (p=0.97 and p=0.99, respectively).

Conclusions
The present study demonstrates that 2 years of adjuvant TAM as monotherapy significantly reduced CM and CBCM in premenopausal women with PR-positive tumors as well as CBCM in ER- and PR-positive tumors, after > 25 years of follow-up. Five years of adjuvant TAM have been proven to reduce mortality rates at 15 years, but we herein show that also 2 years of TAM yields a survival benefit at 25 years.

In the latest meta-analysis from EBCTCG, PR did not add predictive information in patients with ER-positive tumors, but according to our results the significance of PR, as a predictive factor for TAM efficacy, should be re-emphasized in premenopausal women.
Title: High-resolution specimen-positron emission mammography (s-PEM) indicates the spread of cancer in breast-conserving surgery

Body: Background: Breast cancer surgery, including breast-conserving surgery or sentinel lymphnode biopsy, has become minimally invasive. Recent consensus guidelines on the margins for breast-conserving surgery have defined a negative margin as one with no ink on tumor, regardless of the distance from the tumor, whereas a positive margin has ink on the tumor. Therefore, the extent of required tumor resection will decrease for cosmeses and expand the indications for breast-conserving surgery. Therefore, there is a real need for a more accurate imaging of tumor spread. In particular, a functional imaging of breast cancer specimens will help determine negative margins in breast-conserving surgery. We collaborated with Sendai Medical Imaging Center (SMIC) who have high-resolution positron emission mammography (PEM) with the novel scintillator Pr3+-doped transparent ceramic Lu3Al5O12 (Pr:LuAG) for the imaging of breast cancer specimen with 18F-fluodeoxyglucose (FDG).

Methods: With the approval of the hospital ethics committee, positron emission tomography (PET) was conducted preoperatively on the day of surgery with 18F-FDG. After the PET results were explained to the patients, breast-conserving surgery was performed in 11 patients from February to July 2014. In the operating room, medical staff exposures were calculated with a portable dosimeter. All of the cases were carried out intraoperative frozen sections that were taken from all sides of the outside of the specimens. The specimens were serially sectioned in 5-mm slices for permanent histology. After the specimens were removed, they were sent to the SMIC and high-resolution specimen-PEM (s-PEM) was conducted. We evaluated the detection rate of s-PEM in in situ or invasive lesions (extent of locations were tolerated up to a 10% error), the predictive value of margin status between s-PEM and frozen section analysis and medical staff exposure.

Results: In 11 breast specimens, eight invasive lesions and 15 in situ lesions (excluding the foci that exist in less than three carcinoma ducts) were confirmed by permanent histology. s-PEM detected all of the invasive lesions and 14 out of 15 in situ lesions. Three breast specimens had positive margins in permanent histology. Two out of three cases with positive margin accumulated 18F-FDG at the edge of the specimens, which were considered positive margins with s-PEM, whereas positive margins were only one out of three of the frozen section analysis. In contrast, a false positive margin was found in only one case with s-PEM, which confirmed the preoperative core-needle biopsy that was diagnosed as an intraductal proliferative lesion. Medical staff exposure was determined for the operator, first assistant, second assistant, anesthesiologist, scrub nurse and circulating nurse as 31, 34, 25, 11, 21 and 6 µSV, respectively.

Conclusion: s-PEM detected not only invasive lesions but also in situ lesions with great accuracy. It might accelerate the decrease in the extent of resection required in breast-conserving surgery. However, further studies are needed to elucidate the characteristics of the false positive cases in s-PEM.
Title: Triple negative breast cancer targeting paramagnetic nanoparticle for non-invasive tumor imaging

Meser M Ali¹, Nadimpalli RS Varma¹, Branislava Janic¹, Li Zhang¹ and James R Ewing¹. ¹Henry Ford Hospital, Detroit, MI.

Body: Triple-negative breast cancer (TNBC) refers to a subtype of breast cancer that is negative for estrogen receptors (ER) and/or progesterone receptors (PR), and lacks HER2 overexpression. Therefore, this subtype of breast cancer lacks the benefits of specific therapies which target these receptors. TNBC has been characterized by an acidic extracellular environment. In human aggressive breast tumors, pH has been measured by microelectrode and the values are in good agreement with the values observed in animal systems i.e. that the pH is significantly acidic in the range from 6.2 to 7.0. However, tumor intracellular pH is either neutral or alkaline. Interestingly, a similar pH gradient is not observed in normal tissues. Therefore, this acidic extracellular pH within tumor tissues can be exploited for targeted delivery of drugs and imaging agents. Recently, a pH low insertion peptide (pHLIP) derived from the protein bacteriorhodopsin has been found to target tumor acidic pH. The peptide inserts across cell membranes as an α-helix when extracellular pH (pHe) is acidic, but does not form the helix at normal or alkaline pH. Since aggressive TNBC has an acidic environment, the pHLIP will insert into the cancer cell membrane, but the pHLIP will not insert into the cell membranes of normal tissues, providing excellent specificity for targeting TNBC. Here, we demonstrate that pHLIP-tagged nanoparticles bind to and are internalized by TNBC cells in vitro. Systemic delivery of the Gd-G5-pHLIP leads to accumulation of the nanoparticles in a flank mouse model of TNBC tumor that are detected by optical and MR imaging.

We have synthesized pH-responsive MRI nanoprobe, phosphonate G5-(GdDOTA-4AmP) by following our published synthetic method. The MW of the conjugated G5 dendrimer was estimated at 79,082 g/mole by maldi-tof analysis. This corresponds to a G5-dendrimer with an average of 44 chelated Gd³⁺ ions per dendrimer. Gd44-G5 dendrimer was reacted with heterobifunctional cross-linker (sulfo-SMCC) to form reactive maleimides and then maleimide- Gd44-G5 dendrimer was coupled with C-terminus cysteine group of biotinylated Bt-pHLIP (AEQNPIYWARYADWLFTTPLLLDLALLVDADEGTGC-pegBiotin). The HABA assay with biotin and avidin revealed that on average 3.1 molecules of biotin are present in Gd44-G5-Bt-pHLIP dendrimer. Finally, Rhodamine dye was conjugated to amines surface of preloaded Gd44-G5-Bt-pHLIP3 in order to achieve final conjugate Rhodamine-Gd44-G5-Bt-pHLIP3.

To study pH-dependent translocation of molecules across the cell membrane, we have added Rho-Gd-G5-Bt-pHLIP to the cells and incubated for 3 h at pH 7.4 and 6.5. The cellular uptake of Rho-Gd-G5-pHLIP was significantly higher at pH 6.5. When Rho-Gd-G5 was used, the cellular uptake was considerable lower at both, pH 6.5 and 7.4. Hence, we have shown the ability of pHLIP peptide for intracellular delivery of Gd-G5 nanoparticles in vitro at pH 6.5 but the same ability is attenuated significantly at neutral pH. We have created a mouse model of TNBC MDA-MB-231 tumor. The pharmacokinetics of Gd44-G5-pHLIP was visualized in the MDA-MB-231 tumor over the course of 105 min post-contrast administration.
Title: RAD1901, a novel tissue-selective estrogen receptor degrader (SERD) demonstrates estrogen receptor engagement in a phase 1 clinical study

Gary Hattersley¹, Frank David¹, Alan Harris¹, Marcie Clarkin¹, Kate Banks¹, Greg Williams¹, Andor Glaudemans², Janine Doorduin², Michel Koole², Erik de Vries² and Rich Lyttle¹. ¹Radius Health, Waltham, MA and ²University Medical Center Groningen, Groningen, Netherlands.

Body: Despite advances in the treatment of metastatic breast cancer through modulation of estrogen receptor (ER) activity, after initial efficacy, the use of hormonal therapies is frequently followed by the development of de novo or acquired endocrine resistance. There therefore exists a potentially significant opportunity for new agents that can overcome endocrine resistance. One mechanism by which this could be achieved is through degradation of the estrogen receptor and thereby elimination of estrogen receptor mediated signaling. RAD1901 is a novel, non-steroidal small molecule that selectively binds and degrades the ER that is currently being evaluated for the treatment of metastatic breast cancer. RAD1901 has demonstrated good tissue selectivity in preclinical models, its does not stimulate the uterine endometrium, and it protects against bone loss in an ovariectomy-induced osteopenia rat model. In addition, we believe that RAD1901 has the ability to cross the blood-brain barrier. In vitro, treatment of tamoxifen-sensitive and resistant human breast cancer cell lines with RAD1901 resulted in a potent degradation of the ER (IC50 1.6nM in MCF7 cells) and inhibition of both basal and estradiol-stimulated proliferation. In a mouse xenograft tumor model with MCF7, oral dosing with RAD1901 resulted in a significant decrease in estradiol-stimulated tumor growth. An ongoing phase 1 clinical study in healthy volunteers is being conducted to evaluate the tolerability, safety and pharmacokinetics of RAD1901 at escalating doses. This study is also using 18F-estradiol positron emission tomography (FES-PET) to provide a pharmacodynamic assessment of estrogen receptor engagement/turnover. Following 6-days of daily treatment with RAD1901, at doses that were well tolerated, a complete suppression of FES-PET signal was observed, with standardized uptake values (SUV) comparable to background tissues. The relationship between PK and PD will be presented. To date, the maximum tolerated dose of RAD1901 has not been determined. In conclusion, RAD1901 is a novel SERD that we believe has the potential to be used for the treatment of hormone driven and hormone resistant metastatic breast cancers, including breast cancer brain metastasis. The proposed phase 1b study design in metastatic breast cancer will be outlined.

Title: Detrimental effects of sequential compared to concurrent treatment of pertuzumab plus T-DM1 in HER2+ breast cancer cell lines

James E Korkola¹, Moqing Liu¹, Tiera Liby¹, Laura Heiser¹, Heidi Feiler¹ and Joe W Gray¹. ¹Oregon Health & Science University, Portland, OR.

Body: Background. Pertuzumab and T-DM1 are two recently approved monoclonal antibody based therapies targeting HER2+ breast cancer. Pertuzumab interferes with dimerization of HER family members, while T-DM1 binds to HER2 and interferes with its oncogenic function while also specifically delivering a cytotoxic agent (emtansine). One arm of the I-SPY 2 clinical trial is to investigate the efficacy of a combination Pertuzumab plus T-DM1 in HER2+ breast cancer patients. Methods. We performed pre-clinical screening of response to each agent alone and in combination in a set of 21 HER2+ breast cancer cell lines, with an end goal of identifying markers of response to the therapies. There were five treatment regimens employed in the initial screen: i) pertuzumab alone for 72 h; ii) T-DM1 alone for 72h; iii) pertuzumab plus T-DM1 concurrently for 72h; iv) pertuzumab for 24h followed by addition of T-DM1 for 48h more; and iv) T-DM1 for 24h followed by addition of pertuzumab for 48h more. Response was assessed using the Cell Titer Glo assay as a measure of cell viability. To assess the effects of drug combinations, we used a stringent measure of synergy and antagonism employing the median effect method of Chou and Talalay that included 95% confidence intervals to determine significance. Results. Initial screens showed that concurrent treatment of cells with pertuzumab plus T-DM1 gave significant synergistic interactions in 15/21 cell lines as measured by the median effect method, with combination indices (CI) less than 0.5 (and 95% upper confidence levels less than 1.0) for at least one drug concentration. However, 24h pretreatment with pertuzumab followed by T-DM1 significantly diminished the response of cells to T-DM1, resulting in significant antagonism in 17/21 cell lines test (CI>1.5, lower confidence level greater than 1). Since this could be due to a shorter exposure time to T-DM1, and since patients are scheduled to be treated with pertuzumab first followed by T-DM1 one hour later, we repeated the experiment with one hour between pertuzumab and T-DM1 rather than 24h. While the inhibitory effect was diminished, this treatment regimen still resulted in significant antagonism when T-DM1 was given 1 hour after pertuzumab in 5/5 cell lines tested, in contrast to concurrent pertuzumab plus T-DM1 treatment, which showed synergy. Conclusions. Pertuzumab plus T-DM1 appears to be beneficial when given concurrently, but pretreatment with pertuzumab appears to blunt the efficacy of T-DM1. This has important potential ramifications for patient treatment, and may further elucidate mechanisms of action for both compounds. Further testing will be necessary to determine whether these timing effects are operational in vivo and whether immune effects mitigate the antagonism.
Title: Blocking a key region in the HER2 subdomain III inhibits the HER2-network in patients with resistance to HER2-targeted therapy

Barbara Schroeder¹, Menendez Javier², Espinoza Ingrid³ and Lupu Ruth¹. ¹Mayo Clinic Cancer Center, Rochester, MN; ²Catalan Institute of Oncology and Girona BioMedical Research Institute, Girona, Catalonia, Spain and ³University of Mississippi Medical Center, Jackson, MS.

Body: The HER2 receptor is over-expressed in about 25% of breast carcinomas and correlates with more aggressive breast cancer disease, poor prognosis as well as resistance to chemo- and endocrine therapies. The strong correlation between HER2 levels/activity and the malignancy of the disease made it a preferred target for anti-cancer therapy. For example, Trastuzumab, which targets HER2 homo-dimerization and Pertuzumab, which interferes with HER2 hetero-dimerization, are in clinical use. Unfortunately, Trastuzumab monotherapy is only partially effective and the majority of breast cancer patients who initially respond to Trastuzumab rapidly develop resistance to the drug. Thus, novel strategies/agents are in need, especially drugs that prevent hetero-dimerization with other HER family members.

Structural analyses revealed that sub-domain III in the extracellular domain (ECD) of the HER family members is responsible for dimerization. Therefore, we hypothesized that disabling the dimerization loop in the HER2-ECD sub-domain III would ultimately convert HER2 to a non-functional receptor. Therefore, we introduced a series of deletions in the HER2-ECD sub-domain III and determined their oncogenic properties compared to HER2wt expressing cells. Importantly, a small deletion (16 amino acids) of the HER2 extracellular domain (named HER2Δ6) abolished its homo- and hetero-dimerization and profoundly affected HER2-catalyzed activation of the HER network, both in the context of HER2 over-expression and ligand-induced trans-activation of HER2. Expression of the HER2Δ6 variant failed to promote anchorage-independent growth and interfered with the activation/Tyr phosphorylation of HER1, HER2 and HER3. Moreover, this mutant failed to promote resistance to Paclitaxel treatment in HER2-overexpressing breast cancer cells.

To determine the molecular mechanisms underlying this behavior, we assessed the mutant and wt expressing cells lines morphologically and biochemically and demonstrated that the HER2Δ6 is absent from the plasma membrane (PM), most likely due to a intracellular trafficking defect that mistargets the receptor to or traps it in an endomembrane compartment. Compared to HER2wt-expressing cells, the HER2Δ6 mutant proves to be even more effective in inhibiting the oncogenic properties of the receptor than the current drugs of choice such as Trastuzumab, Pertuzumab and Cetuximab alone or in combination as measured by anchorage-independent growth.

These findings reveal that the HER2-ECD bears an essential "activating" region that is indispensable for HER2 homo-and heterodimerization. Elimination of this "activating" element in HER2 seems to recapitulate and greatly improve the combined actions of Trastuzumab and Pertuzumab. These findings offer a strong rationale for developing this peptide sequence into a valuable anti-HER2 therapeutic drug.
Title: PI3K inhibitor LY294002 combined with RAD001, a mTOR specificity inhibitor, significantly reduced proliferation and induced apoptosis of triple negative breast cancer cell lines MDA-MB-231 through PI3K/Akt/mTOR pathway in vitro

SUN Gang¹,², HUAI Lei¹, MA Bin¹, DONG Chao¹ and MA Binlin¹,². ¹The Affiliated Cancer Hospital of Xinjiang Medical University, Urumqi, Xinjiang, China and ²Xinjiang Institute of Cancer Prevention and Treatment, Urumqi, Xinjiang, China.

Body: Background and purpose Research of targeted therapies about PI3K/Akt/mTOR pathway have became a hotspot recently, and related researches have been extended from a single-target suppression to multiple-targets combined inhibition. In this study, by using LY294002 and RAD001, the specific inhibitors of PI3K and mTOR, to observe whether the anti-tumor effects on the proliferation, cycle distribution and apoptosis of combined inhibitors were a synergistic effect, and were differences between different molecular characteristics of human breast cancer cells alone and in combination in vitro. Materials and Methods Routinely cultured MCF-7, SK-BR-3 and MDA-MB-231 cells in vitro. Logarithmic phase cells among each cells were selected and divided into the blank control group, LY294002 group, RAD001 group and the combination group. MTT assay and flow cytometry were used to detect the cell proliferation, cell cycle distribution and cell apoptosis of different groups. Results (1) LY294002 and RAD001 could significantly inhibit the proliferations of MCF-7, SK-BR-3 and MDA-MB-231 cells with a dose-dependent manner respectively (P<0.05), and compared with other cells, MDA-MB-231 cells were more sensitive to both drugs (P<0.05). The anti-tumor effects were significantly increased in combination groups of different cells, and showed an additive effects. (2) MCF-7, SK-BR-3 and MDA-MB-231 cells could be arrest in G1 phase by IC50 of LY294002 and RAD001 respectively(P <0.05), and the effects of combination groups were more significantly compared with monotherapy groups(P <0.05). However, no significant differences among different cells. (3) LY294002 and RAD001 could significantly increase the apoptosis rates of human MCF-7, SK-BR-3 and MDA-MB-231 cells alone (P <0.05), but there were no differences between different cells. When two inhibitors were combined, the apoptosis rates of the different cells were significantly increased compared with single drug, especially in MDA-MB-231 cell. The apoptosis rates of MCF-7, SK-BR-3 and MDA-MB-231 cells were 17.58%, 44.28% and 52.67% respectively, and there were significantly different between different cell lines (P <0.05).

Effects of LY294002 and RAD001 on the apoptosis rates of human breast cancer cell lines MCF-7, SK-BR-3 and MDA-MB-231 alone or in combination in vitro

Conclusion Targeted therapy on P13K/Akt/mTOR pathway could significantly inhibit the proliferation of human breast cancer cell lines by inducing apoptosis and arresting cell cycle distribution. By using a combination of different inhibitors which were targeted on different related genes of this pathway such as PI3K and mTOR, the anti-tumor effects were more significant increased compared with monotherapy, especially in MDA-MB-231 cell line which were negative with ER, PR and HER-2. It was important to provide new research ideas for individualized treatment and translational medicine of breast cancer.
Title: Tumor infiltrating lymphocytes and correlation with outcome in the Cher-LOB study

Maria Vittoria Dieci\textsuperscript{1,2}, Giancarlo Bisagni\textsuperscript{3}, Katia Cagossi\textsuperscript{4}, Alberto Bottini\textsuperscript{5}, Samanta Sarti\textsuperscript{6}, Federico Piacentini\textsuperscript{7}, Pierfranco Conte\textsuperscript{1,2} and Valentina Guarneri\textsuperscript{1,2}. \textsuperscript{1}Oncology and gastroenterology, University of Padova, Padova, Italy; \textsuperscript{2}Medical Oncology 2, Istituto Oncologico Veneto IRCCS, Padova, Italy; \textsuperscript{3}Azienda Ospedaliera ASMN, IRCCS, Reggio Emilia, Italy; \textsuperscript{4}Ramazzini Hospital, Carpi, Italy; \textsuperscript{5}AO Istituti Ospitalieri, Cremona, Italy; \textsuperscript{6}Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori, Meldola, Italy and \textsuperscript{7}University Hospital, Modena, Italy.

Body: Background: Tumor infiltrating lymphocytes (TIL) are emerging as a strong prognostic and predictive factor for breast cancer, especially for the HER2-positive and triple negative subtypes (Loi S, Ann Oncol 2014; Dieci MV, Ann Oncol 2014). Here we report the results of the TIL biomarker analysis performed in the CherLOB study.

Methods: The phase II neoadjuvant CherLOB study (Guarneri, J Clin Oncol 2012) randomized 121 HER2-positive, stage II-IIIA breast cancer patients to anthracyclines/taxane-based chemotherapy plus trastuzumab (arm A), lapatinib (arm B), or both (arm C). Primary endpoint was pathological complete response (pCR). Hematoxylin and eosin-stained slides from both pre-treatment biopsies and post-treatment surgical samples were centralized and evaluated for the % of intratumoral (It) and stromal (Str) TIL as previously described (Denkert C, J Clin Oncol 2010). Samples were classified as lymphocyte-predominant (LP) if ItTIL and/or StrTIL $\geq$60% and as non-LP if ItTIL and StrTIL <60%.

Results: Pre-treatment TIL evaluation was available for 105 of the 118 CherLOB patients who were assessable for pathological response. Both ItTIL and StrTIL as continuous variables (per 10% increase) were associated with a higher probability of achieving a pCR (adjusted OR: 2.64, 95%CI 1.46-4.79, $p=0.001$ and 1.32 95%CI 1.08-1.6, $p=0.006$ for ItTIL and StrTIL, respectively). pCR rates were significantly higher in LP compared to non-LP cases (59% vs 27%, $p=0.011$). According to treatment, TIL effect was more evident in patients treated with HER2 double-blockade (arm C). According to estrogen receptor (ER) status, no difference in pCR rates between LP and non-LP cases was observed in the ER-positive population, whereas pCR rate was more than doubled for ER-negative LP compared to ER-negative non-LP patients (table 1).

Overall, 71 of the 121 CherLOB patients had residual disease at surgery: for 54 of them, paired pre-treatment and post-treatment TIL were available. No significant changes in ItTIL and StrTIL levels were observed before and after treatment. However, six
cases presented a LP phenotype on the residual disease; all but one of them started from a non-LP pre-treatment phenotype and received lapatinib as part of the neoadjuvant treatment (4 arm B, 1 arm C).

Conclusions: In this analysis, TIL predicted the achievement of pCR for early HER2-positive patients undergoing neoadjuvant chemotherapy plus anti-HER2 agents. TIL predictive effect seems limited to ER-negative patients. Combinations of chemotherapy plus anti-HER2 agents containing lapatinib may be able to convert a non-LP into a LP tumor. Updating of follow-up is ongoing, correlations between TIL and survival will be presented at the meeting.
Title: Impact of tumor-infiltrating B-cell clonal diversity on response to neoadjuvant therapy in triple negative and HER2+ breast cancer treated on CALGB (Alliance) 40601 and 40603

Michael D Iglesia¹, Benjamin G Vincent¹, Jonathan S Serody¹, Lisa A Carey¹, William T Barry², William M Sikov³, Clifford A Hudis⁴, Eric M Winer⁵ and Charles M Perou¹. ¹University of North Carolina, Chapel Hill, NC; ²Alliance Statistics and Data Center, Dana-Farber Cancer Institute, Boston, MA; ³Alpert Medical School of Brown University, Providence, RI; ⁴Memorial Sloan Kettering Cancer Center, New York, NY and ⁵Dana-Farber Cancer Institute, Boston, MA.

Body: Background: Tumor infiltrating lymphocytes (TILs) are associated with improved outcomes in breast (BrCa) and ovarian cancer (OvCa). This benefit is largely restricted to the basal-like and HER2-enriched subtypes of BrCa and the immunoreactive subtype of OvCa. It is not known whether TILs respond to a small subset of antigens, similar to an antiviral or antibacterial response, or if the response is nonspecific. We developed a novel method to assess B-cell population diversity by analyzing B-cell receptor (BCR) sequence complexity in mRNA-seq datasets derived from tumor biopsies. B-cells in a subset of basal-like and HER2-enriched BrCa showed high expression of immunoglobulins coinciding with reduced BCR diversity consistent with a restricted epitope-driven immune response. Analysis of DNA patterns from B-cells in basal-like and HER2-enriched BrCa showed a greater prevalence of BCR somatic hypermutation (SHM) suggestive of an antigen-restricted response (Iglesia et al, CCR 2014). Here, we studied the impact of this adaptive immune response on treatment response.

Methods: Using two neoadjuvant cooperative group trials in triple-negative (TNBC) and HER2-positive (HER2+) BrCa, we evaluated BCR diversity (as assessed by SHM diversity) as a continuous variable and as a binary variable (diverse/restricted) relative to BCR expression (the Restriction Index) in pre-treatment tumor samples from 265 patients with HER2+ BrCa treated on CALGB 40601, a randomized phase III trial of paclitaxel plus trastuzumab +/- lapatinib, and 443 patients with TNBC treated on CALGB 40603, a randomized phase II trial of standard chemotherapy +/- carboplatin and/or bevacizumab. We examined the relationship between a restricted immune response and pCR rate, the primary endpoint of both studies, overall and within molecular subtypes.

Results: In HER2+ BrCa, the combination of high immunoglobulin expression and lower sequence diversity (high Restriction Index) was observed in 28% of the pre-treatment biopsies, and varied by intrinsic subtype, with the greatest prevalence in the HER2-enriched subset (n=80, 46% vs 20% in all others). BCR restriction predicted improved pCR rates in all patients (67% versus 37%, p <0.0001). It remained significant in the HER2-enriched subset (n = 82, p=0.0086). The impact of Restriction Index on response to chemotherapy in TNBC is being analyzed and will be presented along with multivariate models to adjust for other patient and disease characteristics and explore potential interactions.

Conclusions: The presence of a restricted diversity B-cell response in HER2+ breast cancer correlates with improved response to neoadjuvant chemotherapy plus HER2-targeted therapy, which may in part explain its impact on prognosis. We will determine if a similar correlation exists with chemotherapy response in TNBC. This suggests that immunomodulatory therapies supporting a B-cell response may be a promising therapeutic approach to targeting these tumors.
Title: The significance of tumor infiltrating lymphocyte density, subset composition and organization in breast cancer

Karen Willard-Gallo1, Laurence Buisseret1, Soizic Garaud1, Chunyan Gu-Trantien1, Alexandre de Wind1, Sébastien Duquenne1, Denis Larsimont1, Christos Sotiriou1 and Martine Piccart1. 1Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium.

Body: The clinical relevance of tumor infiltrating lymphocytes (TIL) in breast cancer (BC) has been clearly established by recent large clinical trials (presented at SABCS 2013). The relationship between protective immunity, observed in some patients, and critical features of lymphoid subset composition and organization remain unknown. Our recent work revealed that tertiary lymphoid structures (TLS), principally composed of T cells, B cells and dendritic cells, are present in the peri-tumoral regions of breast tumors and associated with a CD4+ follicular helper T (Tfh) cell presence. Through retrospective analyses, we determined that TLS were associated with good clinical outcomes in both the neo-adjuvant and adjuvant settings. To gain insight into the immune components linked with a significant TIL and TLS presence, we initiated a prospective flow cytometric study. We systematically immunophenotyped T and B cell TIL in breast tissues from tumors (n=125), non-adjacent non-tumor tissues (NANT, n=115) and normal tissue from mammary reductions (n=26) on the day of surgery. TIL organization and spatial distribution was subsequently analyzed by immunohistochemistry (IHC) and immunofluorescence (IF) on paraffin sections for a subset of patients (n=78). The fresh tissue analyses revealed that TIL density was a continuum across the 125 patients analyzed. A cutoff for TIL-positive and -negative tumors was set at 58 CD45+ TIL per mm3 of tissue based on the number of CD45+ cells present in the remarkably similar normal and NANT tissues. Applying this threshold to BC, 65% were TIL-positive with approximately one-third considered extensively infiltrated. TIL-positive tumors are characterized by an increase in CD4+ T cells and CD19+/CD20+ B cells. The median CD4/CD8 ratio was >1 in TIL-positive compared to <1 in TIL-negative tumors and NANT. CD4+ and CD8+ T cells were predominantly CD45RO+ memory cells, with a significant proportion expressing PD-1. Infiltrating B cells were approximately 50% memory cells in contrast to <15% in normal and NANT tissues. Extensively infiltrated tumors were more frequently associated with Tfh and follicular B cells resident in TLS. IF analysis by confocal microscopy found that TLS resident cells included specific lymphocyte subsets: marginal B cells (CD20+CD27+IgD−), follicular mantle B cells (CD20+IgD+), germinal center B cells (CD20+Ki67+CD35+CD21+PD-1+) and germinal center Tfh cells (CD4+CD200+TIGIT+CXCL13+) in a B cell zone surrounded by a T cell zone containing CD4+ and CD8+ T cells. To determine whether the flow cytometry data was correlated with routine pathology, sections of the same tumors were stained by H&E and CD45 (total leukocytes) or CD3 plus CD19 (T cells + B cells; >95% of CD45+ cells) IHC and scored by trained pathologists. The best correlation was observed between CD3/CD20 flow cytometry and CD3/CD19 IHC, the latter also associated with lower inter-observer variability. TIL density was positively correlated with proliferation (Ki67 & histological grade) and hormone receptor negativity while TLS were more frequent in younger women. These data suggest that organized immune responses in TLS adjacent to the tumor bed provide an effective location for generating anti-tumor memory T and B cell responses.
Somatic leukemogenic mutations associated with infiltrating white blood cells in breast cancer patients

Elizabeth A Comen¹, Maria Kleppe¹, Hannah Wen¹, Britta Weigelt¹, Lennart Bastian¹, Brian Blum¹, Franck T Rapaport¹, Matt Keller¹, Nicolas Socci¹, Agnes Viale¹, Daoqi You¹, Robert Benezra¹, Edi Brogi¹, Jorge Reis-Filho¹, Michael Berger¹, Ross Levine¹ and Larry Norton¹. ¹Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Background: In the last few decades, theoretical models of cancer growth and progression have long focused on the aberrations of cancer cells alone, such as the abnormal mitotic and invasive characteristics of cancer cells. More recent research across multiple solid tumors suggests a critical interplay between solid tumors and immune regulating cells. Mounting evidence suggests that the immune system can tip the scales of cancer progression, eliciting either an anti-tumor or pro-tumor immune response depending upon varying stimulating and inhibitory factors. Here, we are the first to demonstrate novel mutations including leukemogenic mutations among tumor infiltrating lymphocytes in breast cancer patients.

Methods: We obtained 17 primary breast cancer samples from patients who presented for either a lumpectomy or mastectomy as part of an IRB approved biospecimen protocol. Of the 17 patient samples, 13 had triple negative breast cancer, 2 had ER+, HER2+ disease, and 2 had ER+, HER2- disease. In the 17 samples, we used fluorescent activated cell sorting to separate CD45-positive hematopoietic cells from CD45-negative epithelial cells. We then performed exome sequencing of tumor-infiltrating hematopoietic cells to investigate for the presence of pathogenic mutations in tumor-associated leukocytes. In this first step, we identified candidate mutations in known cancer genes, including BCOR, NOTCH2, TET2, NF1, EZH2, and JAK1. As a validation step, we then performed capture-based sequencing of tumor-infiltrating leukocytes in 20 breast cancer samples matched to each patient’s germline DNA sample (buccal swab). In 10 of the 20 patients, we identified and validated somatic mutations. Of note, 6 of these patients harbored mutations known to be associated with leukemia, including DNTM3A, TET2, and BCOR. Most of these mutations were present in at least 5-20% of reads. This suggests that these mutations were present in enriched subclones and were not rare alleles occurring in a minority of hematopoietic stem cells. Lastly, we performed 454 deep sequencing analysis of microdissected tumor DNA samples and confirmed the absence of these mutations in breast cancer cells.

Conclusion: Our data demonstrate somatic mutations in tumor infiltrating leukocytes in breast tumors which were not identified in matched germline or tumor DNA samples. Notably, some of these mutations have been implicated in the pathogenesis of lymphoid and myeloid malignancies. This observation suggests a unique relationship between cancer cells and mutant infiltrating leukocytes. We are now investigating the functional interaction between cancer cells and hematopoietic cells. Our findings reframe our understanding of carcinogenesis and offer novel opportunities for cancer detection and treatment.
Title: Characterizing the Tumor Immune MicroEnvironment (TIME) in high-risk ductal carcinoma in situ

Michael J Campbell¹, Rita Mukhtar¹, Ekene Obi-Okoye¹, Booyeon Han¹, Vickram Tandon¹, Sarah Zheng¹, Zelos Zhu¹, Max Endicott¹, Max Wicha², Linda Lindstrom¹, Alfred Au¹, Frederick Baehner¹, Joe Gray³ and Laura Esserman¹. ¹University of California, San Francisco, CA; ²University of Michigan, Ann Arbor, MI and ³Oregon Health & Science University, Portland, OR.

Body: Background: Ductal carcinoma in situ (DCIS) of the breast is a premalignant condition. Although DCIS is treated as an obligate precursor of invasive ductal carcinoma, the rate and latency of progression from DCIS to invasive breast cancer (IBC) in the absence of treatment are unknown. DCIS is not one condition, but rather a spectrum of disease and although DCIS itself is not a lethal condition, women with DCIS are at higher risk of developing subsequent IBC over a time period of 1-20 years depending on DCIS subtype. Features of DCIS that are associated with high risk of recurrence include large size (> 5cm), high grade, comedo necrosis, palpable mass, hormone receptor (HR) negativity, and HER2 positivity. The objective of this study was to characterize the tumor immune microenvironment (TIME) of these high-risk DCIS lesions.

Methods: Forty-eight cases of high grade DCIS, enriched for large, confluent lesions and history of recurrence were age matched with 64 cases of non-high grade DCIS. IHC analyses were performed as single or two-color stains for the following antigens: CD68, CD8, CD4, CD20, HLA-DR, CD115, FoxP3, PCNA, Mac387, MRC1, ALDH, CD24, CD44, Ki-67, and HER2. HR status was determined from ER and PR staining results in pathology reports. A Nuance multispectral imaging system was used to image and spectrally unmix each stain. Protocols for automated image analysis were developed using CellProfiler software. Associations between immune cell populations and clinical parameters (tumor palpability, recurrence, HR status, HER2 status, and Van Nuys score [12-point scale: margins, age, size, grade]) were identified with non-parametric Spearman correlation tests.

Results: We found a high macrophage infiltrate associated with a high Van Nuys score, palpability, and high Ki-67. High CD115 (CSF-1 receptor) was associated with HER2+, high Ki-67, and recurrence. Mac387+ cells and FoxP3+ regulatory T cells (Treg) were associated with high Van Nuys score, comedo necrosis, high Ki-67, HR- and HER2+. Interestingly, both Mac387 and CD115 were expressed on tumor cells as well as macrophages and high CD115 staining on tumor cells was associated with recurrence. The presence of CD8+HLA-DR-negative T cells throughout a section was associated with high Van Nuys score, HR-, HER2+, and recurrence. In contrast, CD8+ T cells within the nests of tumor cells were negatively associated with Van Nuys score, palpability, and comedo necrosis. A tumor immune microenvironment score (TIME score) was developed based on the proportions of various immune cell populations. A high TIME score was significantly associated with high Van Nuys scores as well as with recurrence.

Summary: These results demonstrate that high risk DCIS features (palpability, high Van Nuys score, high proliferation, HR-, HER2+, and increased recurrence) are associated with a suppressed tumor immune micro-environment (high FoxP3+ cells, CD68+Mac387+ cells, CD8+HLA-DR-neg T cells, and upregulated CD115). These high risk lesions truly represent an opportunity to prevent cancer. Identifying these high risk lesions with the help of tumor immune microenvironment markers and manipulating the DCIS TIME via local or systemic immunotherapeutic strategies may represent an ideal preventative intervention.
Inhibition of PD-L1 by MPDL3280A leads to clinical activity in patients with metastatic triple-negative breast cancer

Leisha A Emens¹, Fadi S Braiteh², Philippe Cassier³, Jean-Pierre DeLord⁴, Joseph Paul Eder⁵, Xiaodong Shen⁶, Yuanyuan Xiao⁶, Yan Wang⁶, Priti S Hegde⁶, Daniel S Chen⁶ and Ian Krop⁷. ¹Johns Hopkins University, Baltimore, MD; ²Comprehensive Cancer Centers of Nevada, Las Vegas, NV; ³Centre Léon Bérard, Lyon, France; ⁴Institut Claudius Regaud, Toulouse, France; ⁵Yale School of Medicine, New Haven, CT; ⁶Genentech, San Francisco, CA and ⁷Dana-Farber Cancer Institute, Boston, MA.

Body: Background: Metastatic triple-negative breast cancer (TNBC) is associated with a poor prognosis and has no targeted therapy options. Programmed death-ligand 1 (PD-L1) expression is more prevalent in TNBC than in other breast cancer subtypes. PD-L1 may protect cancer cells from immune-mediated destruction by binding to its receptors PD-1 and B7.1. MPDL3280A, a human anti-PD-L1 monoclonal antibody with an engineered Fc-domain designed for optimized efficacy and safety, blocks PD-L1 activity and restores tumor-specific T-cell immunity.

Methods: This multicenter Phase I study selectively enrolled a cohort of patients with PD-L1-positive metastatic TNBC. PD-L1 positivity was centrally evaluated based on the PD-L1 immunohistochemistry (IHC) status of tumor-infiltrating immune cells (ICs). Eligible patients received MPDL3280A 15 or 20 mg/kg IV every 3 weeks for up to 1 year. The objective response rate (ORR) was assessed by RECIST v1.1. MPDL3280A immune correlates were evaluated for tumor and circulating biomarkers. The clinical data cutoff was January 1, 2014.

Results: Twelve patients were treated with MPDL3280A and evaluable for safety. Patients had ECOG PS 0-1 (33% ECOG PS 1), and the median age was 55 years (range, 29-72 years). All 4 patients (33%) with visceral metastases had liver metastases, and 1 patient (8%) had bone metastases. 92% of patients received ≥ 2 prior therapies. Prior chemotherapies included anthracycline (92%), taxane (75%) and platinum (42%). Grade 3-4 treatment-related adverse events (AEs) occurred in 8% of patients (1 event of Grade 3 adrenal insufficiency). One patient had an immune-related AE (Grade 2 pyrexia). No treatment-related deaths were observed. Nine patients were dosed by November 16, 2013 and evaluable for efficacy. The ORR was 33%, including 1 CR and 2 PRs. Responders included patients with visceral metastases at baseline. At the time of the clinical data cut-off, all responses occurred within 6 weeks of the first dosing of MPDL3280A, and all of the responses were ongoing. The median duration of response had not been reached. One patient achieved stable disease as best response. Two additional patients had tumor shrinkage (-43% and -44% change in target lesions, respectively) but were not counted as RECIST responders due to the appearance of new lesions, which is likely attributable to pseudoprogression. Preliminary pharmacodynamic biomarkers related to MPDL3280A activity, including circulating plasma markers and tumor immunomonitoring with CD8 IHC, will be presented along with updated clinical data.

Conclusions: MPDL3280A treatment was well tolerated and was associated with objective clinical activity in patients with pretreated metastatic TNBC. Further evaluation of the safety and clinical activity of MPDL3280A in both PD-L1-positive and PD-L1-negative metastatic TNBC is ongoing. Clinical trial information: NCT01375842.
Title: Differential expression of innate and adaptive immune responses in TNBC outcome

Yesim Gokmen-Polar1, Xianyin Lai1 and Sunil Badve1. 1Indiana University School of Medicine, Indianapolis, IN.

Body: Introduction:
Clinical management of patients with triple-negative breast cancers (TNBCs) presents a significant challenge. TNBCs tend to relapse early and exhibit poor prognosis compared to other breast cancer subtypes. Recent studies emphasize the influence of the immune system in prognosis of TNBCs. In particular, the percentage of tumor infiltrating lymphocytes (TILs) is associated with breast cancer prognosis and outcomes after conventional therapy in triple negative tumors. However, the biology underlying this immune response is unclear.

Methods:
To identify differential expression of key immune response markers in TNBC with clinical outcome, we have performed a three-step approach as follows: 1) quantitative LC-MS/MS proteomic analysis using 16 formalin-fixed paraffin-embedded (FFPE) triple negative tumors with prognostic outcome and Ingenuity Pathway Analysis (IPA) performed to determine the biological processes and networks, 2) in silico analysis of prognostic value (10 year- DFMS) with the expression levels of 96 immune response genes using large cohorts of publicly available gene expression datasets (11 Affymetrix datasets), and 3) integrating the quantitative LC-MS/MS proteomic analysis with the in silico analysis to further understand the relation between the type of immune response including innate and adaptive immune responses.

Results:
LC-MS/MS proteomic analysis identified and quantified a total of 1,560 proteins of which 254 were differentially expressed in TNBC tumors with poor prognosis compared to good prognosis (P≤0.05). IPA analysis revealed inflammatory response and immunological processes as top differentially regulated biological functions in these tumors [P ranging between 7.41E-10 - 8.05E-03 (53 proteins) and 2.59E-09 - 5.80E-03 (69 proteins), respectively)]. The top altered immunologic networks included "Immune cell trafficking" and "cell-mediated immune response". Among the differentially regulated markers from both analyses, osteopontin (OPN or SPP1), STAT1, and MX1 remained highly significant in both proteomic and in silico analyses (P<0.008). Interestingly, many components of the innate immunity (i.e TLRs) and adaptive immunity (Th2 response, Th17, T-reg, T cell activation, and related cytokines) did not reach statistical significance in combinatorial analysis.

Conclusion:
Integrated in silico and proteomic analysis provides clues regarding the relative importance of immune pathways associated with response in breast cancer. This will enable targeting of immune therapies to improve the functionality of the pathways and ultimately in choosing the right patient TNBC subgroup for potential therapeutics, thereby improving the clinical outcome.

Body: Purpose
The NSABP B-40 study was designed to determine whether the addition of capecitabine (X) or gemcitabine (G) to neoadjuvant docetaxel (T) followed by AC increased pathologic complete response (pCR) rates and improved outcomes of women with operable, HER2-negative breast cancer. In addition, B-40 was to determine whether the addition of neoadjuvant plus adjuvant bevacizumab (Bev) to T-based regimens followed by AC would increase pCR and improve outcomes. The pCR results and toxicities have been reported previously. The DFS and OS results are reported here for the first time.

Methods
Patients (Pts) received one of three T-based regimens for 4 cycles: T 100 mg/m2 day 1; T 75 mg/m2 day 1 and X 825 mg/m2 BID days 1-14; or T 75 mg/m2 day 1 and G 1000 mg/m2 days 1 and 8. Pts then received preoperative AC x 4 cycles. Pts randomly assigned to the Bev groups received Bev at 15mg/kg, q3wks x 6 with the first 6 courses of neoadjuvant chemotherapy and were to resume Bev post-operatively for 10 doses. 1,206 pts were assigned and 1,163 of them were clinically eligible and had follow-up. The cutoff date for data presented here was March 31, 2014. The median follow-up was 4.7 years.

Results
Neither X nor G added to neoadjuvant chemotherapy increased DFS or OS. 50% of Bev pts for whom treatment data were available (577) completed 10 doses of post-op Bev; 26% did not start Bev post-op. Addition of Bev significantly increased OS (HR=0.70, p=0.01) and marginally increased DFS (HR=0.81, p=0.06). The effect of Bev was most notable in women with hormone receptor positive (HR+) breast cancers (DFS HR=0.71, p=0.04; OS HR=0.63, p=0.03).

Conclusions
Addition of G or X to neoadjuvant T + AC had no significant impact on DFS or OS. Bev added to neoadjuvant chemotherapy and continued post-operatively marginally increased DFS in the overall cohort, with a significant increase in DFS in the HR+ subset. The addition of bevacizumab significantly improved OS for women with operable HER-2-negative breast cancer. In agreement with previously reported results for pCR, the improvement in DFS and OS was seen preferentially in women with HR+ breast cancers.

**Body:**

**Background:** In the metastatic and neoadjuvant settings, BEV improves PFS and pCR rates, respectively, when combined with chemotherapy (CT) for breast cancer. However, in the adjuvant setting invasive disease-free survival (IDFS; primary outcome measure) was not improved by adding 1 year of BEV to CT in the open-label randomized phase III BEATRICE trial in early TNBC (stratified hazard ratio [HR] 0.87 [95% CI 0.72–1.07]). We report final efficacy and updated safety results.

**Methods:** Eligible patients (pts) had centrally confirmed triple-negative and/or basal-like operable primary invasive breast cancer (pT1a–pT3). Investigators selected anthracycline (anth)- and/or taxane (tax)-based CT for each pt. After definitive surgery, pts were randomized 1:1 to receive ≥4 cycles of either CT alone or the same CT + 1 year of BEV (5 mg/kg/wk equivalent). Stratification factors were nodal status (0 vs 1–3 vs ≥4 involved nodes), selected CT (anth vs tax vs both), hormone receptor status (negative vs low), and surgery (breast conserving vs mastectomy). Secondary outcome measures included overall survival (OS) and safety (CTCAE v3.0). Final OS analysis was prespecified after median follow-up of ∼5 years, ∼76 mo after the first pt was randomized, or after 340 deaths, whichever occurred first.

**Results:** At the data cut-off (June 30, 2014), median follow-up was 56 mo; 293 of 2591 randomized pts had died (86% of estimated events for the final analysis). There was no statistically significant difference in OS between treatment arms either overall or in prespecified subgroups (Table). 5-year OS rates were 88% (95% CI 85.7–89.6%) with CT alone and 88% (95% CI 86.0–89.8%) with CT–BEV. Updated IDFS results (exploratory analysis) were consistent with the primary IDFS analysis. 5-year IDFS rates were 77% (95% CI 74.4–79.4%) with CT alone vs 80% (95% CI 77.2–81.9%) with CT–BEV. New grade ≥3 AEs occurred in 4.6% and 4.5% of pts, respectively, in the period from 18 mo after first study dose to study end.

**Conclusions:** The final OS analysis after 293 deaths showed no significant benefit from the addition of BEV to standard adjuvant CT for early TNBC. Updated IDFS results were similar to the primary IDFS results, showing no difference between treatments. Late-onset AEs were rare in both groups. 5-year IDFS and OS rates suggest that the prognosis for pts with TNBC is better than previously thought.

**Body:** Background: Bevacizumab (bev) has been used with neo-adjuvant chemotherapy (NACT) in breast cancer trials. Geparquinto reported benefit for bev in triple negative (neg) patients (pts) (pathological complete response (pCR) 36.4% vs 27.8% p=0.02), as did CALGB 40603 (pCR 52% vs 44%, p=0.057), although NSABP-B40 showed benefit in ER positive (pos) pts (pCR 23.3% vs 15.2%, p=0.008).

Methods: ARTemis is a randomised phase 3 trial adding bev to NACT (docetaxel (D)-FEC). Pts with HER2-neg invasive breast cancer were eligible. Stratification was by age, ER status (neg:weak pos:strong pos), tumour size (T2:T3/4), clinical involvement of axillary nodes and inflammatory/locally advanced disease. Pts were randomised (1:1) to bev+D-FEC or D-FEC. The primary endpoint was pCR, defined as no residual invasive cancer in the breast or axillary lymph nodes after NACT. 800 pts were required to detect 10% differences in pCR rates; 85% power, 5% alpha level.

Results: 800 pts were randomised from 66 UK centres (May 2009 to Jan 2013). 68% were <50 years old, 19% had inflammatory and/or locally advanced disease, 79% of tumours <50mm, 52% clinical node pos and 33% ER-neg. A 2-reader independent review of pathology reports determined whether pCR had been achieved or, at least, minimal residual disease (MRD) status. Significantly more pts on bev+D-FEC had a pCR (22% vs 17%; adjusted p=0.03) (see table). pCR rates differed significantly across ER groups (neg 38%, weak pos 39%, strong pos 7%; p<0.0001). Treatment effect of bev remained significant after adjustment for ER (p=0.03). Similarly significantly more pts on bev+D-FEC had a pCR or MRD (36% vs 29%; adjusted p=0.035). Rates differed significantly across ER groups (neg 51%, weak pos 58%, strong pos 18%; p<0.0001). Treatment effect of bev remained significant after adjustment for ER (p=0.03).

Conclusions: ARTemis showed a significant improvement in both pCR and MRD rates with the addition of bev to D-FEC. ER-neg and ER-weak pos / HER2-neg breast cancer pts appeared to benefit most from bev, whilst pCR and MRD rates in ER-strong pos pts were lower and did not appear to benefit from bev. Our results are similar to those reported in Geparquinto and CALGB 40603.
Title: Subgroup efficacy analyses of the randomized phase III TANIA trial evaluating continued or reintroduced bevacizumab (BEV) after 1st-line BEV for HER2-negative locally recurrent/metastatic breast cancer (LR/mBC)

Fabio Puglisi1, Javier Cortes2, Eduard Vrdoljak3, Joseph Gligorov4, Norbert Marschner5, Christoph Zielinski6, Michele de Laurentiis7, Etienne Brain8, Christelle Lévy9, Anja Welt10, Zsuzsanna Kahan11, Moshe Inbar12, Sabine de Ducla13,UFriedensprung13 and Gunter von Minckwitz14,15. 1University Hospital of Udine, Udine, Italy; 2Vall d’Hebron University Hospital, Barcelona, Spain; 3University Hospital Split, Split, Croatia; 4APHP Tenon, IUC-UPMC, Paris, France; 6Outpatient Cancer Center, Freiburg, Germany; 6Comprehensive Cancer Center, Medical University Vienna and CECOG, Vienna, Austria; 7INT Fondazione G Pascale, Naples, Italy; 8Centre Curie et Hôpital René Huguenin, Saint-Cloud, France; 9University Hospital of Szeged, Hungary; 10Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; 11F. Hoffmann-La Roche Ltd, Basel, Switzerland; 12German Breast Group, Neu-Isenburg, Hessen, Germany and 15University Women's Hospital, Frankfurt, Germany.

Body: BACKGROUND: The open-label randomized phase III TANIA trial demonstrated statistically significantly improved progression-free survival (PFS; primary endpoint) with the addition of BEV to 2nd-line chemotherapy (CT) in patients (pts) with HER2-negative LR/mBC progressing after 1st-line BEV-containing therapy. We describe efficacy in clinically relevant subgroups to assess consistency of the BEV treatment effect.

METHODS: Pts whose HER2-negative LR/mBC had progressed during/after 1st-line BEV–CT were randomized 1:1 to investigator's chosen 2nd-line single-agent CT given either alone or with BEV (15 mg/kg q3w or 10 mg/kg q2w). 2nd-line therapy was continued until disease progression (PD), unacceptable toxicity or consent withdrawal. At PD, BEV was continued with 3rd-line CT (investigator's choice) in pts initially randomized to BEV–CT but was not permitted in pts randomized to CT alone. The primary endpoint was PFS from randomization to 2nd-line PD/death. Sample size was calculated based on a log-rank test assuming median PFS of 7–9.3 mo with a corresponding hazard ratio (HR) of 0.75. PFS events were required in 384 of 488 pts for 80% power at 2-sided α=0.05. Subgroup analyses of the primary endpoint were prespecified and included subgroups defined by stratification factors.

RESULTS: From Jan 2011 to Apr 2013, 494 pts were enrolled. The data cut-off for the primary analysis was Dec 20, 2013 (median follow-up: CT 15.9 mo; BEV–CT 16.1 mo). The PFS benefit seen in the overall population was observed consistently in most subgroups.

CONCLUSIONS: PFS was statistically significantly improved with the addition of BEV to 2nd-line CT in BEV-pretreated pts, meeting the primary objective of TANIA. This effect was seen consistently within subgroups based on stratification factors. Within the limitations of exploratory subgroup analyses with small sample sizes, further subgroup analyses may suggest some potential inconsistencies in treatment effect. These hypothesis-generating observations require further exploration of potential differences in disease and pt characteristics in TANIA, which may have influenced physicians' CT choice.
Title: Epidemiology of stage IV breast cancer patients: A review of the National Cancer Database 2000-2011

Jessica Gries¹, Van Do TH² and Peter Silberstein¹,². ¹Creighton University School of Medicine, Omaha, NE and ²VA Omaha Medical Center, Omaha, NE.

Body: Background: Breast cancer patients tend to have distinctive characteristics that change as the cancer progresses to stage IV, especially in race and socioeconomic status. A previous SEER-based study reported blacks were diagnosed with a more advanced stage and larger tumor size compared to white patients'. This is the largest study to determine multiple factors associated with patients presenting with stage IV breast cancer.

Methods: A population-based study was conducted using the National Cancer Database (2000-2011), which contains 70% of all cancer diagnoses in the United States from 1658 American College of Surgeons Accredited-Hospitals. The initial diagnosis of stage IV disease in women represented 3.56% (81,476) of the total patient population (2,294,058). The demographics of the stage IV patients were compared to the entire database (all stages) of breast cancer patients using the chi square test.

Results: There was an increased incidence of stage IV Breast Cancer in patients with the following characteristics: Black, no insurance, Medicaid, Medicare, less educated, lower household income, and higher comorbidity (Table-1). Stage IV cancer incidence was higher in black patients (17%) compared to all stages (10%). There were 5,137 more black patients with stage IV than expected. Stage IV patients are three 3x more likely to have no insurance and 2x as likely to have Medicaid when compared to all stages. Stage IV patients tend to have less education and were twice as likely to have 2+ comorbidities. There was no increased incidence of stage IV disease in either Hispanics or in different age groups, and only a slight difference in distance traveled (not shown in table).

Conclusion: The following characteristics are more common in patients with stage IV disease: low income, Black, no insurance, Medicaid, less education, and higher comorbidity. Patients who were White, had private insurance, higher education and income status, and lower comorbidity had less representation in stage IV disease. These factors influence the occurrence of a more advanced stage of the disease. Identifying or more promptly treating patients in high-risk populations may reduce their incidence of stage IV disease.

**Average Grade:** 0

**Title:** IMMU-132, a new antibody-drug conjugate (ADC) against Trop-2, as a novel therapeutic for patients with relapsed/refractory, metastatic, triple-negative breast cancer (TNBC): Results from Phase I/II clinical trial (NCT01631552)

Aditya Bardia¹, Alexander Starodub², Rebecca L Moroose³, Ingrid A Mayer⁴, Jennifer R Diamond⁵, Ellen Chuang⁶, Serengulam V Govindan⁷, Robert M Sharkey⁷, Pius Maliakal⁷, William A Wegener⁷, Steven A Hamburger⁷, Allyson J Ocean⁷, David M Goldenberg⁷,⁸ and Linda T Vahdat⁷. ¹Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA; ²Indiana University Health Center for Cancer Care, Goshen, IN; ³UF Health Cancer Center, Orlando, FL; ⁴Breast Cancer Program, Vanderbilt-Ingram Cancer Center, Nashville, TN; ⁵University of Colorado Cancer Center, Aurora, CO; ⁶Weill Cornell Medical College, New York, NY; ⁷Immunomedics, Inc, Morris Plains, NJ and ⁸Garden State Cancer Center, Center for Molecular Medicine and Immunology, Morris Plains, NJ.

**Body:**

**Background:** TNBC, comprising 15-20% of all invasive breast cancers, represents an aggressive phenotype with high risk of recurrence and mortality. Trop-2 is a cell-surface glycoprotein expressed on many human carcinomas, including TNBC. High Trop-2 expression is associated with more aggressive disease and poor prognosis in several cancers, including breast cancer. We report interim results from a Phase I/II trial evaluating a novel ADC, IMMU-132 (isactuzumab govitecan), comprising a humanized anti-Trop-2 antibody conjugated to the topoisomerase I inhibitor, SN-38 (active metabolite of irinotecan). The drug:antibody ratio of 7.6 facilitates the delivery of high-dose chemotherapy preferentially to the tumor cells.

**Methods:** Patients (pts) with relapsed/refractory metastatic epithelial tumors were enrolled at escalating IMMU-132 doses (8 to 18 mg/kg), given on days 1 and 8 of a 21-day cycle. The Phase II dose at this schedule was 10 mg/kg. CT scans were performed every 6-8 weeks to assess response using RECIST 1.1. During the dose-escalation portion, evidence of antitumor activity, including 3 partial responses (TNBC, small-cell lung cancer and colorectal cancer) and many with durable stable disease (SD), was observed, leading to Phase II expansion.

**Results:** As of Sept. 25, 2014, a total of 132 pts have been enrolled, including 30 with advanced/metastatic TNBC. Currently evaluable TNBC pts (N=17) had a median age of 50 (33-77), with a median of 4 prior drug regimens (range 1-8), and 67% having received prior platinum-containing regimens. In this heavily pre-treated population, there were 4 PRs (25%) and 9 SDs (56.3%) per RECIST v1.1, representing a disease control (PR+SD > 4 mos) of 53% among evaluable pts with adequate follow-up. A maximum shrinkage of target lesions of 33%, 44%, 51%, and 60% for pts with PRs, and 14%, 19%, and 27% for 3 pts with SD, was determined. Biomarker CA15.3 directional changes correlated with RECIST. All but one pathology specimen were Trop-2+ by immunohistochemistry. HPLC analysis of serum samples found <5% unbound SN-38. The half-life of IMMU-132 was 23 h, which is similar to the predicted half-life from in vitro serum stability studies. Grade 3/4 toxicities were: neutropenia (G3, 4 pts, 23.5%) with 1 febrile neutropenia (5.9%), and lymphocytopenia (1 Gr 3, 1 pt, 5.9%). Grade 1/2 events were fatigue (35.3%), diarrhea (41.2%), and alopecia (29.4%). No pt discontinued therapy due to toxicity.

**Conclusions:** Based on laboratory and initial clinical results, IMMU-132 is an ADC that selectively delivers a topoisomerase I inhibitor to cancer cells without the need for enrichment by a companion diagnostic. It is safe, well-tolerated, with preliminary evidence of encouraging efficacy in heavily-pretreated pts with relapsed/refractory metastatic TNBC. Randomized Phase III and combination trials are being planned.
**Title:** Evaluation and clinical impact of intra-tumor heterogeneity (ITH) in primary HER2-overexpressing breast cancers (HER2+BC) treated with adjuvant trastuzumab and chemotherapy (CT)

Sherene Loi¹, Peter Savas¹, Ingrid Lonnstedt², Debora Fumagalli³, Franco Caramia¹, Jason Li¹, Roberto Salgado³, Andrew Rowan¹, Fabrice André⁵, Carsten Denkert⁶, Patrick Neven⁷, Sibylle Loibl⁸, Christos Sotiriou³, Charles Swanton⁴ and Terence P Speed². ¹Peter MacCallum Cancer Centre, East Melbourne, Victoria, Australia; ²Walter and Eliza Hall Medical Research Institute, Parkville, Victoria, Australia; ³Institute Jules Bordet, Brussels, Belgium; ⁴Translational Cancer Therapeutics Laboratory, Cancer Research, London, United Kingdom; ⁵Gustave Roussy, Villejuif, France; ⁶Charité Hospital, Berlin, Germany; ⁷UZ Leuven, Gasthuisberg, Leuven, Belgium and ⁸German Breast Group Forschungs GmbH, Neu-Ilsenburg, Hessen, Germany.

**Body:** Background: Despite the success of trastuzumab, when added to CT, for the treatment of women with primary HER2+ BC, diversity in clinical responses and survival are still observed. ITH or the presence of subclonal populations is theorized to be a cause of drug resistance. In this study, we investigated if ITH that could be estimated from a single sample taken at primary surgery from patients with newly-diagnosed HER2+ disease and if ITH was associated with poorer clinical outcomes despite adjuvant trastuzumab-based treatment.

**Methods:** Fifty-two frozen tumor and matched germline samples were taken from patients diagnosed with primary HER2+BC and treated with adjuvant trastuzumab and CT with a median follow-up of 6.3yrs (range 1.5-13). There were 10 (19%) invasive relapses, 7 (13%) distant relapses and 5 (9.6%) deaths. We performed tumor and germline whole exome sequencing (WES), tumor and germline copy number (CN) data profiling (Affymetrix SNP6.0), tumor gene expression (Affymetrix U133 2.0Plus). Variants were called with MuTect, CNs were called using GISTIC. We developed a novel bioinformatics method that integrated WES variant allele fractions, purity estimates and SNP data to delineate the presence of single or multiple genetically distinct subclones. We confirmed our estimated tumor ploidy using flow cytometry on 9 samples. We investigated the association between the presence of ITH and survival using multivariate Cox regression analyses.

**Results:** We observed in HER2+ BCs the presence of substantial chromosomal instability, numerous CN alterations and aneuploidy. With regards to their genomic architecture, 76.9% (40/52) displayed the presence of at least one aneuploid subclone, where the median ploidy was 3.3 (range:1.7-6.3) copies. Multiple distinct subclones or the presence of ITH could be clearly detected in 35/52 (67.3%) samples, 8/52 (15.4%) had evidence of only a single clone, whilst in 9/52 (17.3%) samples their genomic structure could not be definitively determined. The existence of ITH was significantly associated with invasive relapse after adjustment (HR:4.38;95%CI:1.61-7.14;p=0.002) with estrogen receptor and nodal status also remaining significant in the Cox model—in contrast, the absence of ITH was associated with excellent outcomes (no distant relapses). Other surrogates of genomic instability (gene expression signature [CIN70] and SNP signature [Genomic Instability Index]) were not significantly associated with survival in this dataset.

As exploratory analyses, potential genetic drivers of ITH were investigated. *PIK3CA* (n=13,p=0.008), *MED1* (n=3,p=0.03) and *IKZF1* (n=3,p=0.03) mutations, amplifications in 8q22.2 (n=7,p=0.008) as well as deletion in 1q24.2 (n=5, p=0.006) were associated with the presence of a single clone, whereas we did not find any genetic drivers with significant associations with ITH.

**Conclusions:** We show for the first time that the presence of ITH in primary HER2+ tumors is associated with worse outcomes despite adjuvant trastuzumab and CT. These findings should be evaluated in larger cohorts.
Title: Broad exonic DNA diversity is associated with resistance to taxane-FAC chemotherapy in triple negative breast cancer

Tingting Jiang¹, Weiwei Shi¹, William F Symmans², Charles Li¹, James Platt¹, Rosanna Lau², Vikram B Wali¹, Richard Lifton¹, Lajos Pusztai¹ and Christos Hatzis¹. ¹Yale University, New Haven, CT and ²MD Anderson Cancer Center, Houston, TX.

Body: Purpose: Previous efforts to develop transcriptional markers of chemotherapy sensitivity in TNBC had limited success due to the heterogeneity of this disease. The purpose of this study was to identify genomic differences between extremely chemotherapy sensitive and highly chemotherapy resistant TNBC through whole exome sequencing and to assess measures of genomic heterogeneity as predictive markers.

Methods: Twenty nine cases were selected from a prospectively collected cohort of fine needle aspiration specimens obtained before preoperative chemotherapy (MDACC) to represent two extreme response cohorts including pathologic complete response (pCR, N=17) or extensive residual cancer (eRD, N=12). DNA was extracted from specimens stored in RNAlater, exomes were captured using NimbleGen SeqCap EZ Exome Library preparation and paired-end sequencing of 75 base pair fragments was performed on Illumina HiSeq 2000. Alignment and variant calling were performed with BWA and GATK haplotype caller. Variants were filtered against the 1000 Genomes and TCGA normal breast samples to identify candidate somatic variants. Fisher-exact test was used to identify variant genes associated with sensitivity to chemotherapy. We calculated overall mutational load and normal-adjusted clonal entropy of driver mutations as measures of genome heterogeneity. The chi-squared test was used to compare differences in mutational spectra and genome heterogeneity between the two response groups.

Results: The mean coverage was over 150X and 93% of target regions had > 20X coverage. The number of non-silent COSMIC mutations was similar in tumors from the two response groups (pCR: 63, range 49-82; eRD: 59, range 43-78) as well as the number of novel non-silent mutations (eRD: 223, range 113-388; pCR: 192, range 125-293). Gene level aggregation of variants identified 4 genes (MUC21, SLCO5A1, LRBA, STNE1) with response-associated mutational patterns. However, mutations were non recurrent and p-values were modest, ranging from 0.04 to 0.005. We observed greater overall mutational load and subclonal heterogeneity (clonal entropy of cancer related mutations) associated with eRD compared to pCR. Both measures suggest that higher genomic DNA diversity is associated with chemotherapy resistance. However, some genes (BRCA1 and MKI67) had higher mutational load (sum of minor allele frequencies per gene) associated with pCR compared to eRD. In general, a higher proportion of C>T transition (P=0.011) and lower A>G transition (P=0.028) was associated with eRD. The same mutational spectrum shift was previously described in the comparison of trunk and branch driver events suggesting that eRD tumors may undergo heterogeneous branched evolution.

Conclusion: We observed greater genomic diversity and distinctive mutational spectra in original pre-treatment samples of TNBC that were associated with extensive residual disease compared to pCR. Our analysis suggests that broad measures of genomic diversity may serve as markers of resistance to chemotherapy.

Title: Impact of neoadjuvant chemotherapy on the clonal composition of breast cancer

Matthew P Goetz¹, Michael T Barrett², Krishna R Kalari¹, Vera J Suman¹, Sarah A McLaughlin³, Alvaro Moreno-Aspitia³, Ann M Moyer¹, Donald W Northfelt², Richard J Gray², Jason Sinnwell¹, Douglas Mahoney¹, Poulami Barman¹, Peter Vedell¹, Xiaojia Tang¹, Kevin Thompson¹, Travis Dockter¹, Katie Jones¹, Sara J Felten¹, Amy Conners¹, Jeanette Eckel-Passow¹, Hughes Sicotte¹, Steven N Hart¹, Jia Yu¹, Daniel W Visscher¹, Eric D Wieben¹, Cloann Schultz¹, Minetta C Liu¹, James N Ingle¹, Liewei Wang¹, Richard W Weinshilboum¹ and Judy C Boughey¹. ¹Mayo Clinic, Rochester, MN; ²Mayo Clinic, Scottsdale, AZ and ³Mayo Clinic, Jacksonville, FL.

Body: Background
Cancer genomic investigations have identified recurrent genomic aberrations critical for cancer initiation, progression, and metastases. However, these investigations are typically performed in isolation, and the effects of treatment on the clonal selection of tumor cells are mostly unknown. We hypothesized that molecular profiling of residual tumors after neoadjuvant chemotherapy (NAC) would identify new drug targets/pathways in patients at high risk for disease recurrence. To better identify clonal populations of resistant breast cancer cells, we utilized DNA content-based flow sorting of nuclei to identify and isolate clonal populations for aCGH and next generation sequencing (NGS) both before and after NAC.

Methods
The Breast Cancer Genome Guided Therapy Study (BEAUTY) (NCT 02022202) is a prospective study of patients with high-risk breast cancer treated with neoadjuvant 12 weekly paclitaxel (T) +/- trastuzumab followed by 4 cycles of anthracycline based chemotherapy. Tumor tissue from baseline, residual disease from surgery, distant metastases, and patient derived xenografts (PDX) are obtained for cell sorting by DNA ploidy, aCGH, RNA and exome sequencing.

Results: 140 patients have been enrolled, 104 have completed surgery and 30 unique PDX have been established corresponding to 26 patients prior to chemotherapy and 4 from residual disease at surgery. Baseline exome and RNA sequencing is complete in 140. Currently, genomic analyses of flow sorted matched baseline, surgical, PDX, and distant disease samples are available in 6 patients. Substantial genomic variation was observed in the surgical sample compared to the primary tumor including gain of oncogenic drivers (EGFR) and loss of negative regulators (ATG5) (Table). The PDX recapitulated these events with excellent fidelity compared to the corresponding human tumor. In patients with TNBC, RNA seq obtained from matched samples demonstrated changes in immune related pathways. Evaluation of drug targets/pathways identified in the resistant tumors are ongoing using the PDX and sequencing of the remaining matched baseline/surgical disease will be reported.

Conclusions: We observed substantial evolutionary changes in residual breast tumors remaining after NAC. Our findings suggest that a comprehensive assessment of the mutational landscape that has evolved during NAC can inform drug development in high risk breast cancer patients.
Title: Reliability of whole exome sequencing for assessing intratumor heterogeneity from breast tumor biopsies

Weiwei Shi¹, Anees Chagpar¹, Tingting Jiang¹, Donald R Lannin¹, Brigid Killelea¹, Nina Horowitz¹, Raymond Lim², James Platt¹, Charlotte KY Ng², Vikram B Wali¹, Britta Weigelt², Jorge S Reis-Filho², Christos Hatzis¹ and Lajos Pusztai¹. ¹Yale University, New Haven, CT and ²Memorial Sloan Kettering Cancer Center, New York, NY.

Body: BACKGROUND: False positive findings introduced by analytical noise in sequencing and bioinformatics pipelines constitute a challenge for accurate massively parallel sequencing (MPS). Reports of intratumor genomic heterogeneity based on MPS rarely estimate the impact of false positive mutation calls. The purpose of this study was to measure apparent genomic heterogeneity in different regions of the same tumor and to assess the technical noise in variant calling in replicate sequencing of the same DNA.

METHODS: Three anatomically distinct biopsies were obtained from 3 different regions of 11 breast cancers (33 samples) including 6 low/intermediate grade, estrogen receptor (ER)-positive and 5 high-grade, triple-negative (TNBC) cancers. DNA from 8 different biopsies was split and independently processed on different days to obtain technical replicates. The NimbleGen SeqCap EZ Exome Library preparation method was used for exome capture and paired-end sequencing of 75 base pair fragments was performed on Illumina HiSeq 2000. Read alignment and variant calling were performed with BWA and GATK haplotype caller. Concordance in variant calls and in minor allele frequencies (MAF) was assessed in the 3 biopsies of the same tumor and 8 technical replicates. We adjusted for uneven sequence coverage and analyzed known germline variants from dbSNP, known cancer related variants from COSMIC separately from novel variants (i.e. not previously reported in dbSNP or COSMIC). We estimated intratumor genomic heterogeneity of genes after removing alterations identified in areas where mapping is difficult and variant calls that had low analytical reliability in the technical replicates.

RESULTS: The mean coverage was over 150X and > 90% of target regions had ≥ 20X coverage. We validated the specificity (98.2%) and sensitivity (86.7%) of the variant calling pipeline on the GIAB reference data. The concordance for germ line SNPs and variants in COSMIC in technical replicates was 94.9% and 92.7%, respectively. Novel variants had very low concordance, 55.9%, in technical replicates. The concordance between MAF estimates from the technical replicates was high (0.974, 0.957 and 0.969 for single nucleotide variations, insertions and deletions, respectively). The concordance for germline SNPs and COSMIC variants in pairwise comparisons of biopsies from the same tumor was 93.2% and 91.1%. For known variants, lower concordance was observed in TNBC (88.3%-98.5%) compared to ER-positive tumors (93.6%-98.8%, P<0.05) indicating greater intratumor heterogeneity. We identified variants in a small number of genes (DNAH9, PPM1E, and MAP3K1) that were called inconsistently in most technical replicates, even after excluding low mappability regions. We assessed intratumor heterogeneity in the triplicate biopsies, after excluding the technically unreliable variants. On average, two different biopsies from the same tumor shared 14272 +/− 1379 common variants and differed in 816 +/− 416 variants.

CONCLUSION: We observed heterogeneity to be slightly greater in high-grade, ER-negative compared to low-grade, ER-positive breast cancers. Differences in variants observed in multiple biopsies of the same tumor are only slightly greater than those expected by technical noise alone.
Title: Whole exome sequencing (WES) of HER2+ metastatic breast cancer (MBC) from patients with or without prior trastuzumab (T): A correlative analysis of TBCRC003

Nikhil Wagle¹, Nancy U Lin¹, Andrea L Richardson³, Ignaty Leshchiner², Ingrid A Mayer⁴, Andres Forero-Torres⁵, Timothy J Hobday⁶, Elizabeth C Dees⁷, Rita Nanda⁸, Mothaffar F Rimawi⁹, Hao Guo¹, William T Barry¹, Ron Bose¹¹, Wei Shen¹¹, Antonio C Wolff¹⁰, Stacey B Gabriel², Levi A Garraway¹, Eric P Winer¹ and Ian E Krop¹.

¹Dana-Farber Cancer Institute, Boston, MA; ²Broad Institute, Cambridge, MA; ³Brigham and Women’s Hospital, Boston, MA; ⁴Vanderbilt-Ingram Cancer Center, Nashville, TN; ⁵University of Alabama, Birmingham, AL; ⁶Mayo Clinic, Rochester, MN; ⁷UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC; ⁸University of Chicago, Chicago, IL; ⁹Baylor College of Medicine, Houston, TX; ¹⁰Johns Hopkins Hospital, Baltimore, MD and ¹¹Washington University School of Medicine, St Louis, MO.

Body: Background: Although the spectrum of genomic alterations in primary, treatment-naïve breast tumors has been described, the genomic landscape of HER2+ MBC remains underexplored. Furthermore, tumor genomic alterations that arise after progression on anti-HER2 therapy are largely unknown.

Methods: We prospectively collected metastatic tumor biopsies from patients (pts) enrolled on TBCRC003 (NCT00470704), a phase II study evaluating the combination of lapatinib (L) and T in pts with HER2+ MBC who had varying degrees of prior T exposure. We performed WES on baseline metastatic biopsies and normal DNA from 57 pts. In 36 pts, we also performed WES on pre-treatment primary tumors. Tumors were analyzed for point mutations, insertions/deletions, and copy number alterations.

Results: Total accrual was 116 pts. 87 pts were registered in one of two efficacy cohorts: Cohort 1 included pts w no prior T for MBC. Pts with prior adjuvant T were included if the interval from last T to 1st recurrence > 12 months. Cohort 2 included pts with 1-2 prior lines of T for MBC or recurrence within 12 months of adjuvant T. An additional 29 pts were enrolled in a biomarker cohort (Cohort 3). Per-protocol efficacy analyses for 85 pts deemed evaluable are shown below:

<table>

</tbody>
</table>

As we previously reported (Wagle et al, ASCO 2014), across 57 metastatic tumors, significant recurrently mutated genes were TP53 (n=30; 53%) and PIK3CA (n=19; 33%). The frequency of mutant TP53 and PIK3CA was not significantly different from 119 primary, treatment-naïve HER2+ tumors sequenced in the TCGA study (50%, p=0.8 and 27%, p=0.5, respectively). Recurrent copy number alterations were also similar to TCGA data. Comparing the 38 pts who received any prior T with the 19 pts who did not, there was no significant difference in the incidence of mutant TP53 (53% vs 53%, p=1.0) and PIK3CA (37% vs 26%, p=0.6).

We identified mutations in the HER2 kinase domain in 4/38 pts who received prior T (11%), as compared to 0/19 T-naïve pts. HER2 kinase domain mutations have been identified in ~2% of HER2-negative cancers but <1% of primary HER2+ cancers. 3 of the mutations were L755S, which has been shown to be resistant to L and sensitive to irreversible HER2 inhibitors. The 4th mutation was D742N, a novel kinase domain mutation. None of the 4 pts with HER2 kinase domain mutations had an objective response, though 1 pt had stable disease for 29 weeks.

An analysis comparing paired archival primary tumors and baseline metastatic biopsies from 36 pts to identify genomic alterations acquired or enriched in the metastatic tumors will be presented.

Conclusions: We present an analysis of the genomic landscape of HER2+ MBC, including comparisons between matched primary tumors and metastatic biopsies. Somatic HER2 kinase mutations in pts with HER2+ MBC treated with prior T suggests...
that these mutations may be involved in resistance to T, and may predict poor response to additional anti-HER2 therapy with combined L and T. Novel therapeutic approaches may be required for these pts.

Title: ConvertHER: Evolution of genomic alterations from primary to metastatic breast cancer

Ana Maria Gonzalez-Angulo¹, Ana Lluch², Agda K Eterovic¹, Angel Guerrero³, Xiaofeng Zheng¹, Ramon Perez⁴, Shuying Liu¹, José I Chacón⁵, Ken Chen¹, Silvia Antolin⁶, Gordon B Mills¹, Jaime Ferrer², Octavio Burgues², Begona Bermejo⁷, Elia Munoz⁷, Rosalia Caballero⁸, Eva Carrasco⁸, Eduardo Martinez⁹ and Funda Meric-Bernstam¹. ¹University of Texas MD Anderson Cancer Center; ²INCLIVA BioMedical Research Institute, Hospital Clínico de Valencia; ³Instituto Valenciano de Oncología; ⁴Clínica Quirón; ⁵Hospital Virgen de la Salud; ⁶Complejo Hospitalario Universitario A Coruña, A Coruña, Spain; ⁷Hospital de La Plana; ⁸GEICAM, San Sebastián de los Reyes and ⁹Hospital Provincial de Castellón.

Body: Background: Changes in breast cancer receptor status over disease progression and treatment have been described to a point that could alter response to therapy. There is growing interest in delivering biomarker/genomically-based targeted therapies. We aimed to determine the concordance of genomic alterations between primary (P) and metastatic (M) breast cancer in a prospective collection study.

Methods: Targeted capture and next-generation sequencing was performed on formalin-fixed paraffin-embedded (FFPE) samples, profiling 202 cancer relevant genes in 61 pairs (primary and corresponding recurrence/metastasis). Tumors were classified at baseline as [hormone receptor (HR)+/HER2-, HR+/HER2+, HER-/HER2+, and triple negative breast cancer (TNBC)]. We aligned data to human reference assembly hg19 using Burrows-Wheeler Aligner’s (BWA) and removed duplicated reads. We identified somatic mutations variants and called copy number alterations (CNA) using an algorithm which reports gain or loss status of each exon. Alterations potentially targetable with established or investigational therapeutics were considered “actionable.”

Results: Of the 61 cases, 15% changed breast cancer subtype. Of 747 mutations detected in 156 genes, 309 (41%) were discordant. Median number of mutations were 10 (range 6-11) in P and 8 (range 6-10) in M. Most common mutations occurred at NOTCH2, PCLO, MAP3K1, MLL3, NOTCH4, CRIPAK, TP53, PIK3CA, and FLG. Mutations were less common in HR-/HER2+ tumors in both P and M. Mutation discordance was not different in cases of changed breast cancer subtype (P=.31). Of 986 CNA detected in 173 genes, 758 (77%) were discordant. There was an increased frequency of EGFR1, ERBB2, FGFR3, CRIPAK, MEN1 and WT1 amplifications in M. CNA were less common in HR-/HER2+ tumors in both P and M. CNA discordances were more common in cases of changed breast cancer subtype (P<.0001) and driven by HER2- tumors. Fifty-eight (95%) patients had actionable alterations that could inform targeted treatment options.

Conclusion: Deep targeted exome sequencing of cancer-related genes revealed potentially targeted alterations. We found 41% and 77% mutation and CNA discordance between P and M. CNA were more common when breast cancer subtype changed.
Title: Plasma circulating tumor DNA as an alternative to metastatic biopsies for mutational analyses in breast cancer

Michail Ignatiadis¹, Française Rothe¹, Jean-François Laes², Diether Lambrechts³⁴, Dominiek Smeets³⁴, Delphine Vincent¹, Marion Maetens¹, Debora Fumagalli¹, Stefan Michiels⁵, Stylianos Drisis¹, Carine Moerman¹, Jean-Pol Detiffe², Denis Larsimont¹, Ahmad Awada¹, Martine Piccart¹ and Christos Sotiriou¹. ¹Institut Jules Bordet, Université Libre de Bruxelles, Belgium; ²OncoDNA, Gosselies, Belgium; ³Katholieke Universiteit Leuven, Belgium; ⁴Vesalius Research Center, VIB, Belgium and ⁵Gustave Roussy, Univ. Paris-Sud, France.

Body: Background: Molecular screening programs are using next-generation sequencing (NGS) for cancer gene panels in metastatic biopsies. We interrogated whether plasma can be used as an alternative to metastatic biopsies.

Patients and methods: The Ion AmpliSeqTM Cancer Hotspot Panel v2 (Ion Torrent), covering approximately 2,800 COSMIC mutations from 50 cancer genes was used to analyze 70 primary and/or metastases and 29 plasma samples from 17 metastatic breast cancer patients. The targeted coverage for tissue DNA was 1000x and for plasma circulating DNA 25000x. Whole blood normal DNA was used to exclude germline variants. The Illumina technology was used for independent validation.

Results: Twelve patients had estrogen receptor (ER)+/ human epidermal growth factor receptor 2 (HER2)-, 1 ER+/HER2+, 2 ER-/HER2+ and 2 ER-/HER2- tumors. Evaluable NGS results were obtained for 61 primary/metastases and 29 plasma samples from 17 patients. When primary/metastases were analyzed, 12 of 17 patients had at least 1 mutation (median 1 mutation per patient, range 0-2) in either p53, PIK3CA, PTEN, AKT1 or IDH2 gene. When plasma was analyzed, 11 of 17 patients had at least 1 mutation (median 1 mutation per patient, range 0-2) in either p53, PIK3CA, PTEN, AKT1, IDH2 and SMAD4. All primary/metastases/plasma mutations were independently validated using the illumina technology. When we focused on metastases and plasma samples collected at the same time point, we observed that in 4 patients, no mutation was identified in either metastases or plasma, in 9 patients the same mutations were identified in metastases and plasma, in 2 patients a mutation was identified in metastases but not in plasma and in 2 patients a mutation was identified in plasma but not in metastases (Table1). Thus, in 13 of 17 (76%) patients, metastases and plasma analysis provided concordant results whereas in 4 of 17 (24%) demonstrate discordant results providing complementary information (Table1). Conclusion: Plasma can be tested as an alternative tissue source in molecular screening programs.

Title: Circulating tumor DNA and circulating tumor cells in metastatic triple negative breast cancer patients

Francois-Clement Bidard, Jordan Madic, Anna Kiialainen, Fabian Birzele, Guillemette Ramey, Quentin Leroy, Thomas Rio Frio, Virginie Raynal, Virginie Bernard, Alban Lermine, Inga Clausen, Nicolas Giroud, Roland Schmucki, Carsten Horn, Olivia Spleiss, Olivier Lantz, Marc-Henri Stern, Martin Weisser, Ronald Lebofsky and Jean-Yves Pierga. 1Institut Curie, Paris, France; 2Roche Pharma Research and Early Development (pRED), Innovation Center, Basel, Switzerland; 3Institut Roche de Recherche et Médecine Translationnelle, Boulogne-Billancourt, France and 4Roche Pharma Research and Early Development (pRED), Innovation Center, Penzberg, Germany.

Body: Background
Preliminary reports suggested that circulating tumor DNA (ctDNA) can be used as a prognostic marker in a way akin to circulating tumor cells (CTC) in metastatic breast cancer patients. However ctDNA detection is often performed on multiple mutations, combining heterogeneous techniques. Here we used the high prevalence of TP53 mutations in triple-negative metastatic breast cancer (TNMBC) to compare CTC and ctDNA detection rates and prognostic value.

Methods
A cohort of 40 patients treated at the Institut Curie (Paris, France) was enrolled before starting a new line of treatment for TNMBC. CTC were detected by the CellSearch system (in 7.5 mL of blood). Using massively parallel sequencing (NGS), TP53 mutations were first characterized in tumor tissue, then in plasma DNA extracted from fresh frozen plasma samples (from 15-20 mL of blood). ctDNA detection was performed using high depth targeted sequencing using two platforms in parallel (Illumina HiSeq 2500 and Roche 454). Libraries for Illumina were prepared following the TAm-Seq procedure (Forshew et al, Sci Transl Med 2012), with preamplification of all coding TP53 exons and flanking untranslated regions followed by both paired-end 150bp Illumina and 454/Roche sequencing. CTC, ctDNA and usual patient characteristics were correlated with time to progression (TTP) and overall survival (OS).

Results
Archived tumor (FFPE or frozen) tissue was available for 36 patients, and 31 were successfully sequenced: TP53 mutations were found in 27 patients. As measured on the Illumina platform, ctDNA was detected in 21/27 patients (81%), ranging from 48 to 648,000 copies/mL of plasma (median 1620). Mutant allele fraction in circulating cell-free DNA ranged from 2 to 70% (median 5%). Comparison between ctDNA levels measured by Illumina and 454/Roche platforms in plasma displayed a good correlation (R² = 0.903), with a single discordance. ≥1 CTC were detected in 19 of these 27 patients (70%). Strikingly, high ctDNA levels had prognostic impact neither on OS, nor on TTP, whatever the dataset used (Illumina or 454) whereas CTC≥5/7.5 mL were correlated with OS (p=0.04) and marginally with TTP (p=0.06). Other known usual factors, such as poor performance status, elevated LDH and number of previous treatment lines had also significant prognostic factors in this cohort. CTC and ctDNA early changes during treatment were available for 12 patients and changes (increase/decrease) of the two biomarkers were globally similar.

Conclusion
Demonstrating a good sensitivity (81%), ctDNA by the TAm-Seq is more frequently detected than CTCs in the 27 TNMBC with TP53 mutations. The observed correlation between the 2 massively parallel sequencing approaches suggested that ctDNA levels data were quantitative. In contrast to other usual prognostic factors, baseline ctDNA level did not demonstrate a prognostic impact, in this proof-of-principle study, suggesting that mechanisms of ctDNA release in TNMBC rely on biological features that do not dramatically impact patient’s outcome.

Title: Timing, severity and risk factors for arthralgia in the IBIS-II trial: A retrospective and exploratory analysis

Ivana Sestak¹, Anthony Howell², John F Forbes³, Patrick Neven⁴ and Jack Cuzick¹. ¹Centre for Cancer Prevention, Queen Mary University, London, United Kingdom; ²Institute of Cancer Sciences, University of Manchester, Manchester, United Kingdom; ³School of Medicine and Public Health, University of Newcastle, Newcastle, Australia and ⁴UZ Leuven, Leuven, Belgium.

Body: Background: Arthralgia is a well known side effect of aromatase inhibitors and low oestrogen levels and postmenopausal status are associated with this event. Anastrozole reduced the incidence of oestrogen receptor positive, invasive breast cancer by 58% in the IBIS-II trial. However, timing, severity and risk factors for arthralgia have not been assessed in detail in this trial.

Methods: The IBIS-II trial randomised postmenopausal women at high risk to receive 1mg anastrozole or matching placebo for 5 years. Date of occurrence of arthralgia along with severity (mild, moderate, severe) were recorded at each yearly follow-up visit. Age, body mass index (BMI), and previous hormone replacement therapy (HRT) were investigated as potential risk factors for arthralgia. All analyses were done by the use of logistic regression.

Results: 3864 postmenopausal women (anastrozole: 1920, placebo: 1944) were enrolled in the IBIS-II trial. 58.5% of women randomised to anastrozole reported arthralgia at any time during the trial compared with 52.8% on placebo (OR=1.26 (1.11-1.43), P=0.0004). The majority of arthralgias were reported within the first 18 months of randomisation, with a decline thereafter (Table). 17.5% of women who reported arthralgia withdrew from the trial compared to 13.9% without any of these symptoms (OR=1.31 (1.10-1.57)), and the withdrawal was significantly greater for those with severe symptoms compared to mild (OR=5.97 (4.27-8.33)). Women who used HRT before trial entry had a significant higher risk of developing arthralgia than their counterparts irrespective of allocated treatment (OR=1.45 (1.27-1.64), P<0.001). Increasing BMI (lowest vs. highest BMI group: OR=1.30 (1.11-1.53)) and age (lowest vs. highest age group: OR=1.23 (1.01-1.50)) were also significant risk factors for arthralgia. HRT and BMI remained highly significant in a multivariate model.

Conclusion: Arthralgia was common in the IBIS-II trial irrespective of treatment. However it increased in severity in the active treatment arm mainly in the 18 month period after randomisation. Severe arthralgia led to significantly more withdrawals from the trial than mild symptoms irrespective of treatment. Major risk factors for arthralgia in both arms were previous HRT use and obesity.

Title: Cardiovascular toxicity following aromatase inhibitor use in 13,273 survivors cared for in a HMO

Reina Haque¹, Joanne E Schottinger¹, Jiaxiao Shi¹, Joanie Chung¹, Chantal Avila¹, Britta Amundsen¹ and Rowan T Chlebowski².
¹Kaiser Permanente Southern California, Pasadena, CA and ²Los Angeles BioMedical Research Institute at the Harbor-UCLA Medical Center, Torrance, CA.

Body: Background
Aromatase inhibitors (AIs) reduce breast cancer incidence in primary prevention trials (MAP3, IBIS2). However, controversy regarding AI's influence on cardiovascular disease (MI, angina, and cardiac failure) (Amir et al JNCI 2011) could limit use in prevention settings.

Methods
We assembled a cohort of 13,273 postmenopausal breast cancer patients initially CVD (cardiovascular disease)-free at diagnosis in a large managed care organization. Women were diagnosed 1991-2010, and followed through 2012. The outcome, CVD risk was compared across endocrine treatments (AI, tamoxifen [TAM], both, or neither). Information on demographics, comorbidity (diabetes, hypertension, etc.), and covariate medications (antihyperlipidemics, antihypertensives, and other CVD drugs) were available from electronic medical records. We conducted Cox models using time-dependent endocrine drug use variables adjusted for age, demographics, comorbidity, and CVD drug use, cancer treatment, tumor characteristics and tumor laterality.

Results
Among the 13,273 cohort, postmenopausal women who used AIs exclusively had a similar risk of ischemic disease (HR=0.97, 95% CI: 0.78-1.22) and stroke (HR=0.97, 95% CI: 0.70-1.33) versus those who used TAM only (HR=1.00, reference). However, women who used AIs only had a higher risk of other CVD disease combined (CHF, cardiomyopathy, dysrhythmia, valvular dysfunction, pericarditis) (HR=1.26, 95% CI: 1.11-1.43) than those exposed to TAM only. The risk of other CVD disease was greater among women exposed to sequential TAM and AI treatment. The results are based on 3,711 CVD events occurring in 72,886 woman-years of follow-up.

</table>

Based on a subset of 7,982 patients who underwent breast irradiation, the risk of CVD overall was greater among women who used AIs only and received left-sided irradiation (HR=1.21, 95% CI: 1.02-1.44).

</table>
Discussion
These results indicate that variation exists in the type of CVD events that occur in breast cancer patients receiving AIs in comparison to tamoxifen users. For example, the risk of ischemic disease or stroke was not elevated in those who used AIs only versus TAM users. However, overall CVD events were greater in women who used AIs only (or sequentially after TAM), especially if they received left-sided breast irradiation. While these observational study results require cautious interpretation, they provide a basis for comparing the benefits and risks of endocrine treatments.
Title: Prevalence, health care utilization and costs of concomitant depression among breast cancer survivors

Diana D Jeffery1. 1Defense Health Agency, Healthcare Operations Directorate, Clinical Support Division, Falls Church, VA.

Body: Purpose: Concomitant conditions in a cohort of non-elderly breast cancer survivors (BCS) were examined with a focus on the prevalence, healthcare utilization, and costs of diagnosed depression. Little research has been conducted on how concomitant depression among cancer survivors impacts utilization and costs of care.

Methods: Using administrative claims data from the Military Health System Data Repository (MHSDR), a cohort of 2,851 BCS was identified with at least 2 years survival from the time of diagnosis. Concomitant conditions were based on ICD-9 codes; codes 296.2, 296.3, 298.0, and 311 were used to identify depression. Fiscal year 2009 was used as the index year to calculate healthcare utilization and costs. Bivariate analyses and logistic regression analysis were used to examine group differences and predictors of having received a diagnosis of depression.

Findings. The most common concomitant chronic conditions in the BCS cohort were hypertension (50.0%), mood disorders or adjustment disorders (37.5%), heart disease (23.0%), diabetes (19.9%), history of tobacco use (19.7%), asthma or chronic obstructive pulmonary disease (16%), and obesity (16.8%). About 15.9% of the BCS were diagnosed with depression in the year prior to, at the time of, or in the 2-year follow up period after the cancer diagnosis. With bivariate analysis, significant differences were found between BCS with and without depression: those with depression had higher mean number of hospital stays (.33 vs .11), mean number of bed days (1.94 vs .58), mean number of ambulatory visits (34.26 vs 20.42), and mean number of pharmacy prescriptions (45.49 vs 27.60). For follow up care, BCS with a diagnosis of depression cost, on average, $7174 more annually then those without a diagnosis of depression ($15,471 vs $8,297). No demographic characteristics significantly increased the likelihood of having received a diagnosis of depression.

Discussion. The results show much higher annual health care utilization and costs for BCS diagnosed with depression compared to BCS without a diagnosis of depression. These findings may reflect the health care plan provided to military-related beneficiaries, a plan that has few restrictions for cancer follow up care if medically ordered. Claims data contains no information about cancer stage, a correlate of health care utilization and costs. Overall, the findings provide empirical evidence that there is a fiscal incentive to screen and manage mild symptoms prior to patients meeting diagnostic criteria for clinical depression. Assumedly, timely screening and rapid intervention will lead to improved quality of life for the patient, decreased utilization of health care resources, and cost savings for health care plans. In this respect, the findings support the 2014 ASCO recommendations regarding screening and treatment for depression and anxiety. Conversely, the data intimate that adoption of the ASCO recommendations will lead to higher costs as more individuals are positively screened and referred for treatment. Who, what, or how such services will be afforded merits sustained inquiry.

Title: Blood draws, injections, blood pressure readings in the at-risk arm, and flying might not be associated with increases in arm volume: A prospective study

Chantal M Ferguson¹, Cynthia L Miller¹, Nora Horick², Melissa N Skolny¹, Meyha N Swaroop¹, Lauren S Jammallo¹, Jean A O'Toole³, Michelle C Specht⁴ and Alphonse G Taghian¹. ¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Massachusetts General Hospital, Boston, MA and ⁴Massachusetts General Hospital, Boston, MA.

Body: Introduction:
Breast cancer related lymphedema (BCRL) is a swelling caused by compromise of the lymphatic system after breast cancer treatment. Commonly-cited risk factors include treatment related variables such as axillary lymph node dissection (ALND) and regional lymph node radiation (RLNR), and patient characteristics including BMI. Patients are often advised to avoid blood draws, injections, and blood pressure cuffs on their at-risk arm, airplane travel, and extensive exercise to reduce the risk of developing BCRL; however, data demonstrating the efficacy of such avoidance strategies do not exist. We sought to determine the impact of blood draws, injections, and blood pressure readings in the at-risk arm, and flying on increases in arm volume in a large, prospective cohort of patients.

Methods:
522 patients who underwent treatment for unilateral breast cancer between were included. Patients were prospectively screened for BCRL with Perometer arm measurements pre-operatively, post-operatively, and at 3-8 month intervals thereafter. At each measurement patients were asked to report number of blood draws, injections, and blood pressure readings in the at-risk arm, and number of flights since the last measurement, and their responses were assessed for association with relative volume change (RVC). RVC was analyzed as a continuous variable for association with risk factors.

Results:
522 patients with 2033 post operative measurements were included. Patients were followed for a median of 23 months and 4 post-operative measurements, with a minimum of 1 post-operative measurement and a maximum of 14. 5.56%. 76.8% (401/522) underwent lumpectomy, 23.2% (121/522) underwent mastectomy. 70% (366/522) underwent sentinel lymph node biopsy, and 19% (98/522) underwent ALND. 62.4% (352/521) received radiation to the breast/ chest wall only, and 21.5% (112/521) also received regional lymph node radiation. By univariate analysis, there was no significant association between RVC increase and undergoing one or more blood draws (p=0.36), blood pressure (p=0.88), injections (p=0.79), or number of flights (p=0.89). ALND was significantly associated with increases in arm volume (p=0.0017) by univariate analysis and older age at diagnosis was associated with increased RVC with borderline significance (p=0.059).

Conclusions:
In our patient population, non-treatment related risk factors including blood draws, blood pressures, and injections in the at-risk arm, and flying were not significantly associated with increases in arm volume. This data can be used to help improve and refine patient education regarding the importance of risk-reducing practices after breast cancer treatment.
Title: Characteristics associated with nonadherence to medications for hypertension, diabetes, and dyslipidemias among breast cancer survivors

Gregory S Calip,1,2 and Denise M Boudreau2,3,4. 1University of Illinois at Chicago, Center for Pharmacoepidemiology and Pharmacoeconomic Research, Chicago, IL; 2University of Washington, Seattle, WA; 3University of Washington, School of Pharmacy, Seattle, WA and 4Group Health Research Institute, Seattle, WA.

Body: Background: Comorbidity among breast cancer (BC) survivors increases risk of overall mortality and recent reports have described some comorbid conditions to possibly influence risk of second BC events and BC-specific mortality. Therefore, clinical management of chronic conditions such as hypertension (HTN), diabetes mellitus (DM) and dyslipidemias in BC survivors may be important to both cancer- and non-cancer-related outcomes. Medication adherence for chronic conditions such as diabetes is poor in general populations and quality of care may be further impacted by BC diagnosis/treatment. The objective of this study was to describe characteristics associated with nonadherence to medications to treat HTN, DM and dyslipidemias among BC survivors enrolled in a large, integrated health plan.

Methods: Retrospective cohort of 4,216 BC survivors, the Commonly Used Medications and Breast Cancer Outcomes (COMBO) study at Group Health Cooperative. Women in our analysis were diagnosed with stages I-II BC between 1990-2008 and alive and without recurrence or second primary BC in the year 365 days post-BC diagnosis (days 366-730). Medication users were identified by ≥1 dispensings of antihypertensives, oral DM medications, and/or statins. Data on incident BC, patient characteristics, and medications was obtained via linkage to the western Washington SEER registry, medical record and automated health plan data including pharmacy dispensing records. Medication adherence was measured using medication possession ratio (MPR) and classified as non-adherent if MPR<0.80. We estimated odds ratios (ORs) and 95% confidence intervals (CIs) for nonadherence vs adherence to antihypertensives, oral DM medications and statins by various characteristics using multivariate logistic regression.

Results: We identified 1,929 prevalent users of antihypertensives (n=1,779), DM medications (n=499) and/or statins (n=1,072). 37% were non-adherent to antihypertensives; 75% were non-adherent to DM medications; 39% were non-adherent to statins. In adjusted models, younger women (ages <50, 50-64) were more likely to be non-adherent to all 3 therapeutic classes compared to older women (ages ≥65). Women who received radiation therapy (OR=1.21 95% CI 1.00-1.47) or endocrine therapy (OR=1.25 95% CI 1.03-1.52) were more likely to be non-adherent to antihypertensives; women treated with chemotherapy (OR=1.67 95% CI 1.03-2.69) were more likely to be non-adherent to DM medications. Greater BMI (P=0.001) and more frequent primary care provider visits (≥2 vs 0-1 only; OR=0.30 95% CI 0.24-0.38) were associated with better adherence to antihypertensives. Likewise, higher Charlson comorbidity scores (≥2 vs <2) were associated with greater adherence to DM medications (OR=0.49 95% CI 0.23-0.83) and statins (OR=0.54 95% CI 0.28-1.02).

Conclusion: In this population-based cohort of BC survivors, nonadherence to medications for HTN, DM, and dyslipidemias was associated with younger age, and impact of specific BC treatments on medication adherence varied by therapeutic indication. Additional research is warranted to target patients in need of medication management as well as to explore patient preferences and provider factors that may influence medication adherence.
A randomized placebo-controlled trial of acupuncture and gabapentin for hot flashes among breast cancer survivors

Jun J Mao¹, Sharon X Xie¹, Marjorie A Bowman², Deborah Bruner³, Susan Q Li¹, Angela DeMichele¹ and John T Farrar¹.
¹Perelman School of Medicine at University of Pennsylvania, Philadelphia, PA; ²Wright State University School of Medicine, Dayton, OH and ³Emory University School of Nursing, Atlanta, GA.

Body: Purpose
Hot flashes are a common and debilitating symptom negatively affecting the quality of life of breast cancer survivors. We sought to compare the short and long term effects of electro-acupuncture (EA) vs. gabapentin for hot flashes among breast cancer survivors.

Patients and Methods
We conducted a randomized controlled trial of EA vs. gabapentin vs. placebos (sham acupuncture [SA] or placebo medication) in women with breast cancer who had completed primary cancer treatments and experienced bothersome hot flashes twice daily or greater. Acupuncturists performed ten EA/SA treatments over eight weeks using a manualized protocol with 2 Hz electro-stimulation delivered by a TENS unit. Acupuncturists administered SA using Streitberger (non-penetrating) needles at non-traditional acupuncture points without electro-stimulation. Gabapentin (900 mg daily) or placebo medication were continued for eight weeks and then weaned off. The primary endpoint was the hot flash composite score measured by the daily diary at the end of the intervention (Week 8). A secondary endpoint, durability of response, was evaluated at Week 24 from randomization. Longitudinal mixed effects models were used to evaluate change in outcomes over time and group differences.

Results
Of 120 randomly assigned patients, the mean age was 52.3, 75% were White, 12.5% were peri-menopausal, and 20%/25%/37.5% had natural/surgically/chemically induced menopause, respectively. By Week 8, significant group differences were observed. Mean reduction in hot flash composite scores was greatest in the EA group, followed by SA and gabapentin, with placebo medication having the lowest reduction in hot flashes (−7.4 vs. −5.9 vs. −5.2 vs. −3.4, p=0.0003). By Week 24 and off treatment, reduction in hot flashes in the EA group persisted whereas the hot flashes in the gabapentin group returned to baseline. The reduction in hot flashes was greatest in the EA group, followed by SA, placebo medication, and gabapentin (−8.5 vs. −6.1 vs. −4.6 vs. −2.8, p=0.0024). No serious adverse events were reported in any groups. The gabapentin group had the highest percentage of participants reporting treatment-related adverse events followed by placebo medication, EA, and SA (48.4% vs. 29.0% vs. 19.3% vs. 3.2%, p=0.004).

Conclusion: Electro-acupuncture was more effective than gabapentin, sham acupuncture, or placebo medication in reducing hot flashes for breast cancer survivors both short term and long term with few side effects. Gabapentin produced significant short term reduction in hot flashes that did not persist off medication and was associated with more side effects.

Clinical Trial Registration: NCT01005108.
**Title:** Results from the phase 2 trial of ridaforolimus, dalotuzumab, and exemestane compared to ridaforolimus and exemestane in advanced breast cancer

Hope S Rugo¹, Olivier Tredan², Jungsil Ro³, Serafin Morales⁴, Antonino Musolino⁵, Noemia Afonso⁶, Marta Ferreira⁷, Kyong Hwa Park⁸, Javier Cortes⁹, Antoinette R Tan¹⁰, Joanne L Blum¹¹, Lamar Eaton¹², Christine K Gause¹³, Adelle (Zhen) Wang¹⁴, Ellie Im¹⁵, David J Mauro¹⁶ and José Baselga¹⁶. ¹University of California, San Francisco Medical Center, San Francisco, CA; ²Centre Léon Bérard, Lyon, France; ³National Cancer Center, Goyang-si, Gyeonggi-do, Korea; ⁴Hospital Arnau de Vilanova, Lleida, Spain; ⁵University Hospital of Parma, Parma, Italy; ⁶Instituto Português de Oncologia – Porto, Porto, Portugal; ⁷Instituto Português de Oncologia Francisco Gentil, Porto, Portugal; ⁸Korea University Ansan Hospital, Seoul, Korea; ⁹Vall d’Hebron University Hospital, Institute of Oncology, Barcelona, Spain; ¹⁰Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; ¹¹Baylor Sammons Cancer Center, Dallas, TX; ¹²Merck & Co., Inc, Whitehouse Station, NJ; ¹³Merck Research Laboratories, North Wales, PA; ¹⁴Merck Sharp & Dohme, Beijing, China; ¹⁵Merck & Co., Inc, Kenilworth, NJ and ¹⁶Memorial Sloan Kettering Cancer Center, New York, NY.

**Body:** Introduction: The combination of a mammalian target of rapamycin (mTOR) inhibitor and an aromatase inhibitor has been shown to significantly increase progression-free survival (PFS) in patients with estrogen receptor-positive (ER+) advanced or metastatic breast cancer. Ridaforolimus is an alternative mTOR inhibitor with high potency and specificity. We hypothesized that triplet therapy with ridaforolimus, dalotuzumab (a humanized monoclonal antibody targeting the IGF-1 receptor [IGFR]), and exemestane (R/D/E) would be more effective than doublet therapy with ridaforolimus and exemestane (R/E).

**Methods:** This phase 2, randomized, open-label trial enrolled 80 postmenopausal patients who had high-proliferation (Ki67 staining) ER+ breast cancer that had progressed following treatment with a nonsteroidal aromatase inhibitor. Patients received either triplet therapy, at the previously determined maximum tolerated dose of oral ridaforolimus 10 mg QD×5, dalotuzumab 10 mg/kg/week IV, and oral exemestane 25 mg/day (R/D/E, n=40), or doublet therapy with R 30 mg QD×5 and E 25 mg/day (R/E, n=40). Dose increases of R to 20 or 40 mg QD×5 were permitted in the R/D/E or R/E arms, respectively, in the absence of grade ≥2 stomatitis after cycle 1. The R dose could be reduced in either arm for toxicity. The primary endpoint was PFS in the ITT population by central review. Adverse events (AE) of clinical interest (Tier 1) included stomatitis, pneumonitis, hearing loss, and hyperglycemia.

**Results:** Baseline characteristics were balanced between treatment groups. The median PFS was 23.3 (95% CI, 8.71, 38.43) weeks for R/D/E versus 31.9 (95% CI, 16.00, 39.29) weeks in the R/E arm (hazard ratio, 1.18; 80% CI, 0.81-1.72; P=0.565). All patients experienced at least one AE. 5 (12.8%) and 3 (7.5%) patients in the R/D/E and R/E arms, respectively, discontinued the study because of AE. Serious drug-related AE occurred in 2.6% of the R/D/E arm and 15% of the R/E arm. Dose modifications due to AE occurred in 10.3% and 50% in the R/D/E and R/E arms, respectively (difference -39.7%; 95% CI, -56.7, -20.4). Tier 1 AE were primarily grade 1-2 in severity. Stomatitis occurred in 76.9% (30/39 patients) in the R/D/E arm vs 95.0% (38/40 patients) in the R/E arm (P=0.021), and grade 3-4 stomatitis was similar between arms (23.1% vs 25%). Pneumonitis occurred in 5.1% vs 22.5% (P=0.027) and hearing loss occurred in 1 patient in each treatment arm (2.6% vs 2.5%), all grade 1-2. Hyperglycemia occurred at a similar rate in both treatment arms (28.2% vs 27.5%), with grade 3-4 events in 4 (10.3%) and 3 (7.5%) patients in the R/D/E and R/E arms, respectively.

**Conclusions:** The combination of R 10 mg QD×5, D, and E did not improve PFS when compared to R 30 mg QD×5 plus E. The incidence rates of AE were lower in the R/D/E arm than the R/E arm for most categories of adverse events, likely because of the higher dose of R in the R/E arm. The efficacy reported for R/E in this study is similar to that reported in previous studies evaluating mTOR inhibitors in combination with exemestane in ABC. Overlapping toxicities and lower doses likely contributed to the lack of improved PFS with the addition of the IGFR inhibitor to this combination.
Ph1b study of the PI3K inhibitor taselisib (GDC-0032) in combination with letrozole in patients with hormone receptor-positive advanced breast cancer

Cristina Saura1, Jasgit Sachdev2, Manish R Patel3, Andres Cervantes4, Dejan Juric5, Jeffrey R Infante6, Donald Richards7, Sandra Sanabria1, Xuyang Lu10, Joseph Ware16, Timothy R Wilson16, Hema Parmar10, Jerry Y Hsu16, Mafalda Oliveira1, Eric P Winer8, Daniel D Von Hoff2, Jose Baselga9 and Ian E Krop8.

1Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology Barcelona, Barcelona, Spain; 2Virginia G. Piper Cancer Center/TGen, Scottsdale, AZ; 3Sarah Cannon Research Institute/Florida Cancer Specialists, Sarasota, FL; 4Institute of Health Research INCLIVA, University of Valencia, Valencia, Spain; 5Massachusetts General Hospital Cancer Center, Boston, MA; 6Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN; 7Texas Oncology, Tyler, TX; 8Dana-Farber Cancer Institute, Boston, MA; 9Memorial Sloan Kettering Cancer Center, New York, NY and 10Genentech, San Francisco, CA.

Body: Background: Taselisib (GDC-0032) is a next-generation PI3K inhibitor with increased anti-tumor activity against PIK3CA mutant (MT) cancers. Taselisib is an orally bioavailable, potent, and selective inhibitor of Class I PI3K alpha, delta, and gamma isoforms, with 30-fold less inhibition of the PI3K beta isoform relative to the PI3K alpha isoform. Preclinical data show that taselisib has enhanced activity against PI3K alpha isoform (PIK3CA) MT breast cancer cell lines and enhanced antitumor activity when combined with letrozole. Clinical data with single-agent taselisib also showed increased tumor shrinkage in patients with PIK3CA MT breast cancer as compared to patients with PIK3CA wildtype (WT) breast cancer.

Material and Methods: A Phase 1b dose escalation study was conducted with evaluation of taselisib doses ranging from 6-9 mg QD in combination with letrozole 2.5mg QD in a modified 3+3 design. A dose expansion cohort was conducted with taselisib 6 mg QD. Safety and tolerability of GDC-0032 was assessed, as well as pharmacokinetics (PK), pharmacodynamic (PD) assessment by FDG-PET, and anti-tumor activity by RECIST.

Results: As of 31 January 2014, 28 patients were enrolled onto this study with the completion of dose escalation and the dose expansion cohort. No dose limiting toxicities (DLTs) were observed at either the 6 mg (n = 20) or 9 mg (n = 8) dose levels. Adverse events (AEs) assessed by the investigator as related to taselisib in ≥10% of patients (any grade) included diarrhea, nausea, stomatitis, fatigue, rash, decreased appetite, hyperglycemia, dysgeusia, mucosal inflammation, vomiting, muscle spasms, asthenia, dry mouth, dry skin, pruritus, and aspartate aminotransferase increased. Grade 3 and 4 adverse events assessed by the investigator as drug-related and occurring in greater than one patient included diarrhea (14%), hyperglycemia (7%), and mucosal inflammation (7%). No apparent PK interactions were observed between taselisib and letrozole. The median number of prior systemic therapies was six, and promising efficacy data has been observed in these heavily pretreated patients. Metabolic partial responses via FDG-PET (≥20% decrease in mean SUVmax) were observed in 11 out of 18 patients assessed (61%). Confirmed partial responses by RECIST have been observed at both the 6mg and 9mg taselisib dose levels. For patients with measurable disease at baseline, the overall response rate of 38% was observed in patients with PIK3CA MT breast cancer and 9% in patients with PIK3CA WT breast cancer. Updated data on safety, PD, efficacy, and biomarker correlates will be presented.

Conclusions: The combination of taselisib and letrozole is a well-tolerated regimen with promising preliminary efficacy in PIK3CA MT breast cancer patients. This preliminary Ph1b clinical data is consistent with taselisib preclinical and single-agent clinical data showing increased anti-tumor activity for taselisib in PIK3CA MT breast cancer as compared to PIK3CA WT breast cancer. Taselisib is being further investigated in the neoadjuvant setting in combination with letrozole in the LORELEI study in patients with untreated hormone receptor-positive breast cancer.
Title: Phase I trial: PI3Kα inhibitor BYL719 plus aromatase inhibitor (AI) for patients with hormone receptor-positive (HR+) metastatic breast cancer (MBC)

Payal D Shah1, Mary Ellen Moynahan1, Shanu Modi1, Betty Ann Caravella1, Farrah M Datko2, Stephen Zamora1, Elizabeth Comen1, Theresa Gilewski1, Steven M Sugarman1, Gabriella D’Andrea1, Diana E Lake1, Shari B Goldfarb1, Sujata Patil1, Anne Covey1, Michael F Berger1, Mario E Lacouture1, Larry Norton1, Clifford A Hudis1, Jose Baselga1, Sarat Chandarlapaty1 and Maura N Dickler1. 1Memorial Sloan Kettering Cancer Center, New York, NY and 2Front Range Cancer Specialists, Fort Collins, CO.

Body: Background: Phosphatidylinositol 3-kinase (PI3K) hyperactivation plays a role in endocrine therapy resistance. Adding an α-selective PI3K inhibitor (BYL719) to hormonal therapy may therefore overcome resistance in HR+ MBC. We report results from a phase I study to evaluate the safety and preliminary efficacy of BYL719 plus an AI in patients (pts) with HR+ MBC. Methods: This 3+3 dose-escalation trial studied daily oral BYL719 added to standard dose letrozole (L, Arm A) or exemestane (E, Arm B), and later examined intermittent dosing (Arm C, L + BYL719 every other week; Arm D, E + BYL719 on 5 of 7 days weekly). Pts with HR+ MBC, any/no PIK3CA mutation, and on L/E were eligible. A cycle (C) was 28 days (d). Endpoints were dose-limiting toxicity (DLT), tolerability (CTCAE 4.0), and efficacy (RECIST v1.1). Paired tumor biopsies were performed for genomic and proteomic correlatives. Serial plasma was collected to quantify cell-free (cf) DNA and mutant allele fraction. Results: 14 pts (median (M) age: 55 (30-69) yrs), 7 each on Arms A and B, received a M of 76d (6-312+) of BYL719 + L or E. All were evaluable for toxicity, 10 for response. PIK3CA status was mutant(MT)/wild-type(WT)/unknown in 8/5/1 pts. M number of prior MBC therapies was 2 (1-12) in Arm A, 6 (2-14) in Arm B. Arms had similar toxicities. On Arm A, BYL719 was given at 300mg daily (DL0) to 3 pts who completed the 28d DLT period. 2 pts had 3 distinct DLTs: maculopapular rash (N=1), hyperglycemia (N=1), abdominal pain (N=1). Dose was de-escalated (DL-1=250mg) with no DLT in 3 enrolled pts. On Arm B, DL0, 1 pt experienced DLT (maculopapular rash) of 3 initially enrolled pts. Arm B expansion at DL0 had 1 additional pt with DLT (rash). Clinically significant, treatment-related toxicities included grade (G): none; G3: maculopapular rash (N=8, including 1 pt treated at DL-1), hyperglycemia (N=1) and G1/2: fatigue (N=7), nausea (N=7), and hyperglycemia (N=6). Toxicity required 6 dose reductions in 4pts and discontinuation in 2 pts. M duration on study for PIK3CA MT vs. WT was 169.5d vs. 69.5d, respectively. In pts with PIK3CA-WT MBC evaluable for response (n=7), 6 had clinical benefit: 1 PR (pt heavily pre-treated, including prior L, MBC to liver, Arm A, now C10+ after DLT); SD (n=5, included -29.9%, -19%, -12%), and POD (n=1). In pts with PIK3CA-WT MBC evaluable for response (n=3), 2 had SD (no changes ≥/+5%) and 1 had POD. Serial cfDNA analysis in 4 pts with SD or PR demonstrated a decrease of >90% in the PIK3CA mutant allele fraction on treatment. Due to toxicity seen with continuous BYL719, the study was amended to explore intermittent dosing schedules (Arm C, L; Arm D, E; DL0=250mg), with 5 pts enrolled, 3 of whom have completed the DLT period with no DLTs, and 1 pt with G3 rash. Correlative studies including serial of DNA collection from these pts is ongoing. Conclusions: Continuously dosed BYL719 with L or E shows promising antitumor activity. Skin toxicity warranted evaluation of alternative schedules. Mutant allele fraction may be an early predictor of response and may serve as a pharmacodynamic marker during intermittent treatment. Safety, efficacy, and correlative data from study Arm C and Arm D will also be presented.
**Title:** Phase I study of the PI3Kα inhibitor BYL719 plus fulvestrant in patients with PIK3CA-altered and wild type ER+/HER2- locally advanced or metastatic breast cancer

**Body:**

**Background:**

BYL719 selectively inhibits the α-isoform of Class I PI3K. PI3Kα is encoded by PIK3CA, a frequently altered gene in human cancers. Preclinical data indicate BYL719 may be more effective in patients (pts) with PIK3CA-altered tumors; however there are data to suggest that PIK3CA-wild-type (wt) tumors may also be sensitive to BYL719. Here, we present updated data from the Phase I study of BYL719 + fulvestrant in pts with PIK3CA-altered or -wt ER+/HER2– locally advanced/metastatic breast cancer (BC) (NCT01219699).

**Methods:**

Adult women with PIK3CA-altered (mutation or amplification) ER+/HER2– BC received continuous oral BYL719 (300–400 mg/day; 28-day cycles) + fixed-dose fulvestrant (500 mg every 4 weeks, plus an additional dose 2 weeks after first dose) during dose escalation and expansion. Pts with PIK3CA-wt ER+/HER2– BC were enrolled into the dose expansion to receive BYL719 400 mg/day + fulvestrant. A Bayesian logistic regression model with overdose control guided dose escalation. Primary objective: to determine the maximum tolerated dose (MTD) and/or recommended phase II dose (RP2D) of BYL719 in combination with fulvestrant, which was declared previously as 400 mg/day. An expansion cohort at the MTD assessed safety (CTCAE v4.0), tolerability, pharmacokinetics (PK), and preliminary efficacy (RECIST v1.0).

**Results:**

As of May 2, 2014, 64 pts (PIK3CA-altered n=41; PIK3CA-wt n=16; PIK3CA status unknown/pending n=7) received BYL719 300–400 mg/day + fulvestrant. Median number of prior antineoplastic therapies: 5 (range: 1–12) for pts with PIK3CA-altered tumors and 5 (range: 4–16) for pts with PIK3CA-wt tumors. Prior fulvestrant treatment: 19 (46%) and 7 (44%) pts with PIK3CA-altered and -wt tumors, respectively. Overall, the most common (>25%) adverse events (AEs; all grades/all doses) suspected to be study drug-related were hyperglycemia (41%), diarrhea (34%), nausea (30%), and vomiting (25%). The most common (>10%) study drug-related Grade 3/4 AEs (all doses) were maculopapular rash (14%) and hyperglycemia (13%). Preliminary antitumor activity was observed in this trial. At data cut-off, partial responses (PRs) were observed in 2 patients with PIK3CA-altered tumors evaluable for response (2/33, 6%), but no PRs were observed in the 15 evaluable patients with PIK3CA-wt tumors. Duration of exposure was >16 weeks in 24 (59%) patients with PIK3CA-altered tumors and in 5 (31%) patients with PIK3CA-wt tumors. PK and exposure of BYL719 + fulvestrant was similar to that observed with single-agent BYL719 at the same dose levels. At data cut-off, treatment was ongoing in 20 (49%) and 2 (13%) pts with PIK3CA-altered and -wt tumors, respectively.

**Conclusions:**

BYL719 + fulvestrant demonstrated a favorable safety profile in pts with PIK3CA-altered and -wt ER+/HER2– BC, with mostly on-target effects (i.e. hyperglycemia, rash). Preliminary clinical activity was seen in pts with PIK3CA-altered and -wt tumors, but confirmed PRs were only observed in pts with PIK3CA-altered tumors. The low number of pts with PIK3CA-wt tumors limits further conclusion.
Title: A phase I study of BKM120 and fulvestrant in postmenopausal women with estrogen receptor positive metastatic breast cancer

Cynthia X Ma¹, Jingqin Luo¹, Michael Naughton¹, Foluso Ademuyiwa¹, Rama Suresh¹, Timothy Pluard¹, Gayathri Nagaraj¹, Kaitlin Arnold¹, Craig Lockhart¹ and Matthew J Ellis¹. ¹Washington University School of Medicine, St Louis, MO.

Body: Background
BKM120, an oral pan-Phosphatidylinositol-3-kinase (PI3K) inhibitor, plus fulvestrant (F) induced synergistic anti-tumor effect in preclinical studies of estrogen receptor positive (ER+) breast cancer. We therefore conducted a phase I trial of BKM120 and F in postmenopausal women with ER+ metastatic breast cancer (MBC) to determine the maximum tolerated dose (MTD), tolerability and preliminary efficacy.

Methods
A 3+3 phase I design was chosen for phase IA with BKM120 administered orally to define MTD [Table 1]. Cycle (C) length was 28 days. F 500mg was administered intramuscularly on C1 day (D)1 and D15 then on D1 of each subsequent cycles. Two expansion cohorts, phase IB (intermittent dosing: 5 days on and 2 days off) and Cohort C (continuous dosing: daily) of BKM120 at MTD, was initiated to further assess the tolerability and efficacy. Patients (pts) with ER+ MBC with measurable disease were eligible. No more than 3 lines of systemic therapy in the metastatic setting were allowed in phase 1B or Cohort C. Tumor measurement occurred every 3 cycles. Adverse events (AEs) were assessed by CTCAE 4.0 and response by RECIST 1.1.

Results
Thirty one pts, with median age of 58 (range: 34-71) years, prior exposure to a median of 1 (range: 0-9) endocrine and 0 (range: 0-2) chemo regimens, were enrolled. Majority of pts (83%) had visceral metastasis. Thirty, 25, and 22 pts were evaluable for AE, response and clinical benefit (CB), respectively. Most C1 AEs were grade (G)1 or 2, except 1 G3 diarrhea. No DLT occurred in C1. However, G2/3 AEs required BKM120 interruption and/or reduction in C2 or beyond occurred in 16 (53%) pts, including 9 ALT/AST elevation (G2 10%, G3 17%, G4 3%), 7 rash (G3 23%), and 1 pt each with G2 confusion, G3 hyperglycemia, G2 pneumonitis, and G3 tremor. As of June 3, 2014, 1 pt withdrew consent, 19 pts discontinued therapy due to progressive disease (PD) (n=15) or AE (n=4), 11 pts continue to receive BKM120/F. Fourteen (63.6%, 95% CI: 43.0 - 80.3%) of the 22 evaluable pts derived CB, including 7 partial response (PR) and 7 prolonged stable disease (SD) > 6 months. Archival tumor and circulating tumor DNA are being analyzed for presentation. Data will be updated.

*All occurred in C2+ except the diarrhea, CBR: 63%, NE: Not evaluable, a: off due to AE, b: withdrew consent, # NE for CBR

Conclusion
BKM120 100mg, administered daily or intermittently, plus F was tolerable without DLT during C1. Grade 2/3 AST/ALT and rash were common in both dosing schedules in subsequent cycles resulting in BKM120 interruption/reduction. Promising activity observed in this trial warrants further development of this combination in ER+ BC. Phase III studies are ongoing in pts with ER+ MBC progressed on aromoatase inhibitor.
Title: PTEN and PIK3CA but not p4EBP1 are associated with low rates of pathological complete response (pCR) to trastuzumab based chemotherapy in primary HER2-overexpressing breast cancer

Sibylle Loibl1,9, Silvia Darb-Esfahani2, Alexander Klimowicz3, Gunter von Minckwitz1, Bianca Lederer1, Jens Huober4, Arndt Hartmann5, Holger Eidtmann6, Berit Maria Pfitzner2, Peter A Fasching1, Katharina Tiemann8, Christian Jackisch5, Keyur Mehta1, Michael Untch10 and Carsten Denkert2. 1German Breast Group, Neu-Isenburg, Hessen, Germany; 2Institute of Pathology, Charité – University of Berlin, Berlin, Germany; 3Functional Tissue Imaging Unit, Translational Labs Tom Baker Cancer Centre, Calgary; 4University Hospital, Ulm, Germany; 5University Hospital Erlangen; 6University Hospital Schleswig-Holstein, Campus Kiel; 7University Hospital, Erlangen, Germany; 8University Schleswig-Holstein, Campus Kiel; 9Sana Klinikum Offenbach and 10Helios Klinikum Berlin-Buch.

Body: Background: Phosphatidylinositol 3-kinase (PI3K)/AKT pathway and phosphatase and tensin homolog deleted on chromosome 10 (PTEN) aberrations are common in breast cancer (BC). PIK3CA mutation is associated with lower pCR rates especially in patients treated with double anti-HER2 therapy (Loibl et al. JCO accepted). Another mechanism of resistance for trastuzumab-based treatment could be loss of PTEN, resulting also in downstream activation of the pathway. We investigated the correlation between PIK3CA, PTEN, p4EBP1 (phosphorylated E4 binding protein 1) and pCR in pts receiving neoadjuvant therapy.

Methods: In addition to PIK3CA we retrospectively evaluated PTEN and p4EBP1 by immunohistochemistry in HER2+ patients who received EC followed by docetaxel within the G4 study (Untch et al. 2011). The G4 study demonstrated a higher pCR rate by adding trastuzumab to chemotherapy. HER2 and hormone receptors (HR) were centrally assessed. PTEN was assessed using the automated quantitative immunofluorescence analysis (Aqua) using an antibody (Cell Signalling Technology). p4EBP1 assessed by immunohistochemistry with an immunoreactive score ranging from 0-12. PTEN was categorized by an optimized cut-off determined by the cut-off finder software (http://molpath.charite.de/cutoff/) and p4EBP1 was measured as a continuous variable and correlated with PIK3CA genotype and pCR (ypT0, ypN0). Central HER2+ve cases with a tumor cell content of ≥20% were selected (n=181).

Results: Median age was 48 years (22-77); HR+ve 51%; Grade 3, 47.4%; pCR rate 32%. p4EBP1 analysis was available from 137 and PTEN from 108 patients. PIK3CA genotype was available in 83 of these patients. 58 pts had PIK3CA and PTEN assessable, 14/58 had a PIK3CA mutation (mut) (25%). Overall, pCR rate in PTEN low tumors was 27.6% vs 57.1% in PTEN high (p=0.010). Within the PIK3CA mut cohort 13/14 (92.9%) tumors were PTEN low. Within the PIK3CA wild-type (wt) cohort 30/44 (68.2%) were PTEN low (p=0.066). The tumours were grouped into 4 subsets using PIK3CA (mut vs wt) and PTEN (low vs. high). pCR rate was 57.1% (8/14) in PTEN high/PIK3CA wt cohort and decreased to 15.4% in the PTEN low/PIK3CA mut cohort. The group with either PTEN low and PIK3CA wt or PTEN high and PIK3CA mut had a pCR rate of 32.2% (p=0.015). In multivariable analysis after adjustment for baseline parameters PTEN was an independent predictor for pCR in the complete cohort (OR 12.3 [95% CI 1.82-82.9] p=0.010) and in PIK3CA wt cohort (OR 10.3 [95% CI 1.31-81.62] p=0.027). Within the HR+ve group PTEN low tumors had a pCR rate of 22.2% vs 61.5% in the PTEN low/PIK3CA mut cohort (p=0.007). In multivariable analysis PTEN was independently predictive for pCR in the HR+ve group (OR 49.5 [95% CI 3.4-707] p=0.004). p4EBP1 correlated weakly with PIK3CA (p=0.049) but not with PTEN. There was no association of p4EBP1 with pCR.

Conclusion: Low PTEN was significantly associated with lower pCR and added independent predictive information not only in the overall HER2+ve cohort but also in the PIK3CA wt and HR+ve cohort. It will be confirmed in a larger sample size if PTEN assessment adds information to PIK3CA genotype to select patients with low pCR rates after trastuzumab therapy.
Title: HER2/PIK3CA\textsuperscript{H1047R} transgenic mammary tumors develop acquired resistance to triple therapy with trastuzumab, pertuzumab and PI3K inhibitors via multiple mechanisms

Ariella B Hanker\textsuperscript{1}, Benjamin Bulen\textsuperscript{1}, Monica Red Brewer\textsuperscript{1}, Christian D Young\textsuperscript{1}, Kirsten M Farrar\textsuperscript{1}, Rebecca S Cook\textsuperscript{1}, Thomas P Stricker\textsuperscript{1} and Carlos L Arteaga\textsuperscript{1}. \textsuperscript{1}Vanderbilt University, Nashville, TN.

Body: HER2 amplification and activating mutations in PIK3CA, the gene encoding the p110\textalpha subunit of PI3K, often co-occur in breast cancer. We generated a transgenic mouse model of HER2-overexpressing (HER2+), PIK3CA\textsuperscript{H1047R}-mutant breast cancer. In these mice, PIK3CA\textsuperscript{H1047R} accelerates HER2-mediated mammary epithelial transformation and metastatic progression, confers stem cell-like properties to HER2-overexpressing cancers and generates resistance to the combination of trastuzumab and pertuzumab (Hanker et al. PNAS 2013). HER2+/PIK3CA tumor growth was inhibited by treatment with the HER2 antibodies trastuzumab and pertuzumab in combination with the pan-PI3K inhibitor BKM120 (TPB). We sought to discover mechanisms of acquired resistance to the triple therapy by long-term treatment of established HER2+/PIK3CA tumors. We used tumor transplants derived from two HER2+/PIK3CA transgenic mice, #564 and #635. Tumor transplants from model 564 were initially growth inhibited by TPB, but did not regress. A subset of 564 transplants (3/11) resumed growth in the presence of continuous TPB therapy. All transplants (n=9) from model 635 regressed to a volume of <100 mm\textsuperscript{3} within 6 weeks of treatment. All tumors recurred and 2 tumors continued growth when re-treated with TPB. Resistance was maintained following passaging in mice and tumors were cross-resistant to trastuzumab/pertuzumab/BYL719, a p110\textalpha-specific inhibitor. TPB-resistant tumor 635-2 expressed p95 HER2, which was not detected in untreated tumors. In contrast, HER2 expression was significantly reduced in TPB-resistant tumor 635-3. P-AKT remained suppressed in some resistant tumors, but was restored in others. Short-term TPB treatment strongly suppressed P-S6 in sensitive tumors, whereas P-S6 was no longer inhibited in all TPB-resistant tumors from both models. We are currently performing whole-exome sequencing and RNA-sequencing on TPB-resistant vs. untreated tumors in order to identify additional mechanisms of resistance. In parallel, we established human HER2+, PIK3CA-mutant cell lines (MDA-MB 453, UACC893, and HCC1954) resistant to TPB by long-term treatment (>5 months) in the presence of the three drugs. Similar to the TPB-resistant tumors, P-S6 was no longer inhibited following TPB treatment in the resistant cell lines. Treatment with the TORC1/2 inhibitor MLN0128 abolished levels of P-S6 in HER2+/PIK3CA\textsuperscript{H1047R} tumors. Combined treatment with MLN0128 and TPB inhibited growth of the drug-resistant tumors. Interestingly, Both TPB-resistant HER2+/PIK3CA\textsuperscript{H1047R} tumor lines displayed resistance to the antibody-drug conjugate trastuzumab-DM1 (T-DM1) \textit{in vitro} and \textit{in vivo}, despite maintenance of HER2 overexpression. In addition, HCC1954 cells selected for resistance to TPB in culture were 66-fold less sensitive to T-DM1 than parental cells, despite maintaining equal levels of HER2 by western blot. These data suggest that multiple mechanisms may contribute to resistance to dual HER2 and PI3K blockade, including re-activation of mTOR signaling. We speculate that a similar heterogeneity of resistance mechanisms may occur in HER2+/PIK3CA-mutant metastases in patients.
Title: The long noncoding RNA M41 promotes aggressiveness and tamoxifen resistance in ER-positive breast cancers

Felix Y Feng¹, Teng Ma¹, Corey Speers¹, Matthew K Iyer¹, Shuang Zhao¹, John R Prensner¹, James M Rae¹, Lori J Pierce¹ and Arul M Chinnaiyan¹. ¹University of Michigan, Ann Arbor, MI.

Background: Long noncoding RNAs (lncRNAs) have recently been associated with the development and progression of a variety of human cancers. To date, the interplay between known oncogenic drivers, such as estrogen receptor (ER), and lncRNAs has not been well described. In this study, we identify M41 as the top outlier lncRNA in ER-positive vs ER-negative breast cancer and investigate its role in preclinical cancer phenotypes and clinical outcomes.

Methods and Materials: RNA sequencing was performed on 89 breast cancer samples and cell lines, including 42 ER+ cases, and a modified cancer outlier analysis was used to identify lncRNAs enriched in ER-positive disease. To assess ER regulation of the top enriched lncRNA (M41), ChIP-Seq and ChIP-PCR was used to detect binding of ER to M41 promoter and qPCR was used to determine changes in M41 expression following 10 nM estradiol treatment in MCF7 and T47D cells. Following knockdown via siRNA, the impact of M41 expression was assessed on cell invasion, migration, proliferation, and anchorage-independent growth. The impact of M41 knockdown on tamoxifen sensitivity was assessed by cell proliferation studies in MCF7 cells with acquired tamoxifen resistance. Lastly, clinical associations between M41 expression and grade/node status, as well as event-free survival (EFS), was determined using ANOVA and Kaplan-Meier analyses of TCGA samples.

Results: M41, an uncharacterized lncRNA located on chr21q22.2, was identified as the top outlier lncRNA in ER-positive vs ER-negative breast cancer. M41 demonstrated outlier expression (RPKM values>50) in 15% of ER-positive cancers, and was not significantly expressed in normal breast tissue. ChIP studies show that ER robustly binds to the M41 promoter. Estradiol stimulation significantly increased M41 expression in a time-dependent manner. Knockdown of M41 significantly inhibited all assessed oncogenic phenotypes in the ER-positive MCF7 and T47D cells, with a 60-80% decrease in both invasion and anchorage-independent growth, but had no effect in the ER-negative MDA-MB-231 cell line (which has minimal M41 expression). M41 expression was greater than 10-fold higher in tamoxifen-resistant MCF7 cells compared to parental controls (p<0.001), and knockdown of M41 restored tamoxifen sensitivity on cell proliferation studies; studies on the mechanism of M41-mediated tamoxifen resistance are ongoing. M41 overexpression was significantly correlated with node positivity, increasing grade, and luminal B subtype in ER-positive breast cancer samples (p<0.001). In TCGA samples, M41 overexpression was significantly associated with decreased EFS (p=0.003).

Conclusion: We have identified M41 as an ER-associated oncogenic lncRNA that contributes to preclinical cancer phenotype, promotes tamoxifen resistance in cell line models, and associates with poor outcomes in clinical samples. We suggest that M41 represents a novel biomarker candidate for the prognosis of ER-positive breast cancers and provides new insight into the biological complexity of breast tumor biology.
**Title:** FoxA1 gene amplification in ER+ breast cancer mediates endocrine resistance by increasing IL-8

Duncan Cancer Center, Baylor College of Medicine, Houston, TX; \(^3\)Baylor College of Medicine, Houston, TX; \(^4\)Baylor College of Medicine, Houston, TX; \(^5\)Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA; \(^6\)Oregon Health & Science University, Portland, OR and \(^8\)Oregon Health and Science University, Portland, OR.

**Body:** Background: ER transcriptional programming is associated with fundamental changes when endocrine resistance develops. The Forkhead transcription factor, FoxA1, is a pioneer factor for ER-DNA binding. We hypothesize that FoxA1 plays a critical role in ER transcriptional reprogramming in endocrine resistance by augmenting itself and the specific downstream effectors. Methods: Next generation sequencing was applied to characterize a panel of endocrine-resistant (Endo-R) cell models. Genomic PCR amplification and FISH assays were developed to measure FoxA1 copy number gain (CNG). Q-RT-PCR, Western blots, IHC, ELISA, and cytokine arrays were used to determine the levels of FoxA1 and IL-8 in cell culture and in vivo xenograft tumors. Effects of gene knockdown (ER, FoxA1, or IL-8) or inducible FoxA1 overexpression on ER and growth factor receptor (GFR) downstream signaling were determined by cell growth and Western blots. ER and FoxA1 binding at the IL-8 gene locus was measured by ChIP-qPCR. ChIP-seq analysis was integrated with RNA-seq data. Kaplan-Meier analysis evaluated the predictive role of FoxA1 in ER+ breast tumors. Results: Exome-seq revealed that FoxA1 is the most highly amplified gene in TamR vs. P cells from two independent MCF7 models. Genomic PCR and FISH also indicate FoxA1 CNG in Endo-R models of ZR75-1 and BT474. Increased FoxA1 expression was found in multiple Endo-R cells and in MCF7L Endo-R xenograft tumors. Cytokines, especially IL-8, are more highly expressed in multiple Endo-R cell models, similar to our previous microarray data from MCF7 Endo-R xenograft tumors. FoxA1 forced overexpression significantly induced IL-8 expression in MCF7L-P cells. It also activated multiple GFR downstream signaling pathways, and conferred endocrine resistance. Conversely, knockdown of either FoxA1 or ER significantly decreased IL-8 levels in TamR cells, and inhibited cell growth in both P and TamR cells. Knockdown of IL-8 in TamR cells substantially inhibited GFR downstream signaling, and was more cytotoxic than in P cells. A novel FoxA1-binding site (10 kb at 5'UTR of IL-8) recruited more FoxA1 and p300 in MCF7L-TamR than -P cells. ChIP-seq shows a general enhancement of FoxA1 binding around the genes (within 20 kb) that are differentially expressed in TamR vs. P cells. We identified a FoxA1 CNG-associated gene signature from TCGA breast tumors that predicts worse relapse-free survival (RFS) in Tam-treated ER+ tumors (from Loi et al). Meta-analysis showed that FoxA1 mRNA levels in the top 25th percentile predict worse RFS in ER+ patients treated with Tam (N=615), but not in systemically untreated patients (N=500). FoxA1 CNG and overexpression in clinical specimens by using our newly developed FISH and IHC assays are currently being investigated. Conclusions: FoxA1 gene amplification was enriched in two independent MCF7 Tam-R cell models. Clonal selection of FoxA1 gene amplification may occur and lead to endocrine resistance. High levels of FoxA1 may mediate endocrine resistance by directly inducing IL-8. The data suggest that IL-8 signaling is a component of a cytokine loop controlled by the FoxA1/ER transcriptional reprogramming, which might be exploited in therapeutics to overcome endocrine resistance.

Title: Recurrent ESR1 fusion transcripts are associated with endocrine resistance in estrogen receptor positive, HER2 negative breast cancer

Jennifer M Giltnane¹, Justin M Balko¹, Thomas L Stricker¹, Christian Young¹, M Valeria Estrada¹, Nikhil Wagle², Eliezer van Allen², X Jasmine Mu², Violeta Sanchez¹, Jaime Farley¹, Kerry Fitzgerald³, Armin Graber³, Joseph A Pinto⁴, Franco Doimi⁴, Henry Gómez⁵, Monica Rizzo⁵, Thomas B Julian², Vandana Abramson¹, Ingrid Mayer¹, Mark Kelley¹, Ashwini Yenamandra¹, Ferrin C Wheeler¹, Melinda Sanders¹, Levi Garraway⁵, Ingrid Meszoely¹ and Carlos L Arteaga¹. ¹Vanderbilt-Ingram Cancer Center, Vanderbilt University, Nashville, TN; ²Broad Institute of Harvard & MIT, Cambridge, MA; ³Genoptix, Carlsbad, CA; ⁴Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru; ⁵Emory University, Atlanta, GA; ⁶Allegheny General Hospital and NSABP, Pittsburgh, PA and ⁷Oncosalud-AUNA, Lima, Peru.

Body: Breast cancer proliferation measured by Ki67 immunohistochemistry after short-term antiestrogen therapy has been shown to correlate with disease-free survival. This suggests the use of biomarkers of the early effects of endocrine therapy on ER+ tumors will identify resistant cancers. Thus, we hypothesized that profiling operable ER+ tumors after short term treatment with an aromatase inhibitor would discover actionable molecular alterations causally associated with resistance to estrogen deprivation.

We performed whole exome sequencing, RNA-Seq and quantitative immunofluorescence (QIF) of ER, PR, HER2, and Ki67 in biopsies from 130 patients with an operable ER+/HER2– breast cancer that had received letrozole for 10-21 days prior to surgery. Tumors were categorized by the natural log of 2-week post-letrozole Ki67 as sensitive, intermediate, or resistant.

We sequenced RNA from 50 frozen tumors and performed fusion transcript analysis using 4 programmatic algorithms (dRanger, TopHat, DeFuse, Chimera Scan), resulting in 304 candidate gene fusions in 44 tumors. Primers with universal sequencing tags were designed against 3' and 5' sites of breakpoints mapping to RefSeq exon coding regions (n=187); fusion sequences were amplified by qRT-PCR from tumor and breast cancer cell line RNA. Single or multiple distinct product bands were visualized by gel electrophoresis in 96 tumor samples and Sanger-sequenced. Results were mapped to the human RNA reference transcriptome using BLAST.

Overall, 9% of putative fusion transcripts (n=27 from 16 unique tumors) were validated by mapping to the open reading frames of predicted 3’ and 5’ genes. Fusion transcripts called by more than one program were more likely to validate (13 of 24 redundant versus 14 of 269 unique; p<0.001). ESR1 fusions in 4 tumors mapped to chromosome 6q25.1, involving the 5’ UTR of ESR1 and 3’ exons of AKAP12, c6orf211, and CCDC170 (c6orf97). The ESR1:CCDC170 fusion was also detected in MDA361 and MCF7 cells as previously published, as well as in BT474 cells. FISH for multiple probes at 6q25.1 demonstrated structural rearrangements but not amplification in primary tumors and breast cancer cell lines.

Using the 2-week Ki67 to stratify for response to treatment, the validated ESR1 fusions were present only in tumors that maintained high (≥7.4%) to intermediate (>2.7%) Ki67 labeling indices upon estrogen deprivation with letrozole (p=0.01). PR expression was lower (p=0.003) and ER expression higher (p=0.05) in ESR1 fusion+ tumors compared to fusion negative tumors. RNA extracted from 14 additional tumors were screened for ESR1 fusions by qRT-PCR and the ESR1:CCDC170 fusion was validated in 1 of 8 resistant/intermediate and 0 of 6 sensitive tumors.

In summary, biomarkers of early response to antiestrogens are needed in order to identify ER+ cancers that are treatment resistant. In a prospective trial of operable ER+/HER2– breast tumors, we discovered recurrent intrachromosomal ESR1 fusion transcripts associated with intrinsic resistance to estrogen deprivation with letrozole. Additional work investigating the genomic basis and function of the fusion transcripts is underway.
Title: ESR1 gene fusions implicated in endocrine therapy resistance of ER+ breast cancer

Jieya Shao¹, Jin Zhang¹, Robert J Crowder¹, Rodrigo Goncalves¹, Chanpheng Phommaly¹, Breast AWG and Network⁴, Charles M Perou², Christopher A Maher³, E Aubrey Thompson³ and Matthew J Ellis¹. ¹Washington University School of Medicine, St Louis, MO; ²University of North Carolina, Chapel Hill, NC; ³Mayo Clinic, Jacksonville, FL and ⁴Cancer Genome Atlas.

Body: Background. We recently identified an in-frame ESR1 translocation in a tumor and PDX pair from a patient with endocrine therapy resistant advanced disease. The fusion gene preserved the N-terminal 365aa of ESR1 containing the intact activation function 1 (AF1), DNA-binding domain (DBD) and hinge, followed by the C-terminal transactivation domain of YAP1. The ESR1-365>YAP1 fusion drove estrogen-independent and anti-estrogen-resistant tumor cell growth (Cell Reports 4:1116, 2013). We therefore sought to further investigate the role of ESR1 fusion genes in breast cancer.

Methods. 711 cases from TCGA, 82 ER+ cases from neoadjuvant endocrine therapy trials and 25 ER+ systemic relapse samples were screened for fusion genes using RNAseq. Fusion genes involving ESR1 were subsequently assayed for estrogen response element (ERE)-mediated transcriptional activity and ability to drive estradiol independent breast cancer cell growth.

Results. Multiple ESR1 fusions were identified in mostly luminal B cancers. ESR1 fusions resulted most frequently from rearrangements involving another gene on Chromosome (Chr) 6 but also fusions with genes on other chromosomes. The fusions involving partners on Chr6 that retained an intact N terminal AF1 and DNA binding domain (DBD) of ESR1 (≥1-253aa) included an Out-of-Frame (OF) fusion event with CCDC170 (a gene immediately centromeric to ESR1), POLH (in-frame or IF), AKAP12 (IF), PCMT1 (OF), SYNE1 (OF) and GPR126 (OF). Also identified were inter-chromosomal translocations involving Chr12p-NOP2 (IF) and ChrX-PCDH11X (IF) and Chr7q-AKR1D1 (OF). The ESR1 fusions with transcriptional potential (because of a retained DNA binding domain) included variable 5’ ESR1 exons that preserved 253aa, 365aa, 412aa or 458aa of ESR1 sequence: in all cases disrupting ligand binding though loss of C terminal sequence. The effect of the IF and OF 3’ sequences on the transcriptional activity of the relevant ESR1 fragment was highly variable. The most transcriptionally active fusion (more active than the relevant ESR1 fragment alone) was the ESR1-365>YAP1 as well as ESR1-365>PCDH11X and ESR1-253>CCDC170. This is remarkable since PCDH11X is not considered a transcription factor and the CCDC170 sequence was OF – in both cases suggesting the activity of the fusion was due to "neomorphic" properties. Two fusions, NOP2 and POLH were inactive in the ERE reporter assay, yet both stimulated estradiol independent growth. In these cases we suggest that the ESR1 locus can function as a "promoter trap" which allows the identification of genes with previously unknown functions in endocrine therapy resistance.

Conclusions: In luminal-type breast cancer the ESR1 gene was fused to multiple 3’ partners with remarkably heterogeneous functions. The two most transcriptionally active, ESR1-365>YAP1 and ESR1-365>PCDH11X, were both identified in endocrine therapy refractory advanced disease – suggesting a role in fatal disease progression.
Title: Profiling of ESR1-mutated metastatic breast cancers by FoundationOne® allows a broad genomic understanding for potential clinical implications

Norma A Palma1, Siraj Ali1, Garrett Frampton1, Kai Wang1, Hannah Gilmore2, Julio Peguero6, Lyndsay N Harris2, Massimo Cristofanilli5, Juliann Chmielecki1, Jeffrey S Ross1,4, Deborah Morosini1, Vincent A Miller1, Phil J Stephens1, Gary Palmer1 and Joyce O'Shaughnessy2. 1Foundation Medicine, Cambridge, MA; 2Case Western Reserve University, Cleveland, OH; 3Baylor Charles A. Sammons Cancer Center, Texas Oncology, US Oncology, Dallas, TX; 4Albany Medical College, Albany, NY; 5Thomas Jefferson University, Kimmel Cancer Center, Philadelphia, PA and 6Oncology Consultants Research, Houston, TX.

Body: Background: Estrogen receptor (ER) inhibition is an important treatment option for advanced breast cancer (BC) pts. Recent studies describe recurring somatic mutations in codons 537 and 538 within the ligand-binding domain (LBD) of ~20% of ER+ metastatic disease, but not treatment-naïve ER+ cancer or ER-negative disease, that render the ER constitutively active and confer partial resistance to endocrine agents. Few studies have described the clinicopathologic and genomic covariates that accompany the ESR1 genomic alterations (GAs). Correlating genomic events as captured by FoundationOne in pts with ESR1-mutated BCs with clinical history may provide clinical insight into these alterations.

Methods: Hybridization capture of 3769 exons of 236 cancer-related genes and 47 introns from 19 genes that are frequently rearranged in cancer were fully sequenced to high, uniform coverage using FoundationOne (Foundation Medicine, Cambridge, MA).

Results: 176 of the 2,208 (7.9%) BC pt cases harbored ESR1 alterations. 1127 short variants (SV) were detected in 176 patient samples for an average of 6.4 GA/sample. 16.5% SV (186/1127) were ESR1 GAs with an average of 1.0 ESR1 GAs/sample. ESR1 GAs consisted of base substitutions (77%) and amplifications (20%, median copy number 9X, range 6-28). Base substitutions occurred at codons 538 (71/145) and 537 (70/145) and at two other novel sites, 341 (2/145) and 563 (1/145). A patient-derived xenograft study suggested that tumors refractory to ER inhibitors and harboring ESR1 amplification could be responsive to higher doses of estradiol. (Li et al, Cell Reports, 2013). The most frequently co-occurring GAs were PIK3CA (37.5%), GATA3 (22.7%), TP53 (24.4%), MAP3K1 (10.2%) and CDH1 (7.9). Collection of data on tissue sites sequenced, treatments and outcomes on these pts with ESR1 GAs are ongoing. Of note, one pt had recurrent disease following adjuvant tamoxifen and letrozole. FoundationOne testing of her recurrent bony disease revealed an ESR1 Y537 alteration along with mutations in PIK3CA, APC, and RAD51. She has been on fulvestrant monotherapy with stable metastatic disease 13 + months.

Conclusions: We found through FoundationOne testing that ESR1 GAs are reasonably common in advanced BCs, with base substitutions accounting for 77% of ESR1 GAs and amplifications for 20%. Identification and characterization of ESR1-mutated advanced BC pts by comprehensive genomic profiling capable of detecting both base substitutions and copy number changes may identify clinically relevant GAs. Clinical correlation is pending.
Title: Estrogen receptor (ESR1) mutations confer resistance to hormone therapy using a common mechanism

Luca Gelsomino\textsuperscript{1}, Guowei Gu\textsuperscript{1}, Yassine Rechoum\textsuperscript{1}, Sebastiano Ando\textsuperscript{2} and Suzanne AW Fuqua\textsuperscript{1}. \textsuperscript{1}Baylor College of Medicine, Houston, TX and \textsuperscript{2}Universita' della Calabria, Arcavacata di Rende, Cosenza, Italy.

Body: Background: The idea that somatic estrogen receptor gene (ESR1) mutations could play an important role in the evolution of hormone-responsive breast cancers was proposed by us with our original identification of two ESR1 mutations at residues K303 and Y537. Technical issues with ESR1 mutation detection and the resulting paucity of reports in tumors led many to assume that ESR1 mutations were not there. However, with recent Next Generation Sequencing of metastatic tumors, mutation of ESR1 is now an accepted certainty. ESR1 mutant allele frequencies vary over a wide dynamic range, and are usually a minority population within tumors. Therefore how does a minor subclonal tumor population drive resistance in metastatic tumors?

Methods: MCF-7 cells expressing endogenous wild-type ER was transduced with ESR1 mutants K303R, Y537N, Y537S, and D538G lentivirus and stable clones selected. ER transcriptional assays and growth in soft agar were performed. Digital drop (dd) PCR and primer extension snp detection were used to ascertain mutant:WT ESR1 allele frequency in cell lines, 200 primary tumors from patients treated with tamoxifen monotherapy, and 20 metastatic breast tumors.

Results: Mutant ER constitutive transcriptional activity was fully antagonized by the antiestrogens tamoxifen or fulvestrant in MCF-7 stable transfectants. In contrast, soft agar growth of all ESR1 mutant-expressing cells was unexpectedly and completely resistant to the growth inhibitory effects of tamoxifen, although mutant-expressing cells were a minority subpopulation in the stable clones. Therefore, in cells with WT ER co-expression, the mutant resistant phenotype dominates. We found that phosphorylation of IGF1R\texttextsuperscript{β}; was constitutively increased in all ESR1-mutant expressing cells. Treatment with a specific IGF1R\texttextsuperscript{β} inhibitor in combination with tamoxifen drastically restored hormone sensitivity in cells expressing the ESR1 mutations. These results suggest a convergence in resistance mechanisms between the K303R and Y537 ESR1 mutation hot spots. We are exploring whether the dominant mutant ESR1 resistant phenotype occurs via activation of paracrine mediators, and have identified altered IGF-1 and interleukin 6 signaling in mutant-expressing cells. Mutation detection in a retrospective cohort of primary and metastatic breast tumors is ongoing and will be presented.

Conclusions: We hypothesize that the selection of dominant-acting ESR1 mutations in tumors is a key event in breast cancer progression, potentially due to the selective pressure of antiestrogens. The dominant-resistant phenotype of ESR1 mutants in a majority WT background supports the subclonal evolution of ESR1 mutations in breast cancer recurrence. A common resistance mechanism (like constitutive IGF1R\texttextsuperscript{β} activation) should enable biologic targeting of ESR1 mutation-positive metastatic patients a feasible clinical goal.

Title: In-silico discovery of novel estrogen receptor-α inhibitors as potential therapeutics for tamoxifen resistant breast cancer

Kriti Singh¹, Ravi SN Munuganti¹, Miriam Butler¹, Artem Cherkasov¹ and Paul S Rennie¹. ¹Vancouver Prostate Centre, University of British Columbia, Vancouver, BC, Canada.

Body: Estrogen receptor-α (ER) positive breast cancer (BCa) represents 75% of all invasive BCAs. Conventional ER-directed drug Tamoxifen targets the estrogen binding pocket (EBP) of the receptor. However, over prolonged periods of treatment, the therapeutic efficacy of Tamoxifen declines due to development of resistance. Numerous factors are causative for this phenomenon, including recently reported mutations in the receptor (T537S). Therefore, there is an urgency to develop novel anti-ER therapeutics that exhibit entirely different mode of ER inhibition. A promising alternative strategy is to prevent receptor-coactivator interaction and block further crucial steps in ER activity. ER-coactivator interface should be less prone to adaptive mutations as any mutations at this site would also likely block the coactivator recruitment, we therefore targeted the Activation Function-2 (AF2) site, a coactivator binding pocket on ER, called to overcome the limitations of Tamoxifen. Although AF2 is a shallow surface pocket, the pharmacophore-rich features of this site make it a druggable target. To identify potential ER AF2 inhibitors, virtual screening was performed. Initial hits were subjected to lead optimization and more potent analogues were rationally designed by exploiting critical features of this site. Potential compounds were tested for their ability to inhibit ER transcriptional activity using the T47D-KBluc cell line stably transfected with an ER-specific luciferase reporter. Consequently, the lead compound VPC-16339 (IC50=8.24µM) was identified. The direct binding between VPC-16339 and the receptor was confirmed by Biolayer Interferometry assay. More importantly, VPC-16339 prevents coactivator recruitment at the AF2 pocket in a dose dependent manner as measured by TR-FRET coactivator recruitment assay. Increasing concentrations of estradiol did not affect the IC50 of the lead compound, thereby ruling out the possibility of VPC-16339 binding to EBP. VPC-16339 demonstrated a strong anti-proliferative effect on MCF7 and Tamoxifen resistant cells, with no effect on ER-HeLa cells, suggesting its selective ER-mediated action, as further validated by ER luciferase assay in Tamoxifen resistant cells. VPC-16339 effectively inhibits mRNA and protein expression levels of the estrogen dependent genes such as pS2, CathD and CDC2. Due to AF2-guided mechanism, VPC-16339 successfully overcomes Tamoxifen resistance and inhibits the constitutively active Tamoxifen resistant form of ER (T537S).

In summary, we report VPC-16339 as an ER AF2 specific inhibitor with promising anti-proliferative effect in BCa cell lines including Tamoxifen resistant cell lines. VPC-16339 effectively inhibits the mutant form of the receptor (T537S) which is responsible for acquired endocrine resistance. It can be anticipated that ER AF2 inhibitors will provide an alternative therapeutic strategy that can be applied concurrently or simultaneously with current anti-ER treatments for BCa patients with advanced disease.
Title: TransCONFIRM: The correlative analysis of breast tumors from patients with advanced hormone receptor positive disease identifies a genetic signature associated with decreased benefit from single agent fulvestrant

Body: Introduction: Several multi-gene expression based assays have been developed to assess the prognosis and predict response to endocrine treatments in early stage hormone receptor positive (HR+) breast cancer. Although a significant number of patients with metastatic ER+ disease will not respond to endocrine treatments, molecular assays to predict response in this setting are limited. In addition, tissue specimens of metastatic lesions for molecular studies are not always available. In this study we sought to identify a molecular profile in the primary tumors of patients who developed disease recurrence that could predict response to endocrine treatment in metastatic disease.

Methods: We used the primary breast tumor samples from a subgroup of patients participating in the randomized phase III CONFIRM trial, which compared 500mg versus 250mg of fulvestrant in post-menopausal women with HR+ advanced breast cancer. Formalin- fixed paraffin embedded tumors were collected from 130 of the participants and were centrally reviewed for ER, PR, HER2 and Ki67. RNA was sufficient for gene expression profiling in 112 of the cases using the NuGEN Ovation FFPE WTA System and Affymetrix HTA 2.0 GeneChip. The majority of the patients in this analysis developed metastatic disease during adjuvant endocrine treatment (N=55) or had de-novo metastatic disease (N=39) versus relapse after adjuvant treatment (N=18). The association between gene expression and progression free survival (PFS) was investigated using a multivariate Cox proportional hazard model adjusting for statistically significant clinicopatholgical factors. In addition we performed pathway-level analysis and evaluated the PAM50 subtype predictor and Risk of Relapse (ROR) score.

Results: The median PFS was 8 months in our cohort. HER2 level by immunohistochemistry above 1+, high PR level, defined as Allred score of above 6, and Ki67 of above 50% were significantly associated with PFS and were included in the multivariate model. Dose of fulvestrant was not associated with PFS in this cohort. We identified a signature of 25 genes that is inversely associated with PFS on fulvestrant treatment (FDR 20%). When compared to other published datasets of breast cancer tumors, these genes are enriched in tumors with poor outcome and triple negative cancers. Pathway analysis revealed an association between activation of the EGFR pathway and decreased PFS (P=0.01). PAM50 subtypes varied with the luminal subtype being the most common (65%) and were generally concordant with the clinical subtype. However, we did not detect a significant trend between PAM50 subtype or ROR score and PFS or overall survival.

Conclusions: In this cohort of patients with early and de-novo metastatic disease we identified a gene signature in the primary tumors that is associated with decreased response to fulvestrant treatment in metastatic disease. This signature warrants further validation to determine it’s predictive value and potential to assist in treatment decision making for patients with HR+ metastatic disease.

Title: Prognostic effects of gene mutation in estrogen receptor positive breast cancer

Obi L Griffith¹, Malachi Griffith¹, Jingqin Luo¹, Jasreet Hundall¹, Christopher A Miller¹, David E Larson¹, Robert Fulton¹, Richard K Wilson¹, Shuzhen Liu², Samuel Leung², Torsten O Nielsen², Elaine R Mardis¹ and Matthew J Ellis¹. ¹Washington University School of Medicine, St Louis, MO and ²University of British Columbia, Vancouver, BC, Canada.

Body: Background: Relationships between recurrent somatic mutations and outcome in estrogen receptor positive (ER+) breast cancer has not been extensively studied as the original discovery efforts were from either heterogeneously treated patients or follow up was too brief. Targeted massively parallel sequencing (MPS) analysis was therefore conducted on DNA extracted from archived formalin-fixed breast primaries from a cohort of over 600 patients from British Columbia treated with five years of adjuvant tamoxifen monotherapy and followed for over 10 years (Nielsen et al CCR 16:5222, 2010).

Methods: Genes were selected for targeted sequencing by meta-analysis of five large-scale breast cancer sequencing studies and manual review of breast cancer literature. In total 83 genes were identified and 3286 probes were designed to tile across all known exons. Minimum starting input DNA was 50ng (mean=189.1ng). Illumina sequencing libraries were constructed, indexed, pooled, and enriched for target sequences by hybrid-capture followed by paired-end 100bp reads. The Genome Modeling System was used to perform single-tumor somatic variant prediction. Variant calls were filtered to include only targeted regions and exclude variants with global mutant allele frequencies greater than 0.1% in 1000 genomes or NHLBI exome datasets. Kaplan-Meier analysis and multivariable analysis (clinical features and intrinsic subtype by qPCR) was performed for breast-cancer-specific and relapse free survival.

Results: A total of 638 samples met minimum quality controls of 80% targeted space covered at 20X or greater. On average each sample had 332M of aligned bases and a mean coverage of 134.3X. In total 7,159 variants were identified including 3,696 missense, 494 nonsense, and 1,047 frameshift insertions or deletions. Preliminary results indicate significant associations between mutation status and improved survival for PIK3CA, ARID1B, ERBB3, MAP3K1 and GATA3 or worse survival for PTEN, DDR1, TP53 and JAK2. Five Y537N/C, two E380Q and 5 potentially novel ligand-binding-domain mutations were identified in ESR1. Such mutations were recently reported to be associated with resistance to hormone therapy but were discovered here in as much as 1.9% of pre-treatment samples. Analysis will be presented regarding the use of relapse events to differentiate passenger from driver mutations.

Conclusion. Multiple recurrently mutated genes have both positive and negative associations with prognosis in tamoxifen monotherapy treated breast cancer populations. Associations with poor outcome suggest that PTEN, DDR1, and JAK2 are high priorities for pharmacological interventions.

Title: Identification of base pair mutations and structural rearrangements acquired in breast cancer metastases including a novel hyperactive ESR1-DAB2 fusion gene specifically in hormone-resistant recurrence

Ryan J Hartmaier¹,², Shannon L Puhalla¹, Steffi Oesterreich¹,², Amir Bahreini¹,³, Nancy E Davidson¹,², Adam M Brufsky¹ and Adrian V Lee¹,²,³. ¹Women's Cancer Research Center, University of Pittsburgh Cancer Institute & Magee Women's Research Center, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA and ³University of Pittsburgh, Pittsburgh, PA.

Body: DNA structural variations (SVs) are a major source of genetic instability in cancer, but they remain understudied. Large-insert mate-pair sequencing (MPS) is a powerful method designed to detect SVs, even in highly repetitive regions. Using MPS and other methods, we performed a comprehensive analysis of genomic alterations in breast cancer progression. Matched primary/recurrent frozen tumor samples from 6 patients, including two patients from our rapid autopsy program with multiple metastatic tissues (20 total samples; average 5.5 years to recurrence) were examined by multiple large-insert library (3-5, 5-8, 8-12kb) MPS to identify metastatic acquired SVs. This was supplemented with RNAseq (n=15), whole exome sequencing (n=18; ~75x), whole genome sequencing (n=3; 40-65x), and SNP arrays.

A relatively small fraction (~10%) of somatic single nucleotide variants (SNVs) in the primary tumor were identified in matched metastatic samples, and the majority of metastatic SNVs were not found in the matched primary tumor. This indicates that a rare sub-clone colonizes the metastatic site and evolves extensively before becoming clinically evident. For example, in one patient with an ER+ tumor who initially declined anti-estrogen therapy, the recently described ESR1 Y537S mutation was not present in the primary tumor or in metastatic disease 5 years later. However, after extensive anti-estrogen treatment for metastatic disease, the mutation was identified at rapid autopsy, indicating that this mutation can be acquired even after initial metastatic spread. We observed extensive patient-to-patient variability in the number and types of SVs. In general, the overall pattern of SVs was remarkably similar between matched primary and metastatic samples, however, we identified a number of metastatic specific SVs that likely contribute to disease progression. Specifically, in one patient with an ER+ primary tumor treated with adjuvant Tamoxifen, we identified a novel fusion gene between ESR1 (estrogen receptor-α, ERα) and DAB2 (disabled-2) only in a lymph node recurrence. RT-PCR and western blot analysis confirmed that the fusion RNA/protein was expressed/translated only in the recurrent disease. The fusion retains the DNA-binding domain (DBD) and hinge region of ERα while the ligand-binding domain (LBD) is replaced with the majority of DAB2. We hypothesized that this is a functional genetic alteration conferring ligand-independent ERα-mediated signaling and growth. Confirming this, in vitro ERE-Tk-luc reporter assays showed that the ESR1-DAB2 fusion has ligand-independent activity that is 13-290x higher than wild-type ERα. Chromatin immunoprecipitation assays in metastatic tissue from tumors with mutant ERα show strong enrichment for ERα at classical ERα target genes. We are currently assessing the genome-wide binding of ESR1-DAB2 and the functional contribution of DAB2 to the fusion protein.

This study represents the most comprehensive analysis to date of genomic changes in breast cancer progression and indicates extensive changes occur during metastatic spread. A number of acquired changes likely represent therapeutically targetable metastatic dependencies.
Body: Aims
1. To determine the variability of mutational profiles and sub-clonality in core-cut biopsies from ER+ BC and the impact of 2-weeks’ AI therapy on these.
2. To identify mutations or patterns of mutations associated with poor anti-proliferative response to AI treatment.

Background
DNA alterations may lead to de novo and acquired resistance to medical therapies including AIs. Assessing this requires single time-point or sequential sampling usually with core-cuts but there is little information on their ability to represent mutational profiles or sub-clonal structure. We studied this in paired biopsies from ER+ BC primaries in 60 selected postmenopausal patients from the Peri-Operative Endocrine Therapy for Individualising Care (POETIC) trial (CRUK/07/015) before and after 2-weeks’ non-steroidal AI or no AI (randomised 2:1).

Methods
DNA was extracted from RNAlater-preserved diagnostic and surgical 14-gauge core-cut samples and peripheral blood from 20 no AI (Control) and 40 AI-treated patients (15 poor and 25 good Ki67-responders [PR and GR, respectively]). Patients with low ER+ BC or unsuppressed estradiol on treatment were not considered. Exome sequencing (Illumina HiSeq 2000) achieved >60% coverage across the exome at 15x depth. Variants were validated by re-sequencing (median >100x) together with 79 genes of interest curated from COSMIC and selected publications. Statistically significant genes (SMGs) were determined using MuSiC. Sub-clonality was analysed by SciClone.

Results
Good quality exomes were obtained on 102 samples including 44 pairs (control n=14; PR n=10; GR n=20). There were 5684 mutations (including 3616 missense and 1322 silent) affecting 3261 genes. SMGs in this series were PIK3CA (35.3%), TP53 (27.5%), CDH1 (13.8%), HEATR7B2 (8.8%), GATA3 (5.9%), CENPF (5.9%), MAP3K1 (5.9%), MAP2K4 (4.9%), HTR1A (2.9%) and C22orf23 (1%). PR had more mutations than GR (median 65 vs 36, p=0.04). More PR than GR were HER2+ (5/14 vs 1/24, p=0.019) and/or TP53-mutated (5/10 vs 3/20, p=0.08) but similar proportions were PIK3CA-mutated. The correlation of diagnostic vs surgical variant allele frequencies was strong for the control (r=0.75) and treated (r=0.89) groups (for treated GR r=0.83; for treated PR r=0.65). In the treated group there were fewer mutations at surgery vs diagnosis (p<0.026). PIK3CA and TP53 mutation status was identical between the paired samples in 41/44 and 40/44 cases; less frequently mutated genes showed lower concordance. SciClone plots to infer sub-clonality were possible in 37 pairs; for 8 pairs (22%) there was clear evidence of at least one sub-clone being present in only one core-cut sample.

Conclusion
This is the largest reported study of exome reproducibility in ER+ BC for mutation profiles based on core-cut biopsy. Multiple sub-clones are identifiable in ER+ primary BC. In c.20% tumours, a single core-cut does not allow inference of all sub-clonal populations, probably due to spatial heterogeneity. TP53 mutations but not PIK3CA mutations are associated with PR. Large numbers of BC will be needed to identify any associations of lower frequency mutations with resistance. A trend to fewer mutations after just 2 weeks AI needs confirmation.
Title: In-depth genomic analysis of ER+ breast cancers during development of endocrine resistance

J Michael Dixon¹, Arran K Turnbull¹, Chris Fan², Joel S Parker², Xiaping He², Laura Arthur¹, Carlos Martinez-Perez¹, Lorna Renshaw¹ and Charles Perou². ¹University of Edinburgh, Edinburgh, United Kingdom and ²Comprehensive Cancer Centre, Chapel Hill, NC.

Body: Background: Aromatase inhibitors (AIs) have an established role in the treatment of estrogen receptor alpha positive (ER+) post-menopausal breast cancer. Response rates are only 50-70% in the neoadjuvant setting and up to 40-50% of all adjuvantly treated patients will eventually relapse. Mutations in certain genes have been previously shown to confer resistance to therapy, and molecular subtype has associations with poor outcome (i.e. LumB and HER2E). In order to improve the outcomes of non-responders or patients who become resistant to endocrine treatment, the identification of key mutations, and their interaction with subtype, is crucial. Dynamic profiling of the same tumour demonstrating de novo or developing resistance after responding to one or more lines of endocrine treatment in the neoadjuvant setting provides a unique opportunity to identify such genomic changes.

Methods: This series is unique in that it includes 17 post-menopausal women with ER+ breast cancer treated with neoadjuvant letrozole. 13 of these patients progressed on treatment or initially responded to treatment and then developed acquired resistance and 4 responded well. Dynamic clinical response was assessed for each patient using periodic 3D ultrasound measurements performed during treatment. Fresh tissue was taken before treatment and when the tumor was resistant to treatment (4 patients had 2 biopsies, 9 patients had 3 and 4 patients had 4 available biopsies taken). RNA and DNA were extracted from tumour and normal DNA obtained from either matched blood or normal lymphatic tissue. In total, 51 tumour samples were available and have completed RNA-Seq, with exome sequencing shortly to be completed.

Results: From the RNA-seq data, the intrinsic subtype distribution was 9 LumA, 7 LumB, and 1 HER2-enriched; when stratified according to response, the "progressors" were 7 LumB, 5 LumA and 1 HER2-enriched, while "responders" were 3 LumA and 1 LumB. When examined in an unsupervised hierarchical clustering analysis along with >800 TCGA Breast tumor samples, 13/17 patients had all of their samples grouped immediately together, suggesting that the overall tumor phenotype was maintained. Interestingly, the most dominant change in gene expression was the observation that there were 5 "progressor" patients where the pre-treatment sample was LumB and all subsequent samples were LumA; we only observed one instance of a patient starting as LumA and changing to a LumB, who was also labelled as a "progressor". Full exome sequencing is underway and these results will be presented.

Conclusion: Genomic analysis of progression suggests that an apparent "subtype shift" appears in a number of patients where a shift to LumA is seen; this apparent change may be reflective of decreased proliferation rates caused by therapy, or the acquisition of a true LumA phenotype. We cannot differentiate between these two hypotheses at this time, but expect that the exome sequencing will help to differentiate between these two hypotheses given the large number of mutations and copy number alterations that can differentiate between LumA vs. LumB.
Title: Stromal tumor-infiltrating lymphocytes (S-TILs): In the alliance N9831 trial S-TILs are associated with chemotherapy benefit but not associated with trastuzumab benefit

Edith A Perez¹, Karla V Ballman², S Keith Anderson², E Aubrey Thompson¹, Sunil S Badve³, Helen Bailey⁴ and Frederick L Baehner⁴,⁵. ¹Mayo Clinic, Jacksonville, FL; ²Mayo Clinic, Rochester, MN; ³Indiana University, Indianapolis, IN; ⁴Genomic Health Inc, Redwood City, CA and ⁵University of California, San Francisco, CA.

Body: Background: Tumor-infiltrating lymphocytes (TILs) at diagnosis are reported to be prognostic in triple-negative breast cancer (BC). Analysis of a small subset of 209 HER2+ patients (pts) with 49 events concluded that higher levels of S-TILs are associated with increased trastuzumab benefit (Loi, 2014). Here we report the largest study to date evaluating S-TILs and their prognostic and predictive association with clinical outcome in N9831 pts treated with either chemotherapy or chemotherapy plus trastuzumab.

Methods: Samples assessed were from primary tumors of pts on N9831 arm A (standard AC→T chemotherapy) and arm C (concurrent chemotherapy with trastuzumab) (Perez, 2011). S-TILs were evaluated on H&E whole tumor slides by a single pathologist with ∼10% of cases read by two pathologists in tandem. The percent of stromal lymphocytic infiltrates (S-TILs) was quantitated in deciles; ≥60% S-TILs was used for the categorical cutoff (Denkert, 2010). The association between S-TILs, treatment (tx) and recurrence-free survival (RFS) was studied and the interaction between S-TILs, trastuzumab benefit and RFS was calculated.

Results: 489 pts from arm A (chemo) and 456 pts from arm C (chemo with trastuzumab) were assessed and were similar to pts in the overall trial; all had RFS information and a median follow-up of 4.4yr. Tumors from 54% of pts in arms A and C were HR+; 14% were node-negative. Tumors with high S-TILs were more likely to be hormone receptor-negative (p< 0.0001). In multivariable analyses including nodal status, hormone receptor status, tx arm, tumor size, tumor grade, and age, ≥60% S-TILs was significantly associated with RFS (HR 0.20; 95%CI 0.06–0.65, p=0.007) in arm A but not in arm C (HR 1.1; 95%CI 0.42–2.8, p=0.87); the interaction term of arm and ≥60% S-TILs was significant (p=0.042). Semi-continuous deciles were associated with RFS in arm A (p<0.0002) but not in C (p=0.37). Hormone receptor status was an independent prognostic factor in arm A (HR 0.61; 95%CI 0.41–0.93, p=0.02) but not in C (HR 0.79; 95%CI 0.44–1.41, p=0.42). In arm A the 10yr Kaplan-Meier estimates for RFS were 90.9% and 64.5% for high S-TILs and low S-TILs pts, respectively (HR 0.23; 95%CI 0.07–0.73, p=0.013). In arm C the 10yr Kaplan-Meier estimates for RFS were 80.0% and 80.1% for high S-TILs and low S-TILs pts, respectively (HR 1.26; 95%CI 0.5–3.2, p=0.63).

Conclusions: In exploratory analyses from this subset HER2+ population from N9831, S-TILs were associated with RFS in patients treated with chemotherapy alone, and were not shown to be associated with RFS in patients treated with chemotherapy plus trastuzumab.
Title: HER2 T cell dependent bispecific antibody (HER2-TDB) for treatment of HER2 positive breast cancer

Teemu T Junttila¹, Ji Li¹, Jennifer Johnston¹, Maria Hristopoulos¹, Robyn Clark¹, Diego Ellerman¹, Bu-Er Wang¹, Yijin Li¹, Mary Mathieu¹, Guangmin Li¹, Judy Young¹, Elizabeth Luis¹, Gail Lewis Phillips¹, Eric Stefanich¹, Cristoph Spiess¹, Andrew Polson¹, Bryan Irving¹, Justin M Scheer¹, Melissa R Junttila¹, Mark S Dennis¹, Robert Kelley¹, Klara Totpal¹ and Allen Ebens¹. ¹Genentech, San Francisco, CA.

Body: Based on recent clinical success of tumor immunotherapies that block immune suppressive mechanisms to restore T cell function, there is a profound interest in the clinical development of T cell targeted therapies. We have produced a trastuzumab-based HER2 T cell dependent bispecific antibody (HER2-TDB) that conditionally activates T cells resulting in lysis of HER2 expressing cancer cells at low picomolar concentrations. Due to its unique mechanism of action, which is unrelated to HER2 signaling or sensitivity to chemotherapeutic agents, HER2-TDB can eliminate cells refractory to currently approved HER2 therapies. The potent anti-tumor activity of HER2-TDB was demonstrated using four model systems including MMTV-huHER2 and huCD3 transgenic mice. We demonstrate inhibitory effect of PD-L1 expression on the activity of bispecific T cell recruiting antibodies. This resistance mechanism is reversed by anti-PD-L1 treatment and combination of HER2-TDB with anti-PD-L1 immune therapy resulted in enhanced inhibition of tumor growth, increased response rates and durable responses.

Significance:
This report presents a new immunotherapy for HER2+ breast cancer with an alternative, extremely potent mechanism of action that is effective in cells resistant to current HER2 targeted therapies. Several significant advances are provided to bispecific T cell recruiting antibodies: we characterize a critical resistance mechanism, a potential diagnostic marker, a novel transgenic efficacy model and significantly improve the drug-like properties by using technology based on full length antibodies with natural architecture. Finally we demonstrate the benefit of combining two immune therapies: direct polyclonal recruitment of T cell activity together with inhibiting the T cell suppressive PD-1/PD-L1 signaling results in enhanced and durable long term responses.
Reduced tumor lymphocytic infiltration in the residual disease (RD) of post-neoadjuvant chemotherapy (NAC) triple-negative breast cancers (TNBC) is associated with Ras/MAPK activation and poorer survival

Justin M Balko, Carsten Denkert, Roberto Salgado, Martin O'Hely, Peter Savas, Paul A Beavis, Phil K Darcy, Susan Combs, David L Rimm, Jennifer M Giltane, Monica V Estrada, Melinda E Sanders, Rebecca S Cook, Kai Wang, Vincent A Miller, Phillip J Stephens, Roman Yelensky, Joseph A Pinto, Frant J Stephens, Henry Gomez, Carlos L Arteaga and Sherene Loi. 1Peter MacCallum Cancer Center, Sydney, Australia; 2Charité University, Berlin, Germany; 3Institute Jules Bordet, Brussels, Belgium; 4WEHI University, Melbourne, Australia; 5Yale University, New Haven, CT; 6Vanderbilt University, Nashville, TN; 7Foundation Medicine, Cambridge, MA; 8Oncosalud, Lima, Peru and 9Instituto Nacional de Enfermedades Neoplásicas (INEN), Lima, Peru.

Body: Background: Tumor-infiltrating lymphocytes (TILs) are associated with improved prognosis in TNBCs, with several retrospective analyses demonstrating that TNBCs with high baseline TILs have higher rates of pathologic complete response (pCR) to NAC. Moreover, the TIL burden in the RD of patients who do not achieve pCR to NAC is also correlated with prognosis. However, insight into the molecular pathways in TNBC which modulate heterogeneity in host anti-tumor immune responses is lacking. To address this gap in knowledge, we analyzed TILs retrospectively in a cohort of clinically and molecularly characterized TNBCs with RD after NAC.

Methods: TILs were scored in H&E stained slides by expert pathologists in the post-treatment tumors of 92 NAC-treated TNBC patients with RD at the time of resection and in 44 matched baseline diagnostic biopsies. Genomic alterations in the RD were assayed using targeted next-generation sequencing (tNGS) while selected transcriptional signatures were evaluated by NanoString as previously published (Balko et al, Cancer Discovery 2014). Differences in pre- and post-NAC TILs were compared between tumors harboring alterations in cell cycle, PI3K/mTOR, growth factor receptors, Ras/MAPK and DNA repair pathways. Associations of TILs with transcriptional signatures were also tested.

Results: A strong positive association of TILs in NAC-treated specimens was observed with RFS (coxPH p=0.0001, relative risk reduction of 3.4% for each % of TILs) and OS (p=0.0016; relative risk reduction of 2.8% for each % of TILs). In multivariate analysis with stage, age, node status and RD tumor cellularity, TILs in the post-NAC disease remained a significant predictor of RFS and OS (p=0.0008 and p=0.007, respectively). TILs tended to decrease with NAC in paired samples, although this decrease was not statistically significant (p=0.07).

Genetic alterations in the Ras/MAPK (amplifications in KRAS, BRAF, RAF1 and truncations in NF1) and cell cycle pathway (alterations in CCND1-3, CDK4, CDK6, CCNE1, RB, AURKA and CDKN2A) were associated with lower TILs in RD (p=0.005 and p=0.05, respectively). A significant inverse linear correlation was detected between a transcriptional signature of Ras/MAPK activation (Pratilas et al, PNAS 2009) and TILs in the RD (Spearman’s r=-0.42; p=0.00028). Total number of alterations of likely functional significance detected by tNGS showed no association with TILs, suggesting that the association of Ras/MAPK deregulation and cell cycle alterations with TILs may be a pathway-specific effect.

In TNBC cell lines, chemical inhibition of MEK transcriptionally up-regulated MHC-I and MHC-II molecules, while simultaneously down-regulating mRNA expression of the immune checkpoint inhibitor PD-L1 (MDA-231 p=0.00002, BT549 p=0.0003, and SUM159PT p=0.009). In vivo experiments confirming these associations are underway.

Conclusions: Our data suggest a strong correlation of Ras/MAPK pathway activation with immune-evasion and outcome in TNBC. With additional mechanistic understanding, rational design of clinical trials combining MEK inhibitors with PD-L1 antibodies in TNBC may be warranted.
**Title:** A phase Ib study of pembrolizumab (MK-3475) in patients with advanced triple-negative breast cancer

Rita Nanda¹, Laura Q Chow², E Claire Dees³, Raanan Berger⁴, Shilpa Gupta⁵, Ravit Geva⁶, Lajos Pusztai⁷, Marisa Dolled-Filhart⁸, Kenneth Emancipator⁹, Edward J Gonzalez⁸, Jennifer Houp⁸, Kumudu Pathiraja⁹, Vassiliki Karantza⁹, Robert Iannone⁸, Christine K Gause⁹, Johnathan D Cheng⁸ and Laurence Buisseret⁹. ¹University of Chicago, Chicago, IL; ²University of Washington, Seattle, WA; ³UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC; ⁴Sheba Medical Center, Tel Hashomer, Israel; ⁵H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL; ⁶Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; ⁷Yale School of Medicine, New Haven, CT; ⁸Merck & Co., Inc, Whitehouse Station, NJ and ⁹Institut Jules Bordet, Université Libre de Bruxelles, Bruxelles, Belgium.

**Body:**

Introduction: The PD-1 receptor-ligand pathway can be used by tumors to evade immune surveillance, thereby allowing neoplastic growth. Pembrolizumab is a highly selective, humanized IgG4/kappa isotype mAb designed to block PD-1 interaction with its ligands PD-L1 and PD-L2, thereby reactivating the immune system to eradicate tumors.

Methods: This is a multi-center, non-randomized trial of single agent MK-3475 treatment given intravenously at 10 mg/kg every 2 weeks, in patients with recurrent/metastatic triple-negative (ER, PR, and HER2 negative) breast cancer (TNBC). PD-L1 expression in tumor or stroma was required for study entry. PD-L1 status was determined by immunohistochemical analysis of patient’s tumor tissues using the Merck proprietary 22C3 antibody. Primary objectives of this study were to determine the safety, tolerability, and anti-tumor activity of MK-3475 in patients with PD-L1 positive, advanced TNBC. Secondary objectives included assessments of progression-free survival, overall survival, and response duration. Adverse events (AEs) reported in any patient receiving at least 1 dose of study treatment were monitored and graded using NCI CTCAE v. 4.0. Radiographic imaging was obtained every 8 weeks and evaluated by both investigator and an independent radiologist to assess clinical responses as defined by RECIST 1.1. This study (Clinicaltrials.gov: NCT01848834) is being conducted in conformance with Good Clinical Practices.

Results: A total of 32 female patients with a median age of 50.5 years (range 29 – 72 years) with PD-L1 positive, recurrent/metastatic TNBC were enrolled in the study. Most of these patients had received and progressed on multiple lines of therapy for advanced disease. A preliminary analysis of data collected as of 23May2014 indicates that 5 patients (15.6%) experienced at least one drug-related serious adverse event (SAE); each of 4 patients experienced one of the following: Grade 3 anemia, headache, aseptic meningitis or pyrexia, and a fifth patient experienced disseminated intravascular coagulation (DIC) with thrombocytopenia and decreased blood fibrinogen. The patient who experienced DIC died. Preliminary analysis of data collected from investigators as of 23May2014 indicates that no patient had a complete response, 16.1% of patients had a partial response, 9.7% had stable disease, and 64.5% had progressive disease. As of 23May2014, all but one of the responders, in addition to three patients with stable disease, remain on treatment.

Conclusion: This is the first report of clinical activity of an immune checkpoint inhibitor in TNBC. The preliminary results from this study suggest that single agent MK-3475 is a well-tolerated and effective treatment with significant therapeutic activity in a subset of heavily pre-treated patients with recurrent/metastatic triple-negative breast cancer.
Title: Theranostic multiparametric tests improve residual risk assessment in early luminal breast cancer

John MS Bartlett¹,⁹, Vicky S Sabine¹, Syed Haider¹, Camilla Drake¹, Cheryl Crozier¹, Cindy Q Yao¹, Cassandra L Brookes², Cornelis JH van de Velde³, Annette Hasenburg⁴, Dirk G Kieback⁵, Christos Markopoulos⁶, Luc Y Dirix⁷, Caroline Seynaeve⁸, Daniel W Rea² and Paul C Boutros¹,⁹. ¹Ontario Institute for Cancer Research, Toronto, ON, Canada; ²Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, United Kingdom; ³Leiden University Medical Center, Leiden, Netherlands; ⁴University Hospital, Freiburg, Germany; ⁵Klinikum Vest Medical Center, Marl, Germany; ⁶Athens University Medical School, Athens, Greece; ⁷St Augustinus Hospital, Antwerp, Belgium; ⁸Erasmus MC Daniel den Hoed Cancer Center, Rotterdam, Netherlands and ⁹University of Toronto, Toronto, ON, Canada.

Body: Background: Despite rapidly expanding availability of multiparametric tests which inform residual risk following adjuvant therapy for early breast cancer current approaches provide minimal information on the appropriate targeted therapy to be selected for patients at high risk of recurrence. We hypothesised that inclusion of key signalling nodes from driver molecular pathways in early breast cancer in residual risk signatures would both improve risk stratification and identify candidate theranostic targets for the next generation of clinical trials.

Methods: RNA was extracted from FFPE luminal breast cancers from the TEAM pathology study (Exemestane versus Tamoxifen-Exemestane). Gene expression analyses were performed for 29 genes mapped across key signalling nodes within the PIK3CA pathway. mRNA assessment for IHC4 (ER, PgR, HER2 and Ki67) was included in the model. Quantitative gene expression was performed using the Nanostring platform. Novel signatures were trained in a randomly selected sub-set of the TEAM pathology cohort (n=˜1700) and validated using the remaining 50% of patients (n=˜1700). Results presented represent those from the validation cohort.

Results: The IHC4-protein and IHC4-mRNA risk scores were highly correlated (Rho=0.72, p=4.12x10-265), suggesting the mRNA abundance-based classifier is able to serve as a good substitute for the protein-based model.

A gene signature including IHC4 markers assessed by mRNA performed significantly better (AUC 0.70 vs 0.66) than conventional IHC4. A gene signature including 4 signalling modules from the PIK3CA pathway significantly outperformed both IHC4 and the 4 gene (ER, PgR, HER2, Ki67) classifier (AUC 0.75; p = 3.23x10-7 vs IHC4 and 1.39x10-3 vs "IHC4mRNA").

Conclusions: Inclusion of PIK3CA signalling modules identified key genes/nodes which are linked to early relapse in luminal breast cancer and provided a significantly improvement in risk classification when compared to a currently validated multiparameter test.
**Title:** The FERGI phase II study of the PI3K inhibitor pictilisib (GDC-0941) plus fulvestrant vs fulvestrant plus placebo in patients with ER+, aromatase inhibitor (AI)-resistant advanced or metastatic breast cancer – Part I results

Ian Krop, Stephen Johnston, Ingrid A Mayer, Maura Dickler, Vinod Ganju, Andres Forero-Torres, Bohuslav Melichar, Serafin Morales, Richard de Boer, Steven Gendreau, Mika Derynck, Mark Lackner, Jill Spoerke, Ru-Fang Yeh, Gallia Levy, Vivian Ng, Carol O'Brien, Heidi Savage, Yuanyuan Xiao, Timothy Wilson, Soo Chin Lee, Katarina Petrakova, Susanne Vallentin, Denise Yardley, Matthew Ellis, Martine Piccart, Edith A Perez, Eric Winer and Peter Schmid. Dana-Farber Cancer Institute, Boston, MA; Royal Marsden Hospital, London, United Kingdom; Vanderbilt-Ingram Cancer Center, Nashville, TN; Memorial Sloan Kettering Cancer Center, NY, NY; Peninsula Oncology Centre, Melbourne, Australia; University of Alabama, Birmingham, AL; Palacky University Medical School and Teaching Hospital, Olomouc, Czech Republic; Hospital Arnaud de Vilanova, Lleida, Spain; Royal Melbourne Hospital, Parkville, Australia; Genentech, San Francisco, CA; National University Hospital, Singapore, Singapore, Singapore; Masaryk Memorial Cancer Institute, Brno, Czech Republic; Herlev University Hospital, Herlev, Denmark; Sarah Cannon Research Institute, Nashville, TN; Washington University School of Medicine, St Louis, MO; Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium; Mayo Clinic, Jacksonville, FL and Barts Cancer Institute, Queen Mary University London, London, United Kingdom.

**Body: Background:** Preclinical and clinical data indicate a key role for the PI3-kinase (PI3K) pathway in the pathogenesis of resistance to endocrine therapies in hormone receptor-positive (HR) breast cancer (BC) and suggest that combining PI3K inhibitors with endocrine therapy may partially overcome this resistance. FERGI is the first randomized Phase II study testing pictilisib (GDC-0941), a PI3K inhibitor, in combination with fulvestrant to evaluate this hypothesis in MBC patients with and without PIK3CA-mutant tumors.

**Methods:** 168 post-menopausal pts with ER-positive, HER2-negative MBC were randomized (1:1) to receive fulvestrant with either pictilisib 340 mg QD (n=89, “combination” arm) or matching placebo (n=79, “control” arm). To be eligible, pts had to have relapsed during or within 6 mos of completing adjuvant AI treatment or have progressed on an AI for MBC. Pts were stratified based on tumor PIK3CA mutation status, resistance to prior AI therapy and presence of measurable disease. The primary endpoint was PFS by investigator assessment in the intent-to-treat (ITT) group and in pts with centrally confirmed PIK3CA-mutant tumors. The primary analysis was based on a 6 mo median duration follow up.

**Results:** Baseline disease and prior treatment characteristics were similar between study arms. Observed treatment-emergent AEs were consistent with those previously described for single agent pictilisib and fulvestrant (primary toxicities were rash and GI disorders). In the ITT population (84 events) the median PFS (mPFS) was 6.2 mo in the combination arm vs 3.8 months for the control arm (HR, 0.77; 95% CI, 0.50-1.19). For pts with PIK3CA-mutant tumors (37 events), mPFS was 6.2 mo in the combination arm vs 5.1 mo in the control arm (HR, 0.92; 95% CI, 0.48-1.76). For pts without a detectable PIK3CA mutant tumor (43 events), mPFS was 5.8 months in the combination arm vs 3.6 months in the control arm (HR, 0.64; 95% CI, 0.35-1.17). Exploratory post-hoc subgroup analysis suggested improvement in PFS in pts with ER+ and PR+ tumors (centrally confirmed) treated with pictilisib plus fulvestrant. In the ER+/PR+ subgroup (57 events) mPFS was 7.2 mo in the combination arm vs 3.7 mo in the control arm (HR, 0.46; 95% CI, 0.27 to 0.78). This improvement was independent of tumor PIK3CA mutation status. Multivariate analysis suggests that this treatment effect in pts with ER+/PR+ tumors is maintained after adjusting for possible baseline imbalances. A similar analysis on pts with luminal A tumors (per PAM50 analysis) was also consistent with the findings in pts ER+/PR+ disease.

**Conclusions:** This is the first report of a blinded, randomized clinical study evaluating a PI3K inhibitor in pts with MBC. In the ITT population, the addition of pictilisib to fulvestrant was associated with a mPFS improvement of 3.8 mo to 6.2 mo. Exploratory subgroup analyses suggested in pts with ER+/PR+ tumors are more likely to derive benefit from the addition of pictilisib to fulvestrant irrespective of PIK3CA mutation status, though the subgroup analyses are limited by the sample size. Additional biomarker analyses will be reported.
**Title:** Preoperative window of opportunity study of the PI3K inhibitor pictilisib (GDC-0941) plus anastrozole vs anastrozole alone in patients with ER+, HER2-negative operable breast cancer (OPPORTUNE study)

Peter Schmid¹, Sarah E Pinder², Duncan Wheatley³, Jane Macaskill⁴, Charles Zammit⁵, Jennifer Hu⁶, Robert Price⁷, Nigel Bundred⁸, Sirwan Hadad⁹, Alice Shia¹, Louise Lim¹, Shah-Jalal Sarker¹, Patrycja Gazinska², Natalie Woodman⁶, Darren Korbie¹⁰, Matt Trau¹⁰, Paul Mainwaring¹¹, Peter Parker¹², Arnie Purushotham² and Alastair M Thompson¹³.

¹Barts Cancer Institute, Charterhouse Square, London, United Kingdom; ²Guy's and St Thomas' Hospital, London, United Kingdom; ³Royal Cornwall Hospital, Cornwall, United Kingdom; ⁴Ninewells Hospital, Dundee, United Kingdom; ⁵Brighton and Sussex University Hospitals NHS Trust, Brighton, United Kingdom; ⁶St Barts Hospital, London, United Kingdom; ⁷King's College Hospital, London, United Kingdom; ⁸University Hospital South Manchester, Manchester, United Kingdom; ⁹Royal Hallamshire Hospital, Sheffield, United Kingdom; ¹⁰Australian Institute for Bioengineering and Nano-technology, St Lucia, Australia; ¹¹ICON Cancer Care, Brisbane, Australia; ¹²Kings College London, London, United Kingdom and ¹³MD Anderson Cancer Centre, Texas, TX.

**Body: Background:** Preclinical and clinical data support a key role for the PI3K pathway in resistance to endocrine therapy in patients with ER+ breast cancer and suggest that combining PI3K inhibitors with endocrine therapy may overcome resistance. Short-term preoperative window of opportunity (WOO) studies are a validated strategy for novel treatments to provide proof-of-concept and define the most appropriate patient population by directly assessing treatment effects in tumour tissue before and after treatment. This is the first WOO study with the PI3K inhibitor pictilisib (GDC-0941) in combination with anastrozole (ANA).

**Methods:** 73 postmenopausal patients (pts) have been randomized (2:1 in favour of the combination) to receive 2-week preoperative treatment with ANA plus pictilisib (n=50, "ANA+PIC" arm) or ANA alone (n=23, "ANA" arm). Pts had newly diagnosed, operable, ER+, HER2-negative breast cancer of ≥ 1 cm size. Pts receiving HRT were excluded. Treatment effects and correlative studies were assessed using FFPE and frozen tumour biopsies taken before and after 14 days of study treatment. The primary endpoint was inhibition of tumour-cell proliferation, as measured by change in Ki67 expression, determined centrally by 2 investigators. Secondary endpoints include induction of apoptosis (Caspase3) and safety. Comprehensive biomarkers analyses include targeted NGS of a comprehensive cancer panel of >400 genes, copy number analyses, and pre- and post-treatment reverse-phase protein arrays (RPPA) and RNA profiling.

**Results:** Baseline (BL) disease characteristics were similar between both study arms. PAM50 analysis showed that 53% and 47% of tumors were Luminal (Lum) A and B, respectively. 65% of tumors had >14% Ki67-positive cells. Observed treatment-emergent AEs were consistent with those previously described for single-agent pictilisib and anastrozole. Mean post-treatment percentage reduction of Ki67 was 84% (95% CI, 75%-89%) for ANA+PIC and 72% (54%-87%) for ANA. Ki67-response (≥50% drop in % of Ki67+ cells) was 86% for ANA+PIC and 60% for ANA. By using the definition that pts with a natural logarithm of %Ki67+ cells of ≤ 1 or 1-2 have a day 15 anti-proliferative response, 93% [ln(ki67): <1, 46%; 1-2, 46%] of ANA+PIC were responders compared with 60% [<1, 47%; 1-2, 13%] of ANA-treated pts (p = 0.01). Preplanned subgroup analyses showed a significant interaction of response to ANA+PIC with molecular subtype and Ki67 levels. Patients with LumB tumors or high BL Ki67 (>14%) had a higher Ki67 response with ANA+PIC compared to ANA (LumB, 83% vs 38%; Ki67>14%, 94% vs 55%), whereas Ki67 response was similar for both treatments for LumA tumors (ANA, 75%; ANA+PIC, 73%) or tumors with low BL Ki67. Mean post-treatment % reduction of Ki67 in LumB tumors was 87% (95% CI, 49%-96%) for ANA+PIC and 56% (16%-77%) for ANA (p=0.03).

Additional data on apoptosis and comprehensive pre- and post-treatment biomarkers analyses will be presented.

**Conclusions:** This first report of a preoperative WOO study evaluating a PI3K inhibitor in early breast cancer demonstrated addition of pictilisib to ANA was associated with increased anti-proliferative response over single-agent ANA.
Title: Comprehensive molecular characterization of invasive lobular breast tumors

Giovanni Ciriello¹, Michael L Gatza², Katherine A Hoadley², Hailei Zhang³, Suhn K Rhie⁴, Reanne Bowiby⁵, Matthew D Wilkerson², Cyriac Kandoth¹, Michael McLellan⁶, Andrew Cherniack³, Peter W Laird⁴, Chris Sander¹, Tari A King¹ and Charles M Perou².

¹Memorial Sloan Kettering Cancer Center, New York, NY; ²University of North Carolina, Chapel Hill, NC; ³Broad Institute of MIT and Harvard, Cambridge, MA; ⁴University of Southern California, Los Angeles, CA; ⁵British Columbia Cancer Agency and ⁶Washington University, St Louis, MO.

Body: Invasive lobular breast cancer (ILC) is the second most common histological subtype of breast cancer accounting for 10-15% of invasive breast tumors. ILC is typically ER+ and beyond the known mutation and/or loss of E-cadherin function, which contributes to a highly discohesive morphology, little is known about the additional mechanisms driving ILC tumorigenesis, or alterations that differentiate ILC from invasive ductal carcinomas (IDC).

Methods
A dataset of 817 breast tumors from the TCGA Project, including 490 IDC, 127 ILC and 88 samples with a mixed IDC-ILC histology, were profiled on six genomic platforms to develop a comprehensive atlas of mutational, epigenetic, transcriptional and proteomic data. Integrative genomic analyses, both supervised and unsupervised, of ILC tumors and across histological subtypes were performed to identify genomic drivers of ILC oncogenesis.

Results
Comprehensive multi-platform analyses identified distinct molecular events associated with ILC tumors. As expected, lack of E-cadherin protein, as determined by Reverse Phase Protein Array (RPPA), and CDH1 mRNA expression was uniformly observed in ILC cases associated with distinct alterations targeting CDH1. In addition to previously reported CDH1 and PIK3CA mutations, we identified a number of novel ILC-enriched recurrent mutations targeting PTEN, RUNX1, TBX3, and FOXA1. An increased incidence of PTEN inactivating events, both mutations and copy number changes, were identified in ILC (13%) compared to IDC ER+ (7%), which corresponded with altered PTEN protein expression. These alterations were largely mutually exclusive with PIK3CA mutations and correlate with increased Akt activation as evident by increased Akt phosphorylation (pS473 and pT308), thus identifying a potential therapeutic opportunity for ILC patients.

GATA3 signaling, which regulates epithelial cell differentiation, is frequently altered in luminal/ER+ breast cancers. Our analyses determined GATA3 mutations are more frequent in IDC luminal tumors as compared to ILC (19 % vs 5%). ILC luminal tumors show significantly lower GATA3 protein expression, but a higher frequency of mutations in FOXA1 (9% vs 2% in Luminal IDC), a transcription factor required to promote ER transcriptional programs. Within ILC tumors, FOXA1 mutations were found to cluster into a specific region of the Forkhead (FK) DNA binding domain. A broader analysis of FOXA1 mutations in breast and prostate cancer confirm two specific hotspots in the FK domain and the C-terminal transactivation domain. Interestingly, these mutational classes are associated with distinct transcriptional changes suggesting different functional effects.

Finally, mRNA-seq analyses identified three robust molecular subclasses that are characterized by distinct genetic, genomic and proteomic patterns, including an increased immune-related group (Class 2), as well as differences in prognosis.

Conclusions
In this study, we developed a comprehensive atlas of genomic alterations that reveals key molecular differences differentiating ILC (FOXA1) from IDC (GATA3) tumorigenesis, a potential therapeutic target for ILC (Akt), and novel ILC subclasses based on underlying biological events. These findings provide further insight into the molecular heterogeneity of ER+ breast cancer.

Body: Background:
Invasive lobular breast cancer (ILC) is the second most common histological subtype of breast cancer, is mostly estrogen receptor-positive (ER+) and has distinct clinico-pathological features when compared to ER+ invasive ductal carcinoma (IDC). In this study, we aimed to characterize the genomic alterations defining ILC in a large cohort of ILC patients with long-term follow up (FU).

Material & methods:
In 499 centrally histologically confirmed ILC patients (median FU= 9.8 years) we analyzed mutational data gathered from targeted sequencing of 360 cancer genes at an average coverage of 106X (alignment done with BWA, substitutions and indels –further referred to as mutations- called with Caveman and Pindel). Matched normal DNA was available for 242 patients. Genome-wide copy number (CN) data were available for 178 patients. E-cadherin (CDH1) and beta-catenin (CTNNB1) stains were carried out using the DakoTM antibodies. Invasive disease free survival (IDFS) was considered as primary survival endpoint.

Results:
A median of 6 [range:0-38] non-silent mutations was identified across the primary tumors of all patients. The most frequently mutated genes (>3%) are listed in Table 1. Of those, CDH1, PIK3CA, TBX3, FOXA1 and the chromatin-related genes MLL2, MLL3, ARID1A and ARID1B were more frequently mutated in our ER+/HER2- ILC (n= 451) compared to the ER+/HER2- IDC (n=266) from The Cancer Genome Atlas, whereas GATA3, TP53 and MAP3K1 were less frequently mutated.

Samples with a CDH1 mutation were associated with changes at the protein level: 97.5% displayed a complete loss of the protein, associated with cytoplasmic staining for CTNNB1, compared to only 63% of the CDH1 non-mutated tumors. CDH1 mutated tumors were further characterized by increased mutational frequencies of the ERBB-genes: 15.4% for the CDH1 mutated tumors versus 3% in the CDH1 non-mutated tumors, most of those mutations being described in the literature as activating the pathway. Almost all tumors (97%) with CN data had a heterozygous loss of CDH1.

The special alveolar, solid and trabecular lobular histotypes were associated with specific CN alterations and mutations. Tumors with mutated ARID1A or ATM were associated with worse IDFS at the univariate level and ARID1A remained significant in a multivariate analysis including standard parameters (HR =2.07, p=0.003). At the CN level, ATM and ARID1A losses, as well as HER2 and VEGFA gains/amplifications were associated with decreased IDFS, all but ARID1A holding significance at the multivariate level (HR_HER2=2.41, HR_VEGFA= 1.99, HR_ATM= 1.79, all p<0.05).

Conclusion:
This is the first and largest study to our knowledge to report genomic alterations present in ILC and their association with survival. This work therefore opens new avenues for a better understanding of the disease and its clinical management.

Title: Survival advantage of anastrozole compared to tamoxifen for lobular breast cancer in the ABCSG-8 study

Michael Knauer¹, Christine Gruber², Otto Dietze³, Richard Greil³, Herbert Stöger⁴, Margaretha Rudas⁵, Zsuzsanna Bago-Horvath⁵, Brigitte Mlineritsch³, Werner Kwasny⁶, Christian Singer⁵, Peter Dubsky⁵, Raimund Jakesz⁵, Florian Fitzal², Günther Steger⁵, Rupert Bartsch⁶, Martin Filipits³, Christian Fesl⁷ and Michael Gnant⁵.

Body: Introduction:
Invasive lobular cancer (ILC) is the second most common histological type of breast cancer, appearing to have a biology distinct from ductal cancer (IDC). In the first 5 years, the prognosis of ILC seems to be more favourable compared to IDC. The aim of this study was to investigate the differences in benefit from adjuvant Tamoxifen (Tam) and Anastrozole (Ana) for these histologic subtypes.

Patients and Methods:
The ABCSG-8 (Austrian Breast and Colorectal Cancer Study Group 8) study was a randomized phase III clinical trial (n=3,714) in hormone receptor-positive cancer addressing a sequence strategy with 3 years of Ana after 2 years of Tam in comparison with 5 years of Tam in a low- to intermediate-risk group (Grade 1/2) of postmenopausal patients not receiving adjuvant chemotherapy. Univariate and multivariate comparisons for overall (OS) and disease-free survival (DFS) between endocrine treatments were conducted per subgroup with respect to histology (ductal or lobular). Multivariate Cox analysis included endocrine treatment, histology and their interaction ± additional covariates (age, T-stage, N-stage, grade, ER, PR). For the time-to-event analyses, starting point for all patients was two years after randomization, i.e. when treatment changed from Tamoxifen to Anastrozole on the experimental arm. To avoid crossover effects for post-study treatment, the total time for this analysis is 3 years.

Results:
The 3-year OS hazard ratio (HR) for Anastrozole versus Tamoxifen in ILC (n=694) was 0.24 (0.08-0.70) vs. IDC (n=2,739) HR 1.08 (0.75-1.58). In multivariate analysis, HR for ILC was 0.23 (0.08-0.68) vs. 1.02 (0.70-1.49) for IDC. The test for interaction of treatment and histology was significant (p=0.01). In ILC, no other clinico-pathologic factor was significantly associated with survival differences compared to IDC, where age, T- and N-stage maintained significance. In the models for DFS, our preliminary analysis after 3-year follow-up did not show significant variations in treatment effect according to histology.

Discussion:
The magnitude of survival benefit from adjuvant Anastrozole vs. Tamoxifen varies by histology in this large phase III randomized trial. A significant reduction in risk of death occurs only in patients with lobular cancer compared to ductal cancer after only 3 years of follow-up. An updated analysis with additional follow-up will be available at presentation.

Body: Background: Anthracycline/taxane based regimen are standard of care for neoadjuvant therapy in breast cancer. A reverse sequence of taxanes followed by anthracyclines was suggested to achieve higher pCR rates (H.Earl, Lancet Oncol 2014). Dual HER2 blockade was shown to be superior to trastuzumab alone increasing the pCR rate by 20%. Nab-paclitaxel (nP) is a solvent-free formulation of paclitaxel (P) encapsulated in albumin which might further improve the pCR rate in breast cancer patients receiving neoadjuvant treatment and cause lower toxicity.

Methods: In the GeparSepto study (NCT01583426) patients were randomized to either nP (125 mg/m\textsuperscript{2}) q1w or P (80mg/m\textsuperscript{2}) q1w for 12 weeks followed by 4 cycles of conventionally dosed EC (E, epirubicin 90mg/m\textsuperscript{2}; C, cyclophosphamide 600 mg/m\textsuperscript{2}) q3w. The primary objective is to compare the pathological complete response rate (pCR, ypT0 ypN0). Further objectives are to compare the pCR rate in predefined subgroups, pCR by other definitions, clinical response rate, rate of breast conserving surgery and toxicity and compliance. Patients with untreated, histologically confirmed uni- or bilateral, cT2- cT4d carcinoma, and no clinically relevant cardiovascular and other co-morbidities were included. HER2\textsuperscript{+} patients received trastuzumab (loading dose 8mg/kg; 6 mg/kg) plus pertuzumab (loading dose 840 mg; 420 mg) q3w concomitantly. HER2, estrogen receptor, progesterone receptor, Ki67 and SPARC status were centrally assessed prior to randomization for stratification. To increase the pCR rate from 33% with P to 41% with nP, corresponding to an odds ratio of 1.41 with an alpha of 0.05 and a power of 80%, 1200 patients would be needed. A window-of opportunity study was integrated to investigate response to anti-HER2 treatment without chemotherapy, HER2\textsuperscript{+} patients were randomized to receive 6 weeks of either trastuzumab, pertuzumab or the combination with biomaterial collection at the start and the end of the window.

Results: A total of 1204/1229 (window study n=71) recruited patients (7/2012 - 12/2013) from 69 German centers were evaluable, 606 receiving nP. Baseline characteristics are well balanced; median age was 49/50 years (P/nP), 33/33% of the patients presented with HER2\textsuperscript{+} tumors, 23/23% triple negative breast cancer TNBC (ER and PR <1 %), 87/85% ductal invasive, 56/52% G3 tumors; Ki67>20% 69/69%; SPARC positive 15.7/16%. 265 patients reported SAEs (119 P/146 nP) and 4 died on study (1 P: cardiac decompensation; 3 nP: accident at home, multiorgan failure, sepsis during EC). The pCR rate (ypT0 ypN0) is 29% with P and 38% with nP, OR 1.5; p<0.01.

Conclusions: GeparSepto showed that the pCR rate is significantly higher with nab-paclitaxel compared to solvent-based paclitaxel given weekly before anthracycline based chemotherapy. Subgroupanalyses and 2ndary endpoints will be presented at the meeting.

The trial was financially supported by Roche and Celgene. The window-substudy was funded within the EU-FP7 project RESPONSIFY No 278659.
Title: The TNT trial: A randomized phase III trial of carboplatin (C) compared with docetaxel (D) for patients with metastatic or recurrent locally advanced triple negative or BRCA1/2 breast cancer (CRUK/07/012)

Body: Introduction:
Subgroups within sporadic triple negative breast cancers (TNBCs) appear to share impaired DNA damage response mechanisms with BRCA1/2 mutation-associated breast cancers. This has been hypothesised to confer particular sensitivity to DNA-damaging platinum chemotherapy. The TNT trial, a randomized phase III trial in women with metastatic or recurrent locally advanced TNBC or BRCA1/2 mutation-associated breast cancer, aimed to test this hypothesis and examine treatment effect in biological subgroups.

Patients & Methods:
Eligible patients had either ER-, PR-, HER2- breast cancer or were known BRCA1/2 carriers (any ER/PR/HER2). Patients were randomized (1:1) to receive either C (AUC 6 q3wk) or D (100mg/m2 q3wk) for 6-8 cycles or until disease progression if sooner and could cross over to the alternative treatment on confirmed progression. Ineligible patients included those who had ECOG performance status >2, received adjuvant taxane therapy in the last 12 mths, any previous treatment with a platinum chemotherapy, or previous non-anthracycline chemotherapy for metastatic disease.

For consenting patients a blood sample and archived tissue samples were obtained for BRCA1/2 genotyping and central biomarker analysis (primary tumour, lymph nodes and recurrent tumour biopsy if available) of subtypes within TNBC and biomarkers of DNA repair deficiency.

The primary endpoint was RECIST objective tumour response up to cycle 6 of randomised treatment. Secondary endpoints included toxicity, progression free survival (PFS), time to progression and overall survival.

TNT aimed to detect a 15% improvement in ORR with C compared to D, with planned target sample size range of 370-450 depending on assumed ORR in D patients (2-sided \(\alpha=0.05\), power=90%). 376 (188 C, 188 D) were recruited from 74 UK centres between Apr 08 and Mar 14.

Results:
A snapshot of the data was taken on 30/5/14 at which point 336 (89.4%) patients had experienced a PFS event, with overall median PFS time of 4.4 mths. Median age of patients was 55 yrs (IQR 48-63). 366/376 (97%) patients had TNBC of whom 18 were also known BRCA1/2 mutation carriers, with the remaining 10 patients receptor +ve and BRCA1/2 carriers. 338/376 (90%) had metastatic and 38/376 (10%) recurrent locally advanced disease. 53% had liver or lung metastases affecting the parenchyma and 34% had received previous adjuvant taxane therapy. Median time from initial diagnosis to entering TNT was 2.2 yrs (IQR 1.5-3.5). Primary tumour tissue has currently been received for 277 patients, blood from 286 patients and recurrent tumour tissue from 85 patients.

Discussion:
TNT will report evidence on the activity of single agent platinum chemotherapy compared with single agent taxane in patients with TNBC and BRCA1/2 associated breast cancer. Correlative analyses of BRCA1/2 mutation status, subtypes and DNA repair
biomarkers will also be reported. TNT will be the first randomised trial to report the activity of platinum compared with standard chemotherapy within TNBC subtypes and in relation to BRCA1/2 mutation status and DNA repair biomarkers. Safety, tolerability and response to crossover treatment will also be presented.

Body: Background

NSABP B-36 was originally designed as a 2X2 factorial randomized study to compare 6 cycles of FEC-100 with 4 cycles of standard AC with or without celecoxib in pts with node-negative breast cancer. The rationale for the trial was based on observations from other adjuvant trials suggesting that longer duration of anthracycline-based therapy may result in improved outcomes and also on accumulating evidence that prostaglandins may contribute to the malignant phenotype in breast cancer. The trial opened in May 2004 but random assignment to celecoxib v placebo was terminated in December 2004 (after 327 pts were enrolled) because of concerns for increased risk of cardiovascular disease with the use of COX-2 inhibitors. The trial continued as a two-arm study and completed accrual in July 2008. The primary endpoint of disease-free survival (DFS), and secondary endpoints of overall survival (OS), recurrence-free interval (RFI), distant recurrence-free interval (DRFI), and adverse events comparing FEC-100 and AC are reported here. Analyses of quality of life indicators will be reported separately.

Methods

2,722 pts with T1-3, pN0 breast cancer were randomly assigned to either adriamycin 60 mg/m2 and cyclophosphamide 600mg/m2 every 21 days for 4 cycles (n=1361) or 5-FU 500mg/m2, epirubicin 100 mg/m2 and cyclophosphamide 500 mg/m2 every 21 days for 6 cycles (n=1361). Hormone- receptor positive pts were to receive physician's choice of hormonal therapy for a minimum of 5 yrs. Trastuzumab for HER2-positive pts was at investigator's discretion but was not to begin for >3 weeks after the last dose of chemotherapy. All women treated with lumpectomy were to receive breast radiotherapy; post-mastectomy chest wall radiotherapy was at physician's discretion. The differences in DFS (OS, RFI, and DRFI) between two treatment arms were assessed by log-rank test stratified by hormone receptor status and type of surgery.

Results

Median follow-up is 82.8 months. Pt and tumor characteristics were equally distributed between the two groups (<50 years old: 40%, lumpectomy: 68%, and hormone positivity: 65%). Overall, Grade 3 and 4 expected toxicities were more frequent in the FEC arm. Combined Grade 3/4 toxicities reaching statistical significance with a difference of 3% or more between AC and FEC arms included fatigue 3.55% v 8.45%, febrile neutropenia 3.70% v 9.42%, and thrombocytopenia 0.74% v 4.41%, respectively. While on treatment, Grade 3 left ventricular systolic dysfunction occurred in one pt in each arm. There were 2 toxicity deaths on AC and 5 on the FEC arm. Primary and secondary endpoint analyses at 8 ys did not reveal any significant differences in DFS, OS, RFI, or DRFI.

Conclusions
Six cycles of the FEC-100 regimen did not result in any efficacy advantage over 4 cycles of standard AC in node-negative breast cancer pts. As anticipated, the FEC-100 regimen resulted in greater toxicity.

Title: Ten year update of E1199: Phase III study of doxorubicin-cyclophosphamide followed by paclitaxel or docetaxel given every 3 weeks or weekly in patients with axillary node-positive or high-risk node-negative breast cancer

Body: Background: We had previously reported after a median followup of 5.3 years that disease free survival (DFS) was improved with either adjuvant weekly paclitaxel (hazard ratio [HR] 0.73, p=0.0006) or every 3 week docetaxel (HR 0.77, p=0.02) compared with every 3 week paclitaxel (N Eng J Med 2008; 358; 1663), and that obesity and black race were independently associated with inferior outcomes in estrogen receptor (ER)-positive disease after a longer followup (Cancer 2012: 118: 5937 & JNCI 2012; 104: 406). We now report updated results after a median followup of 12.1 years.

Methods: Eligibility included axillary lymph node positive or high-risk (tumor at least 2 cm) node-negative breast cancer. All patients received 4 cycles of AC (doxorubicin 60 mg/m2 and cyclophosphamide 600 mg/m2) every 3 weeks, followed by either: (1) paclitaxel 175 mg/m2 every 3 weeks x 4 (P3), (2) paclitaxel 80 mg/m2 weekly x 12 (P1), (3) docetaxel 100 mg/m2 every 3 weeks x 4 (D3), or (4) docetaxel 35 mg/m2 weekly x 12 (D1). Patients with ER-positive breast cancer also received endocrine therapy for at least 5 years, including either tamoxifen and/or an aromatase inhibitor. The primary comparisons included taxane (P vs. D) and schedule (every 3 weeks vs. weekly), and the primary endpoint was DFS, defined as local, regional, and/or distant relapse, second primary breast cancer, or death without recurrence.

Results: A total of 4954 eligible patients were accrued between October 1999 and January 2002. At the time of this analysis, 90% of surviving patients were followed for at least 10 years, and there were substantially more DFS events (1639 vs. 1048) and deaths (1283 vs. 686) than the original report. For the primary comparison, there remains no significant difference in DFS by taxane (p=0.33) or schedule (p=0.88), although there was a significant interaction between taxane and schedule (p<0.007). When comparing the standard arm (P3) to the other arms (with a hazard ratio [HR] < 1 favoring the experimental arms using a stratified Cox model), the HRs for DFS were 0.84 (p = 0.011) for arm P1 and 0.79 (p=0.001) for arm D3 arm, and for overall survival (OS) were 0.87 (p=0.09) and 0.86 (p=0.054), respectively. When evaluated by subtypes in exploratory analyses, the P1 arm (but not the D3 arm) was associated with improved DFS (HR 0.69, p=0.01) and OS (HR 0.69, p=0.019) in the 1025 patients with triple negative breast cancer (TNBC), and the D3 arm (but not P1 arm) was associated with improved DFS (HR 0.76, p=0.004) but not OS (HR 0.87, p=0.20) in the 2785 patients with ER-positive, HER2-negative/unknown breast cancer (ERBC). In ERBC but not other subtypes, black race (HR 1.60, p=0.002) and obesity (HR 1.23, p=0.009) were associated with inferior OS, and obesity was associated with a higher recurrence risk between 3-8 years after diagnosis.

Conclusions: Improvements in DFS observed at 10 years for the P1 and D3 arms compared with the P3 arm are qualitatively similar but quantitatively less than at 5 years, and the effects on OS are marginal in the overall population. The relative effectiveness of weekly paclitaxel and every 3 week docetaxel may vary by subtype.
Background: Although approximately 50% of newly diagnosed breast cancers arise in women above 65 years old they are underrepresented in clinical trials. The ICE study was designed to investigate if a mono-chemotherapy with capecitabine in addition to the third generation bisphosphonate ibandronate will improve the outcome compared to ibandronate alone in elderly breast cancer patients with medium and high risk primary breast cancer not suitable for standard chemotherapy.

Methods: This is a prospective, multi-center, controlled, open-label, randomized phase III trial. Female patients ≥ 65 years with unilateral or bilateral breast cancer who are either node-positive or high-risk node-negative (tumor size ≥ 2 cm, grade >1, and/or ER-and PR-negative); and a Charlson Comorbidity Index (CMI) ≤ 2 received either ibandronate alone for 2 years, 50 mg p.o. daily alternatively 6 mg i.v. every 4 weeks or the same ibandronate regimen together with capecitabine 2000 mg/m² on day 1 – 14 q day 22 for 6 cycles to be started within 6 months after axillary dissection. Patients with hormone-sensitive disease received an endocrine therapy according to guidelines. The primary objective is disease-free survival. A total of 1,394 patients were needed (5-year DFS improvement from 65% with ibandronate to 71.5% with ibandronate/capecitabine; \( \alpha = 0.05, \beta = 80\% \)) and we expected 497 events during a median 5 year follow up.

Results: Between 06/2004 and 08/2008, 1409 patients were randomized to ibandronate (N=702) or ibandronate/capecitabine (N=668) in 172 German centers, of whom 1380 patients started treatment (689 and 691 respectively). Median age was 71 (range 74-80) years; 58.6% of patients had a CMI≤1, 48.2% had N+, 35.2% grade 3, and 19.2% had ER/PgR negative disease. 83.8% of patients received all 6 capecitabine cycles. Capecitabine grade 3/4 toxicities were <2% except hand-foot-syndrome (6.8%). 3 patients died in relation with capecitabine treatment. Final DFS analysis will be presented at the meeting.

Conclusion: CALGB 49907 showed that AC or CMF was superior to capecitabine in patients aged ≥65 years but was associated with twice as many moderate to severe toxic effects (64% vs 33%) (Muss H et al, NEJM 2012). The ICE study will provide evidence if capecitabine monotherapy is as active as adjuvant treatment and if it might be an option for frail and/or elderly patients where standard chemotherapy is considered to be too toxic.
Title: Intrinsic subtypes, PIK3CA mutation, and the degree of benefit from adjuvant trastuzumab in NSABP trial B-31

Soonmyung Paik\(^1\), Katherine L Pogue-Geile\(^1\), Nan Song\(^1\), Patrick G Gavin\(^1\) and Seong-Rim Kim\(^1\). \(^1\)NSABP, Pittsburgh, PA.

Body: Purpose: Considerable molecular heterogeneity exists among HER2-positive breast cancer regarding gene expression and mutation profiling. Evidence from preclinical, clinical neoadjuvant, and metastatic clinical trials suggested PIK3CA mutational status and PAM50 intrinsic subtype of a tumor were markers of response to anti-HER2 therapies. We evaluated the predictive value of these two biomarkers in the adjuvant setting using archived tumor blocks from NSABP trial B-31.

Methods: Expression data for 49 genes using the nCounter platform was used to generate PAM50 intrinsic subtypes for 1,578 archived tumor blocks from B-31. Five PIK3CA hotspot mutations were examined by mass spectrometry of the primer extension products in a randomly selected subset (N=671). We examined the heterogeneity of trastuzumab treatment effect across different subsets defined by each marker using Cox regression and disease free survival as the endpoint.

Results: 741/1578 (47.0%) tumors were classified as HER2E subtype; and 166/671 (24.7%) had PIK3CA mutations. Hazard ratios (HR) for trastuzumab in HER2E and other subtypes were 0.44 (95%CI: 0.34-0.58, p<0.001) and 0.47 (95% CI: 0.35-0.62, p<0.001), respectively (interaction p=0.67). HRs for trastuzumab in PIK3CA wild type and mutated were 0.51 (95%CI: 0.37-0.71, p<0.001) and 0.44 (95%CI: 0.24-0.82, p=0.009), respectively (interaction p=0.64).

Conclusion: Unlike results seen in the metastatic and neoadjuvant clinical trials, PIK3CA and PAM50 intrinsic subtypes were not biomarkers for differential response to trastuzumab in NSABP B-31. These data suggest that results from the metastatic and neoadjuvant setting may not be always applicable to the adjuvant setting.

Title: Mutational analysis of CALGB 40601 (Alliance), a neoadjuvant phase III trial of weekly paclitaxel (T) and trastuzumab (H) with or without lapatinib (L) for HER2-positive breast cancer

Katherine A Hoadley¹, William T Barry², Brandelyn N Pitcher³, Joel S Parker¹, Matthew D Wilkerson¹, William Irvin, Jr¹, Norah Lynn Henry³, Sara M Tolaney⁴, Chau Dang⁵, Ian E Krop⁶, Donald A Berry⁶, Elaine R Mardis⁹, Charles M Perou¹, Eric P Winer⁶, Clifford A Hudis⁷ and Lisa A Carey¹. ¹University of North Carolina, Chapel Hill, NC; ²Alliance Statistics and Data Center, Dana-Farber Cancer Institute, Boston, MA; ³Alliance Statistics and Data Center, Duke University, Durham, NC; ⁴Bon Secours Cancer Institute, Midlothian, VA; ⁵University of Michigan, Ann Arbor, MI; ⁶Dana-Farber Cancer Institute, Boston, MA; ⁷Memorial Sloan Kettering Cancer Center, New York, NY; ⁸Alliance Statistics and Data Center, MD Anderson Cancer Center, Houston, TX and ⁹Genome Institute, Washington University School of Medicine, St Louis, MO.

Body: Background: In CALGB 40601, the HER2-Enriched (HER2-E) molecular subtype had significantly higher pathologic complete response (pCR) rates regardless of treatment arm (single HER2-targeting with T+L or T+H, dual targeting with T+H+L) (Carey et al, ASCO 2014). A TP53 mutation gene expression signature was significant in a multivariable analysis as were treatment, molecular subtype, proliferation, and an immune cell genomic signature. Mutational analysis is now available for this sample set.

Methods: 265 of 305 enrolled patients (pts) had RNA sequencing (RNAseq) of pre-treatment biospecimens; 181/265 had whole exome sequencing (WES) available from tumor and matched normal blood. Somatic mutations were detected by the program UNCeqR, which integrates WES and RNAseq. We examined the association of mutations with in-breast pCR, molecular subtypes, and gene expression signatures.

Results: In this subset, there were 57 HER2-E, 58 Luminal A, 51 Luminal B, 9 Basal-like, 4 Normal-like, and 2 Claudin-low. The pCR rate was 45% (51% THL, 47% TH and 34% TL), consistent with the entire study population. TP53 was the most frequently mutated gene (56%); frequency varied by molecular subtype (Fisher p<0.0001) with the highest in the HER2-E (88%). Type of mutation also varied by molecular subtype: 34% of TP53 mutations in HER2-E pts were nonsense or frame shift mutations compared to 20% in Luminal B and 11% in Luminal A. The presence of a TP53 mutation was significantly associated with achieving pCR (59% compared to 28% in wildtype; odds ratio=3.7, p<0.0001) which did not vary by treatment arm. TP53 mutation status by WES was strongly associated with a gene-expression based predictor (AUC=0.85, p<0.001), suggesting the RNAseq-based signature could be used as a surrogate measure of genotype. PIK3CA mutations were present in 36 pts (20%); 33/36 (92%) were in exons 9 and 20. PIK3CA mutations varied moderately among subtypes and were most prevalent in Luminal B (31%) and HER2-E (25%). Rates of pCR did not vary by PIK3CA mutation status (39% vs 47% in wildtype, p=0.46). GATA3 mutations were identified in 7 pts (4 Luminal A, 3 Luminal B), but only 1 pt achieved pCR. ERBB2 mutations were found in 7 pts: 2 HER2-E, 2 Luminal A, 3 Luminal B. Two were previously identified (the lapatinib-sensitive activating mutation V777L and the lapatinib-resistant mutation L755S), both were trastuzumab resistant in experimental models (Bose et al, Cancer Discovery 2013). Consistent with these results, the V777L pt achieved pCR on the THL arm; the L755S pt did not achieve pCR on the TL arm.

Conclusions: TP53 mutation is a frequent, clinically important event in HER2-positive disease and predicts pCR to chemotherapy plus HER2-targeting. Frequency and type of mutation was dependent on molecular subtype within this clinically HER2-positive cohort. Ongoing analyses are comparing WES data between pre- and post-treatment samples as well as investigating copy number and clonality. This research is supported in part by funds from GlaxoSmithKline and grants from the Breast Cancer Research Foundation.
**Title:** 16 year long-term follow-up of the IBIS-I breast cancer prevention trial

Jack Cuzick¹, Ivana Sestak¹, Simon Cawthorn², Hisham Hamed³, Kaija Holli⁴, Anthony Howell⁵ and John F Forbes⁶. ¹Centre for Cancer Prevention, Queen Mary University, London, United Kingdom; ²North Bristol NHS Trust, Bristol, United Kingdom; ³London Bridge Hospital, London, United Kingdom; ⁴Tampere University, Tampere, Finland; ⁵Institute of Cancer Sciences, University of Manchester, Manchester, United Kingdom and ⁶School of Medicine and Public Health, University of Newcastle, Newcastle, Australia.

**Body:** Background: Several randomised clinical trials have shown the benefit of tamoxifen in healthy women to reduce their risk of breast cancer. Here, we report the blinded median 16 year follow-up of the IBIS-I trial to update the long-term prevention of breast cancer with tamoxifen treatment.

Methods: 7154 pre- and postmenopausal women were randomised to receive daily 20mg tamoxifen (N=3579) or matching placebo (N=3575) for 5 years. The primary endpoint of this analysis was the occurrence of breast cancer (invasive and ductal carcinoma in situ (DCIS)). Secondary endpoints included overall mortality, other cancers, and breast cancer specific mortality. Cox proportional hazard models were used to assess occurrence of breast cancer and survival. All statistical tests were two-sided.

Results: After a median of 16.2 years (IQR 14.4 to 17.7) of follow-up, a total of 589 breast cancers have been reported (tamoxifen: 246 (6.9%) vs. placebo: 343 (9.6%)). Tamoxifen reduced the incidence of all breast cancer overall by 29% (HR=0.71 (0.60-0.83), P<0.0001) (Figure 1). Invasive ER-positive (ER+) breast cancers were reduced by 35% (HR=0.65 (0.53-0.80), P<0.0001) (Figure 1), but no effect was seen for invasive ER-negative (ER-) breast cancers (HR=1.06 (0.71-1.58), P=0.8). A non-significant 30% reduction in DCIS was seen with tamoxifen (36 vs. 51, HR=0.70 (0.46-1.07); P=0.1). The overall risk reduction was similar in years 0-10 (HR=0.71) and years 10-20 (HR=0.70). Similar effects were seen in pre- and postmenopausal women (HR 0.71 vs. 0.71). All-cause mortality was non-significantly increased in women randomised to tamoxifen (173 vs. 158, OR=1.10 (0.88-1.38), P=0.4). The excess in deaths with tamoxifen is smaller than in the 96 month update. No differences in breast cancer mortality was seen (24 tamoxifen vs. 27 placebo; OR=0.89 (0.49-1.60), P=0.7). A non-significant increase in other cancers than breast were reported by women on tamoxifen (350 vs. 315, OR=1.12 (0.95-1.32); P=0.2). Specifically more endometrial cancers (28 vs. 17), non-melanoma skin cancers (108 vs. 85), and lung cancer (32 vs. 20) were found in those randomised to tamoxifen.

Conclusion: This updated analysis of the IBIS-I trial confirms the significant reduction in breast cancer occurrence with tamoxifen in the post-treatment follow-up period. These results indicate tamoxifen has a long-term preventive effect on invasive ER+ breast cancer in both pre- and postmenopausal women.
Title: Randomized comparison of adjuvant tamoxifen (T) plus ovarian function suppression (OFS) versus tamoxifen in premenopausal women with hormone receptor-positive (HR+) early breast cancer (BC): Analysis of the SOFT trial

Prudence A Francis¹, Meredith M Regan¹, Gini F Fleming¹, Istvan Lang¹, Eva M Ciruelos¹, Meritxell Bellet¹, Herve Bonnefoi¹, Miguel A Climent¹, Lorenzo Pavesi¹, Harold J Burstine¹, Silvana Martino¹, Nancy E Davidson¹, Charles E Geyer, Jr¹, Barbara A Walley¹, Robert E Coleman¹, Pierre Kerbrat¹, Manuela Rabaglio-Poretti¹, Alan S Coates¹, Aron Goldhirsch¹ and Richard D Gelber¹. ¹SOFT Investigators, International Breast Cancer Study Group, Breast International Group, and North American Breast Cancer Group, Bern, Switzerland.

Body: Background: The value of adding OFS to tamoxifen in premenopausal women with HR+ early BC is uncertain. SOFT was designed to determine the value of adding OFS to tamoxifen and the role of adjuvant therapy with the aromatase inhibitor exemestane (E) plus OFS in premenopausal women.

Methods: From Nov 2003 - Jan 2011, 3066 premenopausal women with HR+ BC were randomized to 5 years of tamoxifen vs tamoxifen+OFS vs exemestane+OFS. OFS was by choice of GnRH agonist triptorelin, oophorectomy or radiation. SOFT was stratified by the use of prior chemotherapy; 47% received no chemotherapy and 53% remained premenopausal after prior chemotherapy, confirmed by estradiol within 8 months of completion. The comparison of T+OFS vs T alone was the primary objective, to be tested at a 2-sided 0.05 level, when median follow-up was at least 5 yrs. The comparison of E+OFS vs T was a secondary objective. The primary end point was invasive DFS. Secondary end-points included invasive breast cancer-free interval (BCFI), distant recurrence-free interval (DRFI) and overall survival (OS).

Results: As expected, the prior chemotherapy cohort represented a higher risk group (table).

After a median follow-up of 67 months, 5-yr DFS was 86.6% in the T+OFS group and 84.7% in the tamoxifen group (HR=0.83; 95%CI, 0.86-1.04; P=0.10). Multivariable allowance for prognostic factors suggested a greater treatment effect (HR 0.78; 95% CI, 0.62-0.98). Overall survival is not mature with 5-yr OS of 96.7% for T+OFS and 95.1% for tamoxifen (HR 0.74; 95% CI, 0.51-1.09; P=0.13). In the no-chemotherapy cohort, one-third of events were not breast-cancer related and BCFI was > 95% with tamoxifen alone. The cohort who remained premenopausal after chemotherapy had a 4.5% absolute improvement in 5-yr BCFI with T+OFS vs T (table). In the chemotherapy cohort, 5-yr overall survival was 94.5% for T+OFS and 90.9% for T (HR=0.64; 95% CI, 0.42-0.96).
Non-adherence with OFS reached 22% at 4 years. Targeted > grade 3 toxicities were reported for 31.3% of T+OFS group and 23.7% of tamoxifen group. Menopausal symptoms, depression, musculoskeletal complaints, hypertension and diabetes were more frequent with T+OFS. Osteoporosis was reported in 5.8% for T+OFS and 3.5% for T.

**Conclusions:** Adding ovarian suppression to tamoxifen did not show significant benefit in the overall population in SOFT after 67 months median follow-up. However, for the cohort of women who received chemotherapy and who remained premenopausal, the addition of ovarian suppression improved breast cancer outcomes, and further improvement was seen with the use of exemestane plus ovarian suppression.
Title: Patient-reported endocrine symptoms, sexual functioning and quality of life (QoL) in the IBCSG SOFT trial: Adjuvant treatment with tamoxifen (T) alone versus T plus ovarian function suppression (OFS) in premenopausal women with hormone receptor-positive (HR+) early breast cancer (BC)

Karin Ribi1, Weixiu Luo1, Juerg Bernhard1, Prudence A Francis1, Meritxell Bellet1, Harold J Burstein1, Lorenzo Pavesi1, Vani Parmar1, Carlo Tondini1, Marilena Visini1, Roberto Torres1, Per Karlsson1, Simon Spazzapan1, Antoni Avella1, Thomas Ruhstaller1, Fabio Puglisi1, Meredith M Regan1, Alan S Coates1, Richard D Gelber1 and Gini F Fleming1. 'SOFT Investigators and International Breast Cancer Study Group, Bern, Switzerland.

Body: Background: SOFT efficacy results reported at this SABCS show that T+OFS provides improved disease control compared with T for the cohort of patients (pts) who received prior chemotherapy (chemo), but relatively little is known about treatment-related endocrine symptoms, sexual function and QoL in premenopausal women receiving adjuvant T+OFS compared with T.

Methods: From Nov 2003 to Apr 2011, 1,722 premenopausal pts with HR+ BC were enrolled and included in the QoL analysis of the randomized phase III trial SOFT, to receive adjuvant treatment with 5 yrs T or T+OFS. A third group received exemestane+OFS and is not included in this report. SOFT enrolled two cohorts: pts who received no chemo, and those who received prior chemo with confirmed premenopausal estradiol levels within 8 mos of completing chemo. Pts completed a questionnaire consisting of global and symptom-specific indicators at baseline, every 6 mos for the first 24 mos, and annually yrs 3 to 6. Differences in change of QoL from baseline between the two treatments were tested at short-, intermediate-, and long-term (6, 24 and 60 mos post-randomization, respectively) for 13 symptoms and 4 global QoL indicators using mixed models with repeated measures, overall and by chemo stratum.

Results: Changes of global QoL indicators (mood, physical wellbeing) from baseline were small and similar between treatments over the whole observation period, but treatment differences were seen with respect to symptom-specific indicators, especially for patients in the no chemo cohort. Overall, pts on T+OFS were substantially more affected by hot flushes than pts on T alone at short- and intermediate-term (each p<.0001). The change of hot flushes from baseline improved for the T+OFS but not for the T alone group over the period of 60 mos. Pts on T+OFS reported more loss of sexual interest (p<.0001) and sleep problems (p<.0001) at short-term, and more vaginal dryness over the whole treatment period (each p<.01). Pts on T alone reported more vaginal discharge up to 60 mos (each p<.05), but only among those pts who did not receive prior chemo. Symptom-specific treatment differences (hot flushes, sleep problems, vaginal discharge) were less pronounced in pts who had received prior chemo. Although pts receiving no prior chemo had less improvement in coping and greater treatment burden with T+OFS vs. T (p<.05), no such treatment differences were seen for pts in the prior chemo cohort.

Conclusion: Global QoL (mood and physical wellbeing) did not differ between groups. Overall, pts receiving T+OFS experienced worse endocrine symptoms and sexual functioning than those receiving T alone during the first two years of treatment; most differences between treatments were no longer apparent thereafter. Differences between T+OFS and T with respect to impaired symptom-specific QoL, being burdened by treatment, and having delayed adaptation during the first two yrs of treatment were less pronounced for pts who received chemo prior to enrolling in SOFT, the cohort that benefited most from OFS in terms of disease control.
Title: Macrophage-specific deletion of STAT5 disrupts normal mammary gland development and accelerates mammary tumorigenesis

Nicholas J Brady¹, Michael A Farrar¹ and Kathryn L Schwertfeger¹. ¹University of Minnesota, Minneapolis, MN.

Body: Fibroblast growth factor receptor 1 (FGFR1) is amplified in 10% of human breast cancers and the ligands for FGFR1 are overexpressed in 60% of triple negative breast cancers. Previous studies using a mouse model of FGFR1-induced mammary tumorigenesis demonstrated that FGFR1 activation in mammary epithelial cells recruits macrophages to hyperplastic regions where they promote angiogenesis and epithelial cell proliferation. Clinically, patients with increased numbers of tumor-associated macrophages have increased risk of relapse and decreased overall survival. While these previous studies demonstrate a role for macrophages during tumor initiation and progression the specific mechanisms that orchestrate the pro-tumor response are poorly understood. Our work uses numerous in vitro and in vivo models to study the dynamic interactions between mammary epithelial cells and macrophages. In an initial screen, we identified the transcription factor signal transducer and activator of transcription 5 (STAT5) as being rapidly activated in macrophages in response to tumor cell-derived factors and modulating pro-tumor functions of macrophages. To assess the role of STAT5 in macrophages during normal mammary gland development, we created a macrophage-specific conditional knockout mouse line with Cre recombinase expression driven by the Csf1r promoter. Mice carrying a macrophage-specific deletion of STAT5 (Stat5 fl/fl ; Csf1r-Cre +) show increased epithelial cell proliferation and impaired ductal elongation at 6 weeks of age compared to littermate controls (Stat5 fl/fl ; Csf1r-Cre -). Based on these data, we hypothesized that the loss of STAT5 in macrophages would accelerate mammary tumorigenesis. To test this, we crossed the macrophage-specific STAT5 knockout mice with a mouse model of FGFR1-induced mammary tumorigenesis. FGFR1 activation was induced in the mice for 2 or 4 weeks beginning at 6 weeks of age. Consistent with previous reports, activation of FGFR1 in mammary epithelial cells results in increased proliferation and lateral bud formation. Surprisingly, mice with STAT5-deficient macrophages show signs of accelerated tumorigenesis, with increased proliferation and numerous instances of hyperplasia in the first 2 weeks of FGFR1 activation. Future studies will focus on understanding the downstream effects of STAT5 deletion in macrophages and the therapeutic potential of targeting this pathway in vivo. All together, these data demonstrate that STAT5 is a critical factor that allows macrophages to regulate normal mammary gland development. In addition, this work illustrates that the loss of STAT5 in macrophages can cooperate with a common genetic event in mammary epithelial cells during breast cancer initiation.

Title: Principles governing A-to-I RNA editing in breast cancer transcriptome

Debora Fumagalli¹, David Gacquer², Françoise Rothé¹, Anne Lefort², Frederick Libert², David N Brown¹, Naima Kheddoumi¹, Adam Shlien³, Tomasz Konopka², Roberto Salgado¹, Denis Larsimont¹, Kornelia Polyak⁴, Karen Willard-Gallo¹, Christine Desmedt¹, Martine Piccart¹, Marc Abramowicz², Peter J Campbell³, Vincent Detours² and Christos Sotiriou¹. ¹Jules Bordet Institute, Brussels, Belgium; ²Université Libre de Bruxelles (ULB), Brussels, Belgium; ³Wellcome Trust Sanger Institute, Hinxton, United Kingdom; ⁴Dana-Farber Cancer Institute, Boston, MA and ⁵Hospital Erasme, Brussels, Belgium.

Body: Background: Messenger RNA (mRNA) is the target of a series of post-transcriptional modifications that can affect its structure and stability, one of the most relevant being RNA editing. The most common form of RNA editing in humans is of the A-to-I type and is catalyzed by the adenosine deaminase acting on RNA (ADAR) family of enzymes. Currently, little is known about how RNA editing operates in cancer. The main objectives of this study were to investigate and characterize the extent of A-to-I RNA editing in breast cancer (BC) and to define the principles governing the editing process in this as well as other cancers.

Material and Methods: The exome and transcriptome of 58 BC samples representing the four main known subtypes, namely TN, HER2+, luminal A and luminal B, and 10 matched normal samples were sequenced using the Illumina platform. For the same series, gene expression and copy number profiles were obtained using the Affymetrix platform. RNA-DNA single nucleotide differences (RDDs) were called using a pipeline in line with the most updated bioinformatics tools and validated in an independent cohort of 15 BC samples and breast cell lines.

Results: Overall, we detected 16,027 RDDs present in one or more samples, with all possible base changes represented. Among these, 560 RDDs were located in Alu regions and were all of the A-to-I type consistent with the notion that A-to-I editing occurs predominantly in forward-facing Alu forming double stranded RNA duplexes processed by ADAR. We found that the same sites were edited in normal and tumor breast tissues. However, the editing frequency was significantly higher in tumors compared to matched normal breast tissues. Moreover, high editing frequencies were observed in samples in which more editing sites were detectable and/or in which ADAR expression was high. We identified two key factors that independently determine ADAR expression and therefore A-to-I RNA editing in breast and the majority of other human cancers: 1) the type-I interferon response in tumors and 2) gains in ADAR copy number. The mean editing frequency was found to be significantly correlated with the expression of STAT1 and other type I interferon target genes, both in our patient series, in a large pool of BC datasets and a panel of normal and breast cancer cell lines treated with interferon (IFN) α, β, or γ for 1, 2 and 5 days in vitro. Moreover, the association between editing and STAT1 expression or ADAR amplification was validated in 19 additional cancer types obtained from the TCGA dataset.

Conclusions: Our work, which represents the largest survey so far on RNA editing in BC, shows that A-to-I editing is a pervasive and well-controlled phenomenon in cancer that can drive aberrant transcriptome expression in breast and potentially the vast majority of cancers. Moreover, it suggests that the immune response can profoundly impact the transcriptome sequence in tumor cells and thereby influence the internal mechanisms governing their behavior.
Title: Identification of a notch-driven breast cancer stem cell gene signature for anti-notch therapy in an ER+ presurgical window model

Kathy S Albain¹, Andrei Y Zlobin¹, Kyle R Covington², Brian T Gallahger¹, Susan G Hilsenbeck³, Cheryl M Czerlanis¹, Shelly Lo¹, Patricia A Robinson¹, Ellen R Gaynor¹, Constantine Godellas¹, Davide Bova¹, Kathy Czaplicki¹, Barbara Busby¹, Patrick J Stiff¹, Suzanne AW Fuqua², Lucio Miele³ and Clodia Osipo¹. ¹Loyola University Chicago, Cardinal Bernardin Cancer Center, Maywood, IL; ²Baylor College of Medicine, Houston, TX and ³Louisiana State University, New Orleans, LA.

Body: Background: Resistance to endocrine therapy (ET; tamoxifen or aromatase inhibitors, AI) for ER+ breast cancer is a major cause of mortality and new treatment paradigms are needed. Cancer stem cells drive breast cancer growth and are resistant to standard therapy. Notch signaling aids survival of these resistant stem cells and is inhibited by gamma-secretase inhibitors (GSI). We showed combining GSI with ET in mice caused shrinkage of breast cancer tumors. A presurgical window biomarker modulation model was used to confirm this discovery in humans.

Methods: The GSI MK-0752 was added to ET in patients before definitive surgery (ClinTrials.gov NCT00756717). There were 3 biopsies: day 0 (prestudy), day 14 (after ET alone), and day 25 at definitive surgery (after continued ET plus MK-0752, 350 mg orally 3d on, 4d off, 3d on). Biopsies were analyzed for genes increased or decreased by GSI, to confirm that Notch and cancer stem cell pathways were inhibited. Real-time PCR was used to validate expression of genes identified in pathway analyses of microarray datasets generated from the biopsies. Mammosphere-forming assays were performed to confirm that ET+GSI impacts breast cancer stem cells. The qRT-PCR data were evaluated using ANOVA with repeated measures and ANOVA was performed on mammosphere results.

Results: The accrual goal was met and therapy well-tolerated in 20 evaluable women (PSABCS 2011, abs# S1-5). Of 33 genes identified by analysis of expression microarrays, 19 genes (FDR<8%) were impacted significantly by GSI+ ET (3 increased, 16 decreased) compared to initial biopsy and/or ET alone. Genes with increased expression were DAXX, NOXA (both pro-apoptotic) and LNFG (tumor suppressor). Six of 16 genes that decreased (NOTCH1, NOTCH4, HEYL, HES1, HES5, and HEY2) are Notch pathway-associated genes. The GSI decreased expression of 3 genes from cell cycle and proliferative pathways (Ki67, CCND1, CCNA2) and inhibited 2 genes expressed in cancer stem cells (RUNX1 and ALDH1A1). Five genes directly/indirectly regulated by Notch were decreased by GSI (RICTOR, RPTOR, MMP7, ADAM19, and PRH). Estrogen deprivation for 3 days, mimicking short exposure to an AI, increased mammosphere-forming ability of ER+ breast cancer cells more than 2 fold. The GSI MRK-003 blocked this mammosphere formation by 95%-98%.

Conclusions: A 7-day course of the GSI MK-0752 added to ET in the presurgical window had significant biomarker responses: decrease in Notch signaling, cancer stem cell genes, proliferation-associated genes, the mTORC1 and 2 complex genes RICTOR and RPTOR, metalloproteinases that promote metastasis, and PRH; as well as increase in 3 key genes that promote apoptosis and tumor suppression. These results suggest that 1) GSI inhibited the intended Notch pathway, 2) putative breast cancer stems cells can be targeted by this strategy, and 3) the biomarkers identified create a gene signature for anti-Notch therapy in ER+ breast cancer. Validation of efficacy of the GSI+ET therapy combination and this gene signature in a clinical trial is planned.

Title: Predicting pre-surgical neoadjuvant chemotherapy response in breast cancer using diffuse optical spectroscopic imaging (DOSI): Results from the ACRIN 6691 study

Bruce J Tromberg1, Zheng Zhang2, Anais Leproux1, Thomas D O'Sullivan1, Albert E Cerussi1, Philip Carpenter1, Rita Mehta1, Darren Roblyer3, Wei Yang3, Keith D Paulsen4, Brian W Pogue4, Shudong Jiang4, Peter Kaufman4, Arjun G Yodh7, So-Hyun Chung7, Mitchell Schnall7, Brad Snyder2, Nola Hylton8, David A Boas9, Stefan A Carp9, Steven J Isakoff9 and David Mankoff7.

1University of California, Irvine, CA; 2Brown University, Providence, RI; 3MD Anderson Cancer Center, Houston, TX; 4Dartmouth College, Hanover, NH; 5Boston University, Boston, MA; 6MD Anderson Cancer Center; 7University of Pennsylvania, Philadelphia, PA; 8University of California, San Francisco, CA and 9Massachusetts General Hospital.

Body: Background: DOSI is an experimental imaging technique that employs risk-free near-infrared light for quantitative measurements of breast tissue perfusion, metabolism, and composition without exogenous contrast. A multi-center ACRIN 6691 study was designed to evaluate whether changes from baseline to mid-therapy in a DOSI-derived Tissue Optical Index (TOI) could predict pathologic complete response (pCR) in breast cancer neoadjuvant chemotherapy (NAC).

Methods: DOSI instruments were constructed at the University of California, Irvine and delivered to 6 participating sites. Bedside measurements were conducted by scanning a handheld probe over a region of interest (up to ∼10 x 10 cm²) on both breasts. Instruments were standardized and validated using a common set of tissue simulating phantoms and protocols. DOSI-derived near-infrared absorption and scattering spectra (650-1000 nm) were used to calculate the tissue concentration of oxy- and deoxyhemoglobin (ctO₂Hb, ctHHb), water (ctH₂O), %lipid and the tissue optical index (TOI=ctHHb x ctH₂O/%lipid) in each probe location. Baseline to mid-therapy changes in the tumor to normal (T/N) TOI ratio were evaluated from DOSI images as the primary imaging endpoint for predicting clinical outcome (pCR). 60 female breast cancer patients (ages 28-69 years, mean 48.9±11), with locally advanced disease (tumors >2cm) were enrolled across the 6 institutions. DOSI measurements were performed at baseline, during the first week of therapy, at midpoint, and at the completion of NAC. Logistic regression was used to assess the association between pathologic complete response (pCR) and % change in T/N TOI from baseline to mid-therapy. In addition, area under the receiver operating characteristic curve (ROC AUC) and its corresponding 95% confidence interval were calculated.

Results: Of the 34 participants (mean age 48.4 ± 10.7) with complete and evaluable data, 10 (29%) achieved pCR as determined by central pathology review. The % change in TOI ratio ranged from -82% to 321%, with a median of -36%. Using -40% as a threshold, we found that subjects in the group with a 40% or more decrease in T/N TOI were more likely to be pCR (p=0.0586, OR=4.667, 95% CI: 0.945 to 23.038). The % change in TOI ratio from baseline to mid-therapy has an AUC of 0.604 (95% CI: 0.394 to 0.814) to distinguish pCR from non-pCR.

Conclusions: DOSI has been successfully implemented in a multi-center setting and changes in T/N TOI are a promising predictor of NAC clinical outcome (pCR). A larger study population is needed to fully assess the utility of TOI and other DOSI imaging endpoints for guiding therapies and predicting NAC response in individual subjects.

ACRIN receives funding from the NCI through U01 CA079778 and U01 CA080098.
Impact of intrinsic subtype by PAM50 and other gene signatures on pathologic complete response (pCR) rates in triple-negative breast cancer (TNBC) after neoadjuvant chemotherapy (NACT) +/- carboplatin (Cb) or bevacizumab (Bev): CALGB 40603/150709 (Alliance)

Background: Adding either Cb or Bev to standard NACT significantly increases pCR rates in TNBC (Sikov et al, SABCS 2013). Genomic analysis may help us to identify determinants of response within this clinical phenotype.

Methods: Patients (pts) with clinical stage II-III TNBC received weekly paclitaxel x 12 followed by ddAC x 4 +/- Cb and/or Bev. Pre-treatment biopsies were collected in formalin, RNAlater and OCT; residual disease at surgery was biopsied when possible. Illumina mRNA sequencing (RNAseq) was performed. Gene expression values were normalized to a TCGA subset of clinically TNBC samples prior to downstream analysis. pCR was defined as the absence of residual invasive cancer in the breast (ypT0/is).

Results: PAM50 subtype analysis was performed on 367 pre-treatment samples (of 443 pts who started NACT); pCR results were available for 360, comprising the analysis subset. 87% of these displayed a basal-like gene expression pattern, 2% claudin-low, 4% HER2-enriched, <1% luminal A and 7% normal-like. In pts with basal-like tumors, pCRs rose from 47% to 61% with the addition of Cb (p=0.014), an increment which did not differ significantly from the overall study population (adding in the small number of non-basal-like tumors) (interaction p=0.93). In contrast, the addition of Bev increased pCRs in basal-like tumors from 45% to 64% (p=0.0009), while reducing pCRs in non-basal-likes from 60% to 43% (interaction p=0.024); thus, a basal-like gene expression pattern was predictive of benefit from Bev. Expression of a variety of immune signatures (B cell, T cell, IgG) was positively associated with pCR, but not predictive of increased benefit from either Cb or Bev. High expression of the HER2 amplicon signature was uncommon and not prognostic for pCR overall but was associated with reduced benefit from Cb (interaction p = 0.025). High proliferation, high p53 mutation and low IE (estrogen signaling) signatures were prognostic for higher pCR rates and predictive of benefit from Bev (interaction p=0.031, 0.0017, 0.0002, respectively). In basal-like pts with residual disease, surgical samples often (52%) displayed a normal-like PAM50 pattern, though this might be due to ‘contamination’ in low volume residual disease.

Conclusions: Selection criteria led to accrual of a high % of pts with basal-like tumors, limiting our ability to assess prognostic or predictive impact of intrinsic subtype on pCR. Given that limitation, the magnitude of pCR benefit with Cb was consistent across subtypes, while a basal-like pattern was predictive of greater pCR increment with Bev. Ongoing studies will test a large number of other gene signatures and biomarkers, including the Lehmann et al subtypes. Recognition of clinically relevant subpopulations within TNBC may distinguish pts likely to achieve a pCR from those for whom an investigational approach might be considered.
Title: The Connecticut experiment: 4 years of screening women with dense breasts with bilateral ultrasound

Jean M Weigert¹. ¹Hospitals of Central Connecticut, New Britain, CT and ²Mandell and Blau MD's PC, New Britain, CT.

Body: OBJECTIVE: To determine if the addition of screening breast ultrasound in women with mammographically normal but dense breasts has increased breast cancer detection over the 4 years since the legislation was first enacted in 2009.

METHODS: The study utilized a retrospective chart review. Data collected included: (1) total number of screening mammograms; (2) total number of dense breast screening ultrasounds; (3) screening ultrasound Breast Imaging Reporting Data System (BI-RADS) code results; (4) biopsy results; and (5) demographic data on women with malignant biopsies. Data was obtained from included sites from October 2009 through December 2013.

FINDINGS: Data was collected from 2 Radiology practices with a total of 5 sites. In year 1, 30670 mammograms and 2706 screening ultrasounds were performed. In year 2, 32050 mammograms and 3351 ultrasounds; in year 3, 32230 mammograms and 4128 ultrasounds and in year 4, 27937 mammograms and 3331 ultrasounds were performed.

In year 1, 151 ultrasounds were BIRADS 4 or 5 with 11 cancers detected. The PPV was 7.1%; the detection rate was 4/1000 and 22% of eligible women had the study (assuming 40% of women have dense breasts). In year 2, 180 ultrasounds were BIRADS 4 and 5 with 11 cancers detected. The PPV was 6.1% and the cancer detection rate was 3.2/1000 with 26% of eligible women having the study. In year 3, 148 ultrasounds were BIRADS 4 and 5 with 13 cancers detected. The PPV was 8.1% and the cancer detection rate was 3.2/1000 with 32% of eligible women having the study. In year 4, 53 ultrasounds were BIRADS 4 and 5 with 11 cancers. The PPV was 17.2% with the cancer detection rate of 3.3/1000 and 28% of eligible women having the study.

CONCLUSIONS: Based on the data collected from these sites, screening breast ultrasound in women with dense breast parenchyma detects mammographically occult malignancy. Over the 4 years studied, the PPV improved from 7% to 17.2% indicating that the selection of lesions biopsied was more accurate with fewer false positives. The rate of detection in the first year was 4.0/1000 and then remained stable at 3.2/1000 in the three subsequent years. Of concern, the number of eligible women who elect to have the additional test remains low at about 30% which is due to several factors including education and cost.
Title: Accelerated partial breast irradiation using intensity modulated radiotherapy versus whole breast irradiation: 5-year survival results of a phase 3 randomized trial

Lorenzo Livi1, Icro Meattini1, Livia Marrazzo2, Stefania Pallotta2, Gabriele Simontacchi1, Calogero Saieva3, Vieri Scotti1, Carla De Luca Cardillo1, Paolo Bastiani4, Jacopo Nori5, Lorenzo Orzalesi6 and Simonetta Bianchi7. 1Radiotherapy-Oncology Unit, Florence University Hospital, Florence, Italy; 2Medical Physics Unit, Florence University Hospital, Florence, Italy; 3Cancer Research and Prevention Institute, Florence, Italy; 4S. Maria Annunziata Hospital, Florence, Italy; 5Florence University Hospital, Florence, Italy; 6Breast Surgery Unit, Florence University Hospital, Florence, Italy and 7Florence University Hospital, Florence, Italy.

Body: Background. Accelerated partial breast irradiation (APBI) has been introduced as an alternative treatment method for selected patients with early stage breast cancer (BC). Intensity modulated radiotherapy (IMRT) had theoretical advantage of further increase in dose conformity compared to 3D technique, with more normal tissue sparing. We present the results of a randomized equivalence trial comparing local recurrence and survival of APBI using IMRT technique to conventional WBI in early stage BC.

Methods. This study was performed at the University of Florence (Florence, Italy). Women aged more than 40 years affected by early breast cancer, with a maximum tumor diameter of 25 mm, suitable for breast-conserving surgery, were randomly assigned in a 1:1 ratio to receive either external whole-breast irradiation (WBI) or APBI using IMRT technique. Patients in the APBI arm received a total dose of 30 Gy in 5 fractions to the tumor bed. Those in the WBI arm received 50 Gy in 25 fractions, followed by a boost of 10 Gy in 5 fractions. For this equivalence trial the prespecified equivalence margin was local recurrence of 5% in the APBI arm. The primary endpoint was occurrence of ipsilateral breast tumor recurrences (IBTR); overall survival (OS) and treatment toxicity were secondary endpoints. Treatment tolerance was assessed using the acute and late radiation morbidity scoring scheme from Radiation Therapy Oncology Group (RTOG) and the European Organization for Research and Treatment of Cancer (EORTC). Cosmetic outcome was scored on the Harvard Breast Cosmesis scale. This trial is registered with ClinicalTrials.gov, number NCT02104895.

Results. 520 patients were randomized (260 to external WBI and 260 to APBI with IMRT) between 2005 and 2013. At a median follow-up of 5 years (range 0.6-9.0), we recorded 6 IBTR: 3 sited in the quadrant index (true recurrence) and 6 in other quadrants. The mean time to IBRT was 2.9 years (range 1-4). The 5-year IBTR rate was 1.5% (3 cases) in the APBI group (95% CI 0.1-3.0), within the prespecified equivalence threshold of 5%, in comparison to that of WBI group (1.4%; 95% CI 0-2.8). No statistically significant difference emerged between two groups (log rank test p=0.86).

OS at 5 years did not significantly differ between the groups (p=0.057). We identified 8 deaths (5-year event rate: 2.1%; 95% CI 0.9-3.3), 7 in the WBI group and only 1 in the APBI group. The 5-year overall survival was 96.6% for the WBI group and 99.4% for APBI group.

Concerning acute adverse events, APBI group showed a statistically significant better safety considering any grade of skin toxicity (p=0.0001). No grade 3 toxicity was observed for APBI group. Concerning late side effects, only two cases (0.8%) experienced grade 2 toxicity in WBI group (skin fibrosis). In both treatment groups the cosmetic result was rated as excellent/good for more than 90% of patients. Overall, APBI group showed better outcome to WBI group (p=0.045).

Conclusions. To our knowledge this is the first randomized study using IMRT technique for APBI delivery. No statistical difference in terms of IBTR was shown between the two arms. APBI showed a significant better acute and late toxicity profile compared to WBI.
Title: A large prospectively-designed study of the DCIS score: Predicting recurrence risk after local excision for ductal carcinoma in situ patients with and without irradiation

Eileen Rakovitch 1,2,3, Sharon Nofech-Mozes 1,3, Wedad Hanna 1,3, Frederick L Baehner 4,5, Refik Saskin 2, Steven M Butler 4, Alan Tuck 4, Sandip Sengupta 4, Leela Elavathil 6, Prashant A Jani 7,10, Michel Bonin 11, Martin C Chang 1,2,3, Elzbieta Slodkowska 1, Joseph M Anderson 4, Farid Jamshidian 4, Diana B Cherhavaz 4, Steven Shak 4 and Lawrence Paszat 1,2,3.

Body: Background: DCIS patients need better tools to align the aggressiveness of treatment with the aggressiveness of their disease. The DCIS Score (DS) was validated as a predictor of ipsilateral breast recurrence (IBR; DCIS or invasive) in 327 E5194 patients treated by breast-conserving surgery (BCS) without radiation (RT) (Solin, 2013). This Ontario population based DCIS study of 3335 women with DCIS from 1994 to 2003 (Rakovitch, 2013) was conducted to test the DCIS Score as a predictor of recurrence risk in patients treated with BCS alone and in patients treated with BCS+RT.

Methods: REMARK guidelines were followed. Breast pathologists centrally reviewed all H&E slides. The Onco type DX DCIS Score was obtained by standardized quantitative RT-PCR using fixed paraffin embedded tumor. The pre-specified primary objective was to determine the relationship (hazard ratio (HR)/50 units) between the risk of an IBR and the continuous DS (using Cox models) in patients treated with BCS alone with ER+ tumors and clear margins (CM, no ink on tumor).

Results: Tumor blocks were collected for 1569 patients (47% of parent cohort); 718 received BCS without RT (N=571 with CM) and 846 received BCS+RT (N=689 with CM). Median follow-up was 9.4 years. Among 1260 pts with CM, 100 pts treated with BCS alone had an IBR (DCIS, N=44; invasive, N=57); 86 pts treated with BCS+RT had an IBR (DCIS, N=32; invasive, N=55). In the primary analysis, among 571 patients treated by BCS alone with CM the continuous DS was significantly associated with IBR in ER+ patients (HR 2.26; 95%CI 1.41, 3.59; P=0.001) and in all patients (HR 2.15; 95%CI 1.43, 3.22; P=0.001). The DS was also associated with invasive IBR (HR 1.78; 95%CI 1.03, 3.05; P=0.04); similar but non-significant results were noted in the ER+ subgroup (P=0.08). Among 689 pts with CM treated by BCS+RT, the DS was associated with IBR (HR 2.78; 95%CI 1.77, 4.41; P=0.001). There was no interaction between the DS and RT (P=0.40). In multivariable analysis for IBR in CM cases, the HR/50 units for the DCIS Score among patients treated with BCS alone with ER+ tumors and clear margins (CM, no ink on tumor).

Conclusions: DCIS Score quantifies recurrence risk for DCIS patients treated by BCS with or without RT. Integrating the DCIS Score with established risk factors, such as multifocality, age, and tumor size, can help identify DCIS patients treated with BCS alone with low 10 year risk (<10%) of recurrence and those who still have high 10 year risk of recurrence despite RT who may be candidates for more aggressive treatment.

Title: Defective stalled replication fork repair and predisposition to hereditary breast cancer

Shailja Pathania1,2, Sangeeta Bade1, Morwenna Le Guillou3, Karly Burke2, Ying Su1, David T Ting4, Kornelia Polyak1,2, Andrea L Richardson1,5, Jean Feunteun3, Judy E Garber1,2 and David M Livingston1,2. 1Dana-Farber Cancer Institute, Boston, MA; 2Harvard Medical School, Boston, MA; 3Laboratoire Stabilité Génétique et Oncogène, Université Paris-Sud, Gustave-Roussy, Villejuif, France; 4Massachusetts General Hospital, Charlestown, MA and 5Brigham and Women's Hospital, Boston, MA.

Body: BRCA1 is a tumor suppressor gene, and germ line BRCA1 mutations increase the risk of breast cancer. While all cells with BRCA1 mutations exhibit a heterozygous BRCA1mut/+ genotype, cancer develops primarily in females, often at young ages and affects almost exclusively the breast and ovaries. Why BRCA1 shows such tissue specificity, and how a normal cell in a BRCA1 mutation carrier (BRCA1mut/+) gives rise to invasive tumor cells are largely unknown.
To determine whether BRCA1 heterozygosity in cells confers defect in any of the multiple, known, BRCA1 functions is a potentially valuable step in achieving a better understanding of BRCA1 mutation-driven cancer predisposition. Thus, we have analyzed a collection of primary mammary BRCA1mut/+ epithelial cells and skin fibroblasts obtained from BRCA1 mutation carriers for such functions.
We, and others have recently shown that BRCA1 exhibits a new DNA damage repair function – i.e. repair of stalled replication forks (SFR). Stalled forks, when not resolved, lead to mutations, or collapse into double strand breaks (DSBs). Both outcomes result in what is commonly referred to as replication stress (RS), which, when chronic, is a driving force behind cancer development. To determine if SFR is defective in normal/healthy breast cells in BRCA1 mutation carriers, and whether this haploinsufficiency results in the kind of genomic changes that lead to cancer, we have now generated 18 primary fibroblast strains from skin punch biopsies and 10 primary mammary epithelial cell (MECs) strains from prophylactic mastectomies performed on BRCA1 mutation carrying women. This collection includes N=23 different BRCA1 mutations, which, together, span almost the entire BRCA1 gene. BRCA1+/+ control MECs were derived from tissue collected during reduction mammoplasties and control fibroblasts were derived from skin punch biopsies from women with no BRCA1 mutation.
Our current data shows that BRCA1mut/+ strains exhibited multiple, normal BRCA1 functions, including the support of homologous recombination- type double strand break repair (HR-DSBR), cell cycle- associated checkpoint functions, centrosome number control, spindle pole formation, Slug expression and satellite RNA suppression. By contrast, nearly all strains were defective in the repair of stalled replication forks and in the suppression of fork collapse, i.e. replication stress. These defects were rescued by reconstituting BRCA1 heterozygous cells with wild-type BRCA1 cDNA, indicating that they are a product of BRCA1 haploinsufficiency.
In addition, the development of sufficient replication stalling rendered BRCA1mut/+ cells defective in an otherwise intact BRCA1 function, HR-DSBR. No such ‘conditional’ haploinsufficiency was detected in any of the other non-haploinsufficient functions, noted above. Given the importance of replication stress in cancer development and of an HR defect in breast cancer pathogenesis, these defects, when they develop serially, could contribute to the BRCA1 breast cancer development pathway. Finally, given the important role of BRCA2, another hereditary breast cancer gene, in stalled fork stability, a similar analysis for BRCA2mut/+ cells from BRCA2 mutation carriers is currently underway and will also be reported at the meeting.
Body: PARPs (poly-ADP-ribose polymerases) catalyze a protein posttranslational modification termed Poly-ADP-ribosylation (PARylation). PARylation is composed of linear and/or branched repeats of ADP-ribose, whose lengths can reach up to 200 units. The first gene encoding a poly-ADP-ribose polymerase, PARP1, was cloned in 1987. Numerous efforts have now led to the identification of 16 additional PARP enzymes. PARP1 is a nuclear protein that is activated as a result of sensing DNA strand breaks. PARylation levels in a quiescent cell are usually very low. In response to genotoxic stress, PARP1 is recruited to nicked DNA and is rapidly activated. This triggers the synthesis of a large number of PARylated proteins and the initiation of DNA damage repair mechanisms. Cancer cells with defects in double-strand break (DSB) repair, such as BRCA1/2-mutated cells, are reliant on PARP1 activity for genome integrity. These cells undergo unsustainable genetic damage, and eventually, apoptosis upon PARP1 inhibition. Indeed, recent late-stage clinical studies revealed that PARP1 inhibitor treatment significantly prolonged progression-free survival of BRCA-deficient breast cancer patients. Contrary to the fruitful efforts in characterizing the upstream inputs regulating PARP1, its genuine downstream targets, however, remain poorly defined. We recently developed the first mass spectrometry-based approach to a global mapping of the human aspartic acid- and glutamic acid-ADP-ribosylated proteome (Zhang et al., Nature Methods 2013). This method allowed us to identify 1,048 in vivo PARylation sites on 340 proteins. These modified proteins are involved in a wide array of nuclear functions including DNA damage repair, transcription regulation, epigenetic modulation, and mRNA processing. Using a quantitative mass spectrometry experiment, we also identified hundreds of novel PARP1 downstream effectors.

The central hypothesis of our current study is that ADP-ribosylation levels of PARP1 substrates can reflect the activity of PARP1 in a cell. We predict that a signature composed of multiple PARylated proteins can then be used to identify cells that are "addicted" to PARP1 activity for genome integrity. To this end, we performed a large scale profiling of the Asp- and Glu-ADP-ribosylated proteome of a benign breast epithelial cell line (MCF10A), and compared it to that of a panel of eight breast carcinoma cell lines, including the ER+ (MCF7, T47D and ZR-75-1), HER2+ (SKBR3), and triple negative (MDA-MB-231, MDA-MB-468, SUM159 and HCC1937) subtypes. Among these lines, MDA-MB-468 (PTEN null), SKBR3 (HER2+) and HCC1937 (BRCA1 null) are known to be sensitive to PARP inhibitors. We correlated the pattern of protein ADP-ribosylation to their IC50, and found events of predictive value. In addition, we also observed that the differential PARylation pattern among these cells can be divided into a "public" (proteins that are commonly modified across all cell lines) class, and a "private" one (proteins that specifically modified in certain cell lines). We envision that this dataset will also serve as a valuable resource for the PARP1/DNA damage research community to investigate cell line-specific Asp- and Glu-ADP-ribosylation events.
Title: A randomized, open-label, multicenter, phase 3 study of epoetin alfa (EPO) plus standard supportive care versus standard supportive care in anemic patients with metastatic breast cancer (MBC) receiving standard chemotherapy

Body: Background: Several investigational studies including MBC reported that erythropoiesis-stimulating agent (ESA) treatment beyond correction of anemia decreased survival and locoregional tumor control, and/or increased adverse effects, especially thrombotic vascular events (TVEs). These studies were reviewed at 3 FDA Oncologic Drugs Advisory Committee Meetings (2004, 2007, and 2008). Other studies and well-conducted meta-analyses did not suggest adverse effects on tumor outcomes when ESAs are used according to the prescribing information in subjects receiving chemotherapy, however, no study rigorously evaluated tumor outcomes.

This Phase 3 study is the largest MBC trial in subjects receiving EPO for chemotherapy induced anemia specifically designed and conducted to assess progression-free survival (PFS) as the primary endpoint. Conducted as a post-marketing requirement, the study has been regularly and intensively monitored by an Independent Data Monitoring Committee (IDMC) of internationally recognized experts in the fields of MBC treatment, clinical research, and statistics.

Methods: EPO-ANE-3010 (ClinicalTrials.gov #NCT00338286) is a multinational (19 countries and 223 participating sites) study with 2,098 subjects who are anemic and receiving first- or second-line standard chemotherapy for MBC. Key inclusion criteria: histologically confirmed MBC, stage IV disease and at least 1 measurable metastatic lesion according to Response Evaluation Criteria in Solid Tumors (RECIST); hemoglobin (Hb) ≤11 g/dL, Eastern Cooperative Oncology Group performance score 0 or 1. Key exclusion criteria: metastasis to bone only, receiving anticoagulants or endocrine therapy. Subjects were randomly assigned (1:1) to receive either standard supportive care for treatment of anemia (SOC) plus 40,000 IU EPO given subcutaneously weekly up to 4 weeks after the last dose of cytotoxic chemotherapy, or to SOC alone. Randomization was stratified by line of chemotherapy and HER2/NEU status. EPO dose was held for Hb >12 g/dL. Disease was assessed every 8 weeks for the first year, and then every 12 weeks until disease progression (PD) or death. Tumor response was determined according to modified RECIST 1.0 criteria by Investigators and Blinded Central Review. Overall survival (OS) follow up continued after PD. The primary endpoint is PFS. Secondary endpoints include OS, time to tumor progression, and overall response rate and safety assessments (including incidence and severity of TVEs). For this non-inferiority study, a sample size of 1,650 disease progression or death events was determined to provide over 80% power to rule out a 15% hazard rate increase (i.e., hazard ratio of 1.15, epoetin alfa vs. control) in PFS with a 1-sided Type I error rate 0.025. The study is fully accrued with 2014 projected key dates: clinical cut-off at 1650 PFS events, July; database lock, September; IDMC agreement on presentation of final results, mid-November. Both primary and secondary endpoints will be fully reported.
Title: Final survival analysis from the randomized Women's Intervention Nutrition Study (WINS) evaluating dietary intervention as adjuvant breast cancer therapy

Rowan T Chlebowski\textsuperscript{1} and George L Blackburn\textsuperscript{2}. \textsuperscript{1}Los Angeles BioMedical Research Institute at the Harbor-UCLA Medical Center, Torrance, CA; \textsuperscript{2}Beth Israel Deaconess Hospital, Boston, MA and \textsuperscript{3}on behalf of the Women's Intervention Nutrition Study Investigators, Torrance, CA.

Body: Between 1994 and 2001, 2,437 women between 48-79 years of age with early-stage breast cancer (73% node negative, 79% estrogen receptor positive, 70% = or < 2 cm) receiving standard cancer management (endocrine therapy +/- chemotherapy if hormone receptor positive or chemotherapy if hormone receptor negative plus radiation therapy if clinically indicated) were randomized, within 6 months of diagnosis, to a dietary intervention or control group from 39 US centers participating in the Women's Intervention Nutrition Study (WINS). The dietary intervention, targeting fat intake reduction while maintaining nutritional adequacy, was initiated during 8 biweekly individual counseling sessions by centrally trained registered dieticians implementing a previously developed low-fat eating plan with subsequent every 3 month dietitian contacts. During 5 years (median) intervention, fat intake was significantly reduced (from 29.2% to 20.3% of calories, P< 0.0001) as was body weight (-2.7 kg, P=0.005) in the dietary intervention group but not in the control group. Relapse-free survival, the primary study endpoint, was favorably impacted in the dietary intervention compared to the control group (9.8% vs 12.4% with events, respectively, HR 0.78 95% CI 0.60-0.98, P = 0.03 from adjusted Cox model) (J Natl Cancer Inst 2006:98;1767). Exploratory analyses suggested a greater dietary effect on women with hormone receptor negative cancers. When intervention ended after 5 years median follow-up with a total of 171 deaths, there were somewhat fewer deaths in the intervention group (6.6% vs 7.3%, HR 0.89 95% CI 0.65-1.21). In the last WINS update, based on national death registry information after 8.1 years median follow-up with a total of 251 deaths, while there were fewer deaths in the intervention compared to the control group (9.1% vs 11.1%), the difference was again not statistically significant (HR 0.78 95% CI 0.59-1.03) (J Clin Oncol 2008:26;522). With this as background, the primary study objective is to determine, with updated survival information after now 15 years median follow-up with a total of 430 deaths, whether a lifestyle intervention targeting fat intake reduction associated with significant weight loss will improve overall survival in early stage breast cancer patients receiving standard breast cancer management. Information on survival is being obtained regarding the status of the 2,081 WINS study participants last known to be alive using the National Death Registry identified through DOBsearch.com. It is anticipated that there will now be a total of approximately 430 deaths in the trial. The new information will be incorporated in updated survival analyses, using time-to-event methods based on intention-to-treat principles, for the overall population and for subgroups of interest. Results will be presented as a late breaking abstract.
Title: Phase 3, randomized, double-blind, placebo-controlled multicenter trial of daily everolimus plus weekly trastuzumab and paclitaxel as first-line therapy in women with HER2+ advanced breast cancer: BOLERO-1

Body: Background: Mammalian target of rapamycin (mTOR) is central to multiple signaling pathways regulating cell growth and proliferation. In early studies, an mTOR inhibitor everolimus (EVE) showed antitumor activity in breast cancer and synergy with both trastuzumab (TRAS) and paclitaxel (PAC). The BOLERO-1 study evaluated the addition of EVE to TRAS+PAC as first-line therapy for HER2+ advanced breast cancer (ABC).

Methods: In this phase 3 randomized trial, women with HER2+ ABC without prior TRAS or chemotherapy for advanced disease were randomized 2:1 to receive either EVE (10 mg/d) or placebo (PBO) and weekly PAC plus TRAS. The two primary objectives were to compare the investigator assessed progression-free survival (PFS) between EVE+TRAS+PAC and PBO+TRAS+PAC in the full population and the Hormone Receptor− negative (HR−) subpopulation. Secondary endpoints included overall survival (OS), response rate, and safety.

Results: 719 patients were randomized to receive EVE (n=480) or PBO (n=239). Final PFS analysis was performed after 425 events in the full population. Baseline characteristics/prior therapies were balanced between two treatment arms; median age was 53 years, 70.5% had visceral metastases, 43.3% were HR−; prior therapy included TRAS (10.8%) and taxane (24.9%); baseline characteristics for the HR− subpopulation were generally balanced between two treatment arms and similar to the overall population. Median study follow-up at the time of analysis was 41.3 mo. The study did not meet its primary objective in the full population; median PFS was 15 mo (95%CI: 14.6-17.9) in the EVE arm vs. 14.5 mo (95%CI: 12.3-17.1) in the PBO arm (HR=0.89 [95%CI: 0.73-1.08]; p=0.1166). In the HR− subpopulation (n=311), a clinically relevant 7.2 mo benefit in median PFS was observed in the EVE arm (20.3 mo [95%CI: 15.0-24.1]) vs. PBO arm (13.1 mo [95%CI: 10.1-16.6]; HR=0.66 [95%CI: 0.48-0.91]; p=0.0049), which just fell short of crossing the protocol pre-specified level of statistical significance (p=0.0044). Additional sensitivity analysis of PFS without censoring patients at the start of new antineoplastic therapy yielded hazard ratio consistent with the primary analysis (p=0.0043). PFS based on central assessment corroborated investigator assessed PFS in both the full population and HR− subpopulation. OS data is immature. Safety profile of EVE was consistent with previous observations in ABC; no new signals were identified. Most common adverse events (AEs) in the EVE arm vs. PBO arm were stomatitis (66.5% vs. 32.4%), diarrhea (56.6% vs. 46.6%), and alopecia (46.8% vs. 52.5%); suspected drug-related serious AEs were reported for 21.8% vs. 7.6%, and on-treatment AE related deaths were reported for 3.6% vs. 0.0% of patients, respectively.

Conclusions: First-line therapy with EVE+TRAS+PAC did not show PFS benefit in patients with HER2+ ABC; the HR− subpopulation derived a clinically robust benefit of 7.2 mo in median PFS suggesting that EVE may have a role in this patient subpopulation. EVE+TRAS+PAC toxicity was generally manageable; no new safety signals were identified. (Funded by Novartis; ClinicalTrials.gov number, NCT00876395.)

Title: TBCRC023: A randomized multicenter phase II neoadjuvant trial of lapatinib plus trastuzumab, with endocrine therapy and without chemotherapy, for 12 vs. 24 weeks in patients with HER2 overexpressing breast cancer

Mothaffar F Rimawi\textsuperscript{1}, Polly A Niravath\textsuperscript{1}, Tao Wang\textsuperscript{2}, Brent Rexer\textsuperscript{2}, Andres Forero\textsuperscript{3}, Antonio C Wolff\textsuperscript{4}, Rita Nanda\textsuperscript{5}, Anna M Storniolo\textsuperscript{6}, Ian Krop\textsuperscript{7}, Matthew P Goetz\textsuperscript{6}, Julie R Nangia\textsuperscript{1}, Sao Jiralerspong\textsuperscript{1}, Anne C Pavlick\textsuperscript{1}, Carolina Gutierrez\textsuperscript{1}, Rachel Schiff\textsuperscript{1}, Susan G Hilsenbeck\textsuperscript{1} and C Kent Osborne\textsuperscript{1}. \textsuperscript{1}Baylor College of Medicine, Houston, TX; \textsuperscript{2}Vanderbilt University, Nashville, TN; \textsuperscript{3}University of Alabama, Birmingham, AL; \textsuperscript{4}Johns Hopkins University, Baltimore, MD; \textsuperscript{5}University of Chicago, Chicago, IL; \textsuperscript{6}Indiana University, Indianapolis, IN; \textsuperscript{7}Dana-Farber Cancer Institute, Boston, MA and \textsuperscript{8}Mayo Clinic, Rochester, MN.

Body: Background: We have previously shown in animal models that combination anti-HER2 therapy leads to complete tumor regression of HER2+ breast cancer (BC). We translated these findings in a neoadjuvant trial of 12 weeks (wks) of L+T (TBCRC006) that demonstrated a meaningful pathologic complete response (pCR) and near pCR (in ER+ tumors) in patients with locally advanced HER2+ BC. In the present trial, we sought to determine whether longer treatment would lead to a higher rate of pCR without the use of chemotherapy by converting near pCR to pCR especially in the ER+ subset.

Methods: TBCRC023 (NCT00999804) is a randomized phase II trial combining a Simon Phase 2 design in the experimental arm with a pick-the-winner design, not powered for direct comparison. Women with HER2+ BC measuring 2 cm or larger were eligible and were randomized in a 1:2 ratio to 12 vs. 24 wks of L+T. Letrozole (along with ovarian suppression if premenopausal) was also administered in patients whose tumors were also ER+. Serial tumor biopsies were obtained at baseline, wk 1, wk 12, and at the time of surgery. All evaluable patients were assessed for pCR, defined as no residual invasive carcinoma in the breast. Patients did not undergo surgery, withdrew consent, or received additional neoadjuvant therapy were counted as non-responders.

Results: Ninety-seven patients were enrolled (33 in 12-wk arm and 64 in 24-wk arm), of whom 95 were evaluable. Seventy-seven percent of patients were white and 18% were black. Twenty percent were of Hispanic ethnicity. Median age was 51 and 55% were postmenopausal. Median tumor size was 5 cm and 65% were ER+. Study treatment was well tolerated with grade 1-2 diarrhea (24% in 12-wk arm, 31% in 24-wk arm) and grade 1-2 acneform rash (12% in 12-wk arm, 19% in 24-wk arm) being the most common toxicities. Grade 3 toxicities were uncommon and were mostly in the 24-wk arm (elevated liver function test: 9%, diarrhea 2%, mucositis 2%), while the 12-wk arm had one grade 3 anemia and the study’s only serious adverse event (acute kidney injury). There were no grade 4 toxicities.

The experimental arm completed stage 2 accrual and pCR rate was numerically superior to control, entirely due to better results in ER+ (Table 1), but lower than the expected pCR rate of 36% needed in the planned analysis to conclude in favor of enhanced efficacy with extended therapy. pCR rates were also lower in the control arm than in the previous study.

Conclusions: Treatment with L+T (with endocrine therapy in ER+ tumors) for 24 weeks leads to doubling of the pCR rate in women with HER2+ breast cancer without using cytotoxic chemotherapy. This approach is effective and well tolerated and warrants study as part of a de-escalation strategy that may spare some patients the cost and toxicity of chemotherapy. Tissue obtained on this trial will provide a valuable resource to validate correlative findings from our prior studies and discover new biomarkers to help guide proper patient selection for treatment.
Purpose: Fulvestrant (F) is a selective estrogen receptor downregulator (SERD) with activity in aromatase-inhibitor (AI) resistant estrogen receptor (ER)-positive metastatic breast cancer (MBC). In preclinical studies, the proteasome inhibitor bortezomib (B) enhances the antineoplastic effects of F, in part by promoting accumulation of large ER-aggregates that lead to cell death (Ishii et al. Clin Cancer Res 2011 17:2292). The objective of this study was to determine if the combination of F+B was more efficacious than F alone in MBC after AI progression.

Patients and Methods: Postmenopausal women with ER-positive MBC who had progressive disease after prior AI therapy were eligible. They were randomized to F alone (500 mg IM days -15, 1, 15 in cycle 1, and day 1 of each subsequent cycle) or in combination with B (1.6 mg/m² IV on days 1, 8, 15). The primary endpoint was progression free survival (PFS), measured from cycle 1, day 1 of starting F. A sample size of 118 was pre-specified in order to provide sufficient power to detect an improvement in median PFS from 5.4 to 9.0 months, and compare PFS rates after 6 and 12 months (1-sided alpha=0.10, beta=0.10). Patients with progression on F could cross over to the F+B combination.

Results: Of 118 patients enrolled, 59 received F alone (arm A), 57 received F+B (arm B), and 2 assigned to arm B never initiated protocol therapy. There were no significant differences in patient characteristics between arms with regard to median age (57 vs. 59 years), ECOG performance status (0 and 1, 64% and 36%, respectively), prior chemotherapy for metastasis (25%), or liver metastases (37%), although patients in arm A had longer median interval between diagnosis and metastasis (49 vs. 28 months) and were more likely to present with metastasis (32% vs. 26%). Patients in arm B had more adverse events (all grades), including nausea (63% vs. 29%), diarrhea (47% vs. 8%), sensory neuropathy (46% vs. 29%), and limb edema (37% vs. 19%), although grade 3-4 events were uncommon, and only 11% discontinued B due to toxicity. At 12 months, the PFS proportion in Arm A and Arm B was 13.6% vs. 28.1%, respectively (P=0.03, 1-sided chi-square test) (95% CI for difference [14.5%] = -0.06%, 29.1%).

Although median PFS was similar in the two arms (2.69 vs. 2.73 months, respectively), the hazard ratio for Arm B vs. Arm A (referred) was 0.73 (95% CI = 0.49, 1.09, P=0.06, 1-sided log rank test). Both results were significant at the pre-specified 1-sided 0.10 alpha level. Of 27 patients on arm A who crossed over to F+B at progression, 4 (15%) were progression-free for at least 24 weeks and had periods of disease control that were longer than when treated with F alone.

Conclusion: Adding bortezomib to fulvestrant in AI-resistant ER-positive MBC enhances its effectiveness by delaying acquired fulvestrant resistance. These results support additional evaluation of proteasome inhibitors in combination with SERDs.

Acknowledgement: Supported by contract N01-CM-62204 to the New York Cancer Consortium (P.I. J. Sparano) and grant P30 CA013330 (P.I. D. Goldman) from the National Institutes of Health, and by a grant from Millennium, Inc.
**Title:** Fulvestrant 500 mg versus anastrozole as first-line treatment for advanced breast cancer: overall survival from the phase II ‘first’ study

John FR Robertson¹, Antonio Llombart-Cussac², David Feltl³, John Dewar⁴, Marek Jasiówka⁵, Nicola Hewson⁶, Yuri Rukazenkov⁶ and Matthew J Ellis⁷. ¹University of Nottingham, Derby, Nottingham, United Kingdom; ²Hospital Arnau de Vilanova, Lérida, Spain; ³FNsP Ostrava, Radioterapeutická Klinika, Ostrava-Poruba, Czech Republic; ⁴Ninewells Hospital and Medical School, Dundee, United Kingdom; ⁵Centrum Onkologii, Instytut im Marii Sklodowskiej-Curie, Kraków, Poland; ⁶AstraZeneca Pharmaceuticals, Macclesfield, United Kingdom and ⁷Washington University School of Medicine, St Louis, MO.

**Body:**

**Background:** Fulvestrant 500 mg showed a clinically significant improvement in median overall survival (OS) vs fulvestrant 250 mg (26.4 vs 22.3 months, respectively; hazard ratio [HR] 0.81; 95% confidence interval (CI) 0.69, 0.96; nominal p=0.02) in the Phase III CONFIRM study, for patients (pts) with hormone receptor positive (HR+) disease following failure on prior endocrine therapy. Further evidence for OS effects of fulvestrant 500 mg was sought in the Fulvestrant fIRst-line Study comparing endocrine Treatments (FIRST), which compared fulvestrant 500 mg with anastrozole as first-line treatment for postmenopausal pts with HR+ locally advanced (LA) or metastatic breast cancer (MBC). In the primary analysis, fulvestrant 500 mg was as effective as anastrozole for clinical benefit rate (primary endpoint) and significantly better for time to progression (TTP; secondary endpoint). In a follow-up analysis, median TTP was 23.4 months for fulvestrant 500 mg vs 13.1 months for anastrozole (HR 0.66; 95% CI 0.47, 0.92; p=0.01). Here we report the only scheduled FIRST OS analysis.

**Methods:** FIRST, a Phase II, randomized, open-label study (NCT00274469), compared fulvestrant 500 mg (im on Days 0, 14 and 28, and every 28 days thereafter) with anastrozole (1 mg/day po). Pts had not received prior endocrine therapy for advanced disease. OS (time from randomization to death) was compared by unadjusted log-rank test after approximately 65% of deaths. Effect of treatment on OS was examined across subgroups (including age, hormone receptor status and visceral disease). Pts alive or not known to have died were right-censored at last known date alive, including 20 pts in centers invited but who did not join the OS follow-up phase. Serious adverse events (SAEs) were recorded.

**Results:** 205 pts (median age 67.0 years) were randomized from 62 centers in 9 countries (fulvestrant 500 mg: n=102; anastrozole: n=103). The first pt enrolled on Feb 6, 2006. As of July 2014, 33/205 pts (16.1%) were known to be alive across both treatment groups and 137/205 (66.8%) pts had died. Median OS was significantly greater for fulvestrant 500 mg (54.1 months) vs anastrozole (48.4 months; HR 0.70; 95% CI 0.50, 0.98; p=0.041). OS analyses in pre-specified subgroups demonstrated a consistent treatment effect for fulvestrant 500 mg vs anastrozole (global interaction test p=0.755). The frequency of SAEs was similar between fulvestrant 500 mg (23.8%) and anastrozole (21.4%).

**Conclusions:** HR+ pts receiving first-line fulvestrant 500 mg lived significantly longer than pts on anastrozole (median OS difference of 5.7 months). A consistent OS treatment effect was observed across predefined subgroups. FIRST is therefore the second randomized trial to show an OS advantage for fulvestrant 500 mg over another endocrine therapy. No new safety signals were identified with longer-term treatment. Improved OS data provide further support for superior efficacy of fulvestrant 500 mg over anastrozole as first-line endocrine therapy for postmenopausal women with HR+ LA or MBC. If confirmation of superiority for fulvestrant 500 mg is seen in the Phase III FALCON study (NCT01602380), fulvestrant 500 mg should be considered for approval as a first-line agent in this setting.
Body: Intro: Male BC is a rare disease (<1% male tumors); knowledge is limited and management extrapolated from female BC. An international consortium, coordinated by EORTC and TBCRC, was created to better characterize and manage this disease, with 3 parts: 1) retrospective joint analysis 2) prospective registry 3) clinical trial(s). We report 1st results of part 1. Methods: Joint analysis of male BC pts with available FU & FFPE samples, treated in 1990-2010, in 23 centers from 9 countries. Clinical data, long term outcomes, local pathology were centrally analyzed at EORTC. FFPE samples were analyzed at 3 central labs (UK, NL, US) for histology, grade, ER, PR, AR, HER-2, Ki67. Cut-off for positivity: Allred score ≥3 for ER, AR, PR; 20% for Ki67; Average Grade: 6.80; 35% use number of non-missing values as denominator. Results: 1822 pts enrolled; 349 (19%) were excluded (no valid central lab assessment); of 1473 eligible pts (1384 from EU, 89 from US) 63% diagnosed in 2001-2010. Median age at diagnosis (Dx) was 68.5 ys. Of pts with known M status at Dx, 56 (5.1%) were M1; of 1046 M0 cases, 60% were N0 and 51% had T1 tumors at Dx; 4% of pts had BCS and 18% had SLNB; half received adjuvant RT. (Neo)adjuvant CT was used in 30% of M0 pts, most (44%) anthracycline-only; 77% of M0 pts received adjuvant ET, most tamoxifen (88.4%). Central pathology: 697 cases with central histology & grade (full series ongoing): 87% ductal, 53% grade 2. In 1473 pts, at least 1 biomarker centrally assessed; 92% ER highly+ (Allred 7-8), PR had wider variation (35% highly+); 87% AR highly+; 25% Ki67 high; 5% HER2pos. Using IHC surrogates: 58% Luminal A-like, 35% LuminalB-like/HER2neg, 6% LuminalB-like/HER2pos; 0.1% HER2pos/non-Luminal; 1% TNBC (16% not classified). Outcome: For 1046 M0 pts, median FU was 5.7 yrs (0-19.2); 63% alive at analysis; in 88% cause of death was reported, mainly 33% non-cancer and 28% progression(PD)/toxicity. Significant OS improvement over time is seen. 75% (42/56) M1 pts died, mainly due PD. In M0 pts, median OS (yrs) was significantly correlated with ER+ p=0.001 [Allred 0-2: 3.9 (0.1, 6.0); 3-6: 7.1 (4.7, 11.7); 7-8: 8.8 (8.3, 10.0)] & with PR+ p=0.022 [Allred 0-2: 7.3 (6.1, 10.3), 3-6: 8.0 (7.0, 9.3), 7-8: 9.5 (8.4, 12.8)]; less correlation for AR; no major differences for HER2 or Ki67. Median OS & grade
(394 cases; full series ongoing): Grade1: 12.8 yrs (6.1-15.6); Grade2: 7.9 (6.5-10.7); Grade3: 9.3 (4.9-21.1). Median OS for IHC surrogates: 8.7 (7.8-9.7) for Luminal A; 8.3 (6.9-9.4) for Luminal B/HER-2neg; 9.3 years (5.9-21.1) for Luminal B/HER-2+. Similar results were seen for RFS. ER/PR/AR using histoscores will be presented. Conclusions: a) 56% pts had T1 tumors at Dx but only 4% had BCS; b) ER was highly + in >90% but adjuvant ET given in only 77% pts; c) Male BC is usually ER+, PR+ & AR+ and of Luminal A-like subtype (5% HER2pos & 1% TNBC); d) Significant improvement in OS over time; e) ER and PR (Allred) are prognostic (high expression/better prognosis), less for AR, not for Ki67 nor IHC surrogates; f) In-depth characterization of samples is ongoing. The genomic landscape of male breast cancers

Salvatore Piscuoglio, Melissa Murray, Charlotte KY Ng, Elena Guerini Rocco, Luciano G Martelotto, Francois-Clement Bidard, Carey A Eberle, Nicola Fusco, Rita A Sakr, Leticia De Mattos-Arruda, Raymond Lim, Timour Baslan, James Hicks, Tari A King, Edi Brogi, Larry Norton, Britta Weigelt, Clifford A Hudis and Jorge S Reis-Filho. 1Memorial Sloan Kettering Cancer Center, New York, NY; 2School of Pathology, University of Milan, Milan, Italy; 3Institut Curie, Paris, France; 4Memorial Sloan Kettering Cancer Center, New York, NY; 5Cold Spring Harbor Laboratory, Cold Spring Harbor, NY and 6Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Background: Male breast cancer (MaBC) accounts for <1% of all breast cancers and its genomic landscape has yet to be characterized. The majority of MaBCs are ER-positive invasive ductal carcinomas of no special type and, unlike female breast cancers (FBC), rarely display HER2 gene amplification or a triple-negative phenotype. Given the relative rarity of MaBCs, treatment decisions for MaBC patients are often extrapolated from trials carried out with FBC patients. Here we employed targeted capture massively parallel sequencing to define the repertoire of somatic mutations and gene copy number alterations (CNAs) in MaBCs.

Methods: Subtyping of the 64 MaBCs included in this study was performed by means of immunohistochemistry using the definitions described in the latest St. Gallen’s consensus report. DNA extracted from microdissected tumor and adjacent normal tissue were subjected to massively parallel targeting sequencing of all exons of 273 genes most frequently mutated in FBCs or directly related to DNA repair. Somatic mutations were defined using a combination of MuTect, SomaticSniper, MutationSeq and Haplotype Caller. Selected mutations were validated with Sequenom MassARRAY. CNAs were identified using Varscan2 and GISTIC2.0. Pathway and network analysis of mutations/CNAs was performed using Ingenuity Pathway Analysis and HOTNET. The genomic landscape of MaBCs was compared with that of FBCs of the same subtype analyzed as part of The Cancer Genome Atlas project.

Results: All MaBCs were ER-positive and HER2-negative. Using the St. Gallen’s criteria, 37.5% and 62.5% were classified as luminal A-like or luminal B-like, respectively. The genes most frequently mutated in MaBCs were PIK3CA, GATA3, FLG and PLEC, with PIK3CA being the only significantly mutated gene as defined by MutSigCV (q=0.003). CNA analysis revealed recurrent gains of 1q and 8q and loss of 16q. GISTIC2.0 identified significantly recurrent high-level amplifications in 1q25.3, 8p11 (FGFR1, ZNF703), 8q24.3 (DEPTOR), 17q23 (PPM1D) and 15q26 (IGF1R) and deletions in 11q22 (ATM) and 21q22.12 (RUNX1). HOTNET analysis of the genes mutated and/or targeted by gene amplifications in MaBCs revealed significantly altered subnetworks involving genes related to DNA repair, PI3K and FGF signaling pathways. The most frequently mutated genes in luminal A-like MaBCs were PIK3CA and MLL3, while those of luminal B-like MaBCs were PIK3CA and GATA3. MLL3 and GATA3 mutations were only found in luminal A-like MaBCs (p=0.039) and luminal B-like MaBCs (p=0.048), respectively. Although the mutational landscapes of MaBCs and luminal FBCs were qualitatively similar, PIK3CA and TP53 were less frequently mutated in MaBCs (p<0.001), whereas genes found to be recurrently mutated in FBCs, such as MAP2K4 and NCOR1, were not mutated in MaBCs.

Conclusions: MaBCs are preferentially of luminal subtype and are characterized by recurrent mutations in PIK3CA, GATA3, FLG and PLEC. Genetic alterations in MaBCs often target DNA repair and FGF signaling pathways. The known drivers of luminal FBCs appear to be less frequently altered in MaBCs. Given these important differences between MaBCs and FBCs, caution should be exercised in the extrapolation of biologic and clinical implications from studies in FBCs to the management of MaBCs.
**Title:** LORELEI: A Phase II randomized, double-blind study of neoadjuvant letrozole plus taselisib (GDC-0032) versus letrozole plus placebo in postmenopausal women with ER-positive/HER2-negative, early stage breast cancer

Cristina Saurà, Evandro de Azambuja, Peter Dubsky, Mafalda Oliveira, Kamal S Saini, Christian Fes, Ray S Lin, Timothy R Wilson, Jill Fredickson, Hema Parmar, Jerry Y Hsu, Martine Picard, Michael Gnant and Jose Baselga.

1 Vall d’Hebron University Hospital, Barcelona, Spain; 2 Jules Bordet Institute, Brussel, Belgium; 3 Medical University of Vienna, Vienna, Austria; 4 Breast International Group, Brussel, Belgium; 5 Austrian Breast and Colorectal Cancer Study Group, Vienna, Austria; 6 Genentech, San Francisco, CA and 7 Memorial Sloan Kettering Cancer Center, New York, NY.

**Body:**

Background: Taselisib (GDC-0032) is an orally bioavailable, potent, and selective inhibitor of Class I PI3-kinase (PI3K) alpha, gamma, and delta isoforms, with 30-fold less inhibition of the PI3K beta isoform relative to the PI3K alpha isoform. Preclinical data show that taselisib has enhanced activity against PIK3CA mutant cancer cell lines. Clinical data have also demonstrated confirmed partial responses in patients with PIK3CA mutant breast cancer treated with single-agent taselisib. Preclinical and clinical data also show enhanced antitumor activity when taselisib is combined with either letrozole or fulvestrant.

Study design: LORELEI is a phase II, two-arm, randomized, double-blind, multicenter, neoadjuvant study of letrozole and taselisib versus letrozole and placebo in postmenopausal women with newly diagnosed ER+/HER2-, untreated, stage I-III operable breast cancer. Other relevant eligibility criteria include tumor size ≥ 2 cm, unilateral disease, ECOG PS ≤ 1, and available and evaluable tumor tissue for central review of PIK3CA mutation analysis. Patients will be randomized (1:1) to receive continuous daily letrozole (2.5 mg) with either placebo or taselisib (4mg on a 5 days on/ 2 days off schedule) for 16 weeks. Study treatment is followed by surgery. Adjuvant treatment will be given as per physician’s discretion. Stratification at randomization is based on tumor size and nodal status.

Endpoints: The co-primary endpoints are overall objective response rate (ORR) by centrally assessed breast magnetic resonance imaging (MRI) via modified RECIST criteria and pathologic complete response (pCR) rate in breast and axilla at time of surgery in all enrolled patients and PIK3CA mutant (MT) patients. Secondary endpoints include ORR by centrally assessed MRI and pCR rate in PIK3CA wild-type (WT) patients. Other secondary endpoints performed in all enrolled patients and separately as per PIK3CA mutation status include: assessment of ORR using breast ultrasound, clinical breast exam (i.e. palpation) and mammography; changes in Ki67 levels from baseline to week 3, baseline to surgery and week 3 to surgery; centrally assessed preoperative endocrine prognostic index (PEPI) score; changes in enhancing tumor volume from baseline to surgery as measured by breast MRI via central assessment. Exploratory analyses include expression of biomarkers predictive of response to letrozole plus taselisib from tumor tissue or blood.

Statistical methods:

The sample size was calculated to detect an absolute percentage increase of 24% in ORR via MRI (40% in the letrozole-placebo arm vs. 64% in the letrozole-taselisib arm in the PIK3CA MT cohort) with 80% power at 16% two-sided significance level. The sample size will also detect an absolute percentage increase of 18% in pCR rate (1% in the letrozole-placebo arm vs 19% in the letrozole-taselisib arm in the PIK3CA MT cohort) with 80% power at 4% two-sided significance level.

Target accrual: Approximately 330 pts at 110 global sites across Europe, North and South America, and Asia-Pacific.

Reference Study ID Numbers: GO28888/BIG-3-13/SOLTI 1205/ABCSG 38.
Title: PI3K-Akt-mTOR pathway analysis to obtain further insight in the efficacy of everolimus in combination with exemestane in metastatic, ER-positive breast cancer: A Dutch breast cancer research group (BOOG) study

Dinja T Kruger¹, Karin Beelen², Connie R Jimenez¹, Maurice PHM Jansen³, Stefan Sleijfer³, Sabine C Linn² and Epie Boven¹. ¹VU University Medical Center, Amsterdam, Noord Holland, Netherlands; ²Netherlands Cancer Institute, Amsterdam, Noord-Holland, Netherlands and ³Erasmus University Medical Center, Rotterdam, Zuid Holland, Netherlands.

Body: Background
In patients with hormone receptor-positive breast cancer, activation of the PI3K-Akt-mTOR pathway is associated with resistance against endocrine therapy. Previous research has shown that genetic aberrations in this pathway occur frequently, including mutation and/or amplification in PI3K subunits or PI3K effectors as well as loss of lipid phosphatases (Fu X, et al. The Breast; 2013). Central review of the BOLERO-2 randomized phase III trial in which patients refractory to a non-steroidal aromatase inhibitor were randomized between exemestane combined with the mTOR inhibitor everolimus versus exemestane and placebo has shown a progression-free survival (PFS) of, respectively, 11.0 and 4.1 months [hazard ratio = 0.38 (95% confidence interval 0.31-0.48; log-rank P <0.0001)] (Yardley DA, et al. Adv Ther; 2013). The combination, however, is known to cause more adverse events and is associated with additional costs as compared to exemestane alone. In the present study we will explore whether there are biomarkers that might indicate which patients most likely benefit from co-targeting PI3K and ER pathways.

Trial design/Aims
This is a Dutch prospective, open-label, single-arm, investigator-initiated, multicenter trial in which approximately 30 hospitals will participate. A total of 175 patients will be included for baseline blood sampling and archival tumor tissue collection. From 50 patients, a fresh tumor biopsy is required at baseline and from 30 out of 50, another tumor biopsy will be collected upon progressive disease. Exploratory biomarker assessment includes immunohistochemistry (total and phosphorylated PI3K, AKT, mTOR, p70S6K and 4EBP1), tissue phosphoproteomics and circulating tumor DNA (mutations). The results of the biomarker analysis will be compared with clinicopathological characteristics and PFS.

Eligibility
Postmenopausal patients with hormone receptor-positive, HER2-negative, locally advanced or metastatic breast cancer, refractory to anastrozole or letrozole will be included. No previous treatment with exemestane or mTOR inhibitor for advanced disease is allowed and Informed consent must be signed before enrollment.

Statistical methods
Since the majority of the tests involve the use of new techniques, the study will be mainly explorative in design. The association between potential biomarkers and clinicopathological characteristics will be tested using Fisher exact test or the Mann-Whitney test. PFS curves will be drawn using the Kaplan-Meier method. PFS in association with potential biomarkers will be tested using Cox proportional hazard regression analysis.

Present and target accrual
Recently, the study has been opened for inclusion. A period of 2 years is planned for patient enrollment. Up to May 2014, two patients were included.

ClinicalTrials.gov identifier
NCT02109913

Financial support is received from Novartis, the Netherlands.
Title: Phase Ib dose allocation study of oral administration of lucitanib given in combination with fulvestrant in patients with estrogen receptor-positive and FGFR1-amplified or non-amplified metastatic breast cancer (INES)

Mario Campone1, Thomas Bachelot2, Fabrice André3, Chadi Saba4, Valérie Agrapart4, Marie-Jeanne Pierrat4, Frédéric Dubois4, Thibault Chesnel4 and Camille Poirot4.

1Institut de Cancérologie de l'Ouest – Centre René Gauducheau, Saint-Herblain, France; 2Centre Léon Bérard Centre de Lutte Contre le Cancer (CLCC) de Lyon, Lyon, France; 3Institut Gustave Roussy-Breast Cancer Unit 39 rue C Desmoulins, Villejuif, France and 4Institut de Recherche International Servier 53, rue Carnot, Suresnes, France.

Body: Background: Lucitanib is a potent, oral inhibitor of the tyrosine kinase activity of fibroblast growth factor receptors 1-3 (FGFR1-3), vascular endothelial growth factor receptors 1-3 (VEGFR1-3) and platelet-derived growth factor receptors α/β (PDGFRα/β). FGF aberrancy, as defined as FGFR1- or 11q- amplification, is a hallmark genomic alteration in breast cancer, observed at a frequency of up to 25% of patients and is strongly associated with luminal B type. Breast cancer patients with measurable disease and FGF aberrancy treated in the ongoing Phase 1/2 clinical trial of lucitanib monotherapy experienced an overall response rate of 50% (6 out of 12 patients). FGFR1-knock down was shown to decrease cell proliferation and reverse resistance to endocrine therapy in a FGFR1-amplified breast cancer cell line, hence supporting the idea of combining lucitanib with an endocrine agent such as fulvestrant, at the time of resistance. This has led to this Phase Ib study of lucitanib in combination with fulvestrant in metastatic breast cancer.

Trial design: INES is a multicenter, open-label, 2-part study to assess the tolerability of lucitanib in terms of Maximum Tolerated Dose (MTD) and Dose-Limiting Toxicities (DLTs) when administered with fulvestrant. A Continual Reassessment Method (CRM) will be used for the 1st part. A minimum of 3 patients will be enrolled at the initial dose level of 10 mg daily in combination with fulvestrant. Additional doses of 12.5 mg and 15 mg of lucitanib will be tested with the option of deescalating to 7.5 mg in case of DLTs. A minimum of 9 patients will be included at the MTD. In the 2nd part, 2 cohorts will be opened: fourteen FGF+ patients (FGFR1-or 11q- amplification), and fourteen non-amplified patients. All patients will receive fulvestrant 500 mg monthly and lucitanib at the recommended dose (RD) until unacceptable toxicity according to the investigator, disease progression or patient withdrawal. The main objective is to identify the Phase II RD when lucitanib is combined with fulvestrant. Secondary objectives include determination the Pharmacokinetic (PK) profile of lucitanib and metabolites; Measurement of tumour response; Description of the pharmacodynamic (PD) profile of lucitanib and investigation of any potential exposure dose-response relationships for safety, efficacy and PD.

Eligibility Criteria: Patients with estrogen receptor-positive, HER2 negative, breast cancer after progression or recurrence on prior therapy including fulvestrant. Patients should have ECOG performance status 0 or 1. Patients with uncontrolled hypertension are not eligible. For part 2, the presence of a metastatic site for biopsy to assess the presence of FGFR1- and/or 11q- amplification, which will be analysed centrally using FISH, is required.

Conclusion: INES is a phase Ib trial testing lucitanib in combination with fulvestrant in order to select the RD for phase II and seek preliminary efficacy signal in FGFR1- or 11q- amplified or non-amplified patients. As of June 2014, 3 patients have been enrolled in the 10 mg dose escalation cohort.
Title: OlympiA, Neo-Olympia and OlympiAD: Randomized phase III trials of olaparib in patients (pts) with breast cancer (BC) and a germline BRCA1/2 mutation (gBRCAm)

Mark Robson¹, Andrew Tutt², Judith Balmaña³, ¹², Bella Kaufman⁴, Judy Garber⁵, Charles Geyer⁶, James Ford⁷, Priyanka Sharma⁸, Mary Stuart⁹, Helen Mann⁹ and Peter A Fasching¹⁰,¹¹. ¹Memorial Sloan Kettering Cancer Center, New York, NY; ²King's College London School of Medicine and Institute of Cancer Research, London, United Kingdom; ³University Hospital Vall d'Hebron, Barcelona, Spain; ⁴Sheba Medical Center, Tel Hashomer, Israel; ⁵Dana-Farber Cancer Institute, Boston, MA; ⁶Virginia Commonwealth University, Massey Cancer Center, Richmond, VA; ⁷Stanford University School of Medicine, Stanford, CA; ⁸University of Kansas Medical Center, Westwood, KS; ⁹AstraZeneca, Macclesfield, Cheshire, United Kingdom; ¹⁰University Hospital, Erlangen, Germany; ¹¹German Breast Group, Neu Isenburg, Hessen, Germany and ¹²SOLTI Breast Cancer Research Group.

Body: Background  A Phase II study showed that the PARP inhibitor olaparib (400 mg bid; capsules) exerts antitumor activity in BC pts with a gBRCAm (Tutt et al Lancet 2010). Three Phase III trials of olaparib monotherapy have been initiated in BC pts with a gBRCAm: OlympiA (NCT02032823), Neo-Olympia (D081EC00005), OlympiAD (NCT02000622).

*Curative-intent surgery to be performed after 12 wks; pts will then receive olaparib 300 mg bid (Arm A), placebo (Arm B), or either weekly paclitaxel 80 mg/m² for 12 wks (then olaparib 300 mg bid) or olaparib 300 mg bid (Arm C). BICR, blinded independent central review; d, days; DDFS, distant disease-free survival; EFS, event-free survival; IDFS, invasive disease-free survival; ORR, objective response rate; pCR, pathological complete response; q, every; PFS2, time to second disease
For each trial, eligible pts will have a BRCAm and will undergo gBRCAm testing (Myriad Integrated BRACAnalysis®) as part of the trial. For OlympiA, pts must be at high risk of recurrence and have completed local treatment and either neoadjuvant (without pCR) or adjuvant chemotherapy. Neo-Olympia pts can have operable, locally advanced or inflammatory BC, must have a tumor >2cm by clinical exam (or >1cm by radiological exam) and have completed four cycles of anthracycline plus carboplatin without progression. OlympiAD pts can have TNBC or HER2– BC, and must have received prior anthracycline and taxane in the adjuvant or metastatic setting, and ≤2 chemotherapy lines for mBC. OlympiA pts will be treated for up to 12 months (m); efficacy will be assessed q3m up to 24m, then q6m up to 60m, then q12m. Neo-Olympia pts will be treated for 12 wks (w) pre-surgery, then for 40w post-surgery. In OlympiAD, PFS will be assessed by RECIST v1.1; radiologic exams will be performed at baseline, q6w up to 6m, then q12w until progression. In OlympiA and OlympiAD, IDFS and PFS will be analyzed using stratified log-rank tests; for Neo-Olympia, pCR rate will be analyzed with an adjusted logistic regression model. Primary analyses will be undertaken after 330 IDFS events (OlympiA), surgery (Neo-Olympia) and 230 PFS events (OlympiAD). Enrollment began in Mar 2014 for OlympiAD, Apr 2014 for OlympiA and is expected to begin in Q3 2014 for Neo-Olympia.

Body: Background: Endocrine therapy (ET) is the cornerstone treatment for HR–positive, HER2-negative breast cancer (BC) patients. The high response rates with ET in these patients are partially undermined by the resistance developed by most of them over time. On early disease recurrence/progression to AIs, the treatment options include other AI, estrogen-receptor antagonists or chemotherapy (being capecitabine one of the best options). Preclinical data suggest that ER+/HER2- BC are dependent on cyclin-dependent kinases 4/6 (CDK4/6) function; the inhibition of this target may be effective in delaying/reverting endocrine resistance. Palbociclib is an oral novel CDK4/6 inhibitor that seems to be synergistic with ET in preclinical and clinical studies.

Trial Design: This is an international (6 countries) randomized phase III study. Patients are randomized 1:1 to exemestane (25 mg daily) plus palbociclib (125 mg daily x3 weeks every 4 weeks) vs. capecitabine (1,250 mg/m² twice daily x2 weeks every 3 weeks). Postmenopausal patients with HR+/HER2- MBC are eligible if resistant to previous NSAI (letrozole or anastrozole) defined as: recurrence while on or within 12 months after the end of adjuvant treatment or progression while on or within 1 month after the end of treatment for MBC. Previous chemotherapy is permitted either in the (neo)adjuvant setting and/or as first line for MBC. Patients must have measurable disease according to RECIST 1.1 or lytic bone lesions in the absence of measurable disease. The primary objective is Progression-Free Survival (PFS); secondary objectives are overall survival, response rate, clinical benefit rate, response duration, safety, quality of life and biomarker's defined changes. The study will recruit 348 patients to detect a difference of 2.75 months in the median PFS (from 6 to 8.75 months; hazard ratio= 0.686), with a power of 80% and a 5% two sided significance level. The study started recruitment in March 2014 and 14 patients have been included so far (ClinTrials.gov reference NCT02028507).
Title: A phase I study of LDE225 in combination with docetaxel in patients with triple negative (TN) advanced breast cancer (ABC): GEICAM/2012-12 (EDALINE study)

Miguel Martin¹, Manuel Ruiz-Borrego², José M Trigo³, Silvia Antolin⁴, Jose A Garcia-Saenz⁵, Andres Hernandez⁶, Alberto Ocaña⁷, Federico Rojo⁸, Sara Lopez-Tarruella⁹, Jesus Corral², Nuria Ribelles³, Lourdes Calvo⁴, Fernando Moreno⁵, Rosalia Caballero⁶ and Eva Carrasco⁶. ¹Instituto de Investigacion Sanitaria Gregorio Maranon, Universidad Complutense, Madrid, Spain; ²Hospital Universitario Virgen del Rocio, Sevilla, Spain; ³Hospital Clinico Universitario Virgen de la Victoria, Malaga, Spain; ⁴Complejo Hospitalario Universitario A Coruña, A Coruña, Spain; ⁵Hospital Clinico San Carlos, Madrid, Spain; ⁶GEICAM, San Sebastian de los Reyes, Madrid, Spain; ⁷Complejo Hospitalario Universitario de Albacete, Albacete, Spain; ⁸Fundacion Jimenez Diaz, Madrid, Spain and ⁹Instituto de Investigacion Sanitaria Gregorio Maranon, Madrid, Spain.

Body: Background: LDE225 is a potent and selective oral inhibitor of Smo, a key component of the hedgehog (Hh) signaling pathway. Up-regulation of the Hh pathway is implicated in the genesis of a wide range of tumors including triple negative breast cancer. Here we report an ongoing phase I study exploring the combination of LDE225 with docetaxel in TN ABC patients to identify the Maximum Tolerated Dose (MTD) and the Recommended Phase II Dose (RP2D) (ClinicalTrials.gov Identifier: NCT02027376).

Trial Design: Eligibility criteria include patients with TN ABC candidates to receive treatment with docetaxel that have received a maximum of 3 prior chemotherapy regimens. Those patients with CNS involvement are also candidates if treated and clinically stable. Treatment consists of 21-day cycles with docetaxel 75mg/m² on day 1, every 21 day and LDE225 once daily. We use a standard 3+3 design in sequential cohorts (3 dose levels (DL) of LDE225: 400mg once daily (DL1), 600mg once daily (DL2), 800mg once daily (DL3); and a DL-1: LDE225 400mg once daily and docetaxel 60mg/m² every three weeks). The primary endpoint is the MTD and RP2D of the combination; secondary endpoints include evaluation of safety and tolerability, in addition to pharmacodynamic (PD) and pharmacokinetic (PK) studies. Patients are treated until radiologic or symptomatic progression or unacceptable toxicity occurs. PK will be performed to evaluate whether LDE225 influences the pharmacology of docetaxel. PD assessments include Hg gene expression signature associated to pathway activation in tumor samples and changes in Smo related biomarkers in skin and blood correlative samples. Efficacy will be measured in terms of time to progression and objective response rate. A minimum of 9 and a maximum of 18 patients will be included in this phase I. The study is approved by ERBs and Competent Authority and already recruiting patients (two patients included in DL1).
Title: A phase III study of abemaciclib (LY2835219) combined with fulvestrant in women with hormone receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) breast cancer (MONARCH 2)

Antonio Llombart, Masakazu Toi, Suzanne R Klise, Martin Frenzel, Edward M Chan and George W Sledge. 1Hospital Arnau de Vilanova, Valencia, Spain; 2Kyoto University, Kyoto, Japan; 3Eli Lilly and Company, Indianapolis, IN and 4Stanford University, Stanford, CA.

Body: Background: Abemaciclib (LY2835219), an oral drug administered twice daily on a continuous schedule, is a cell cycle inhibitor of both CDK4 and CDK6. In Study I3Y-MC-JPBA, abemaciclib demonstrated evidence of single agent activity in a tumor-specific cohort of patients with metastatic breast cancer (MBC) and a median of 7 prior therapies; all responses observed were in women with HR+ disease. Abemaciclib also demonstrated an acceptable safety profile both as a single agent and in combination with fulvestrant. Based on these results, abemaciclib has been entered into a Phase III study (MONARCH 2) in combination with fulvestrant for women with locally advanced or metastatic hormone receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) breast cancer.

Trial design: MONARCH 2 (NCT02107703) is a randomized, double-blind, placebo-controlled Phase III study of fulvestrant with or without abemaciclib for women with HR+, HER2- locally advanced (not amenable to curative treatment by surgery) or metastatic breast cancer. Patients will be randomized 2:1 (Arm A [abemaciclib plus fulvestrant]: Arm B [placebo plus fulvestrant] with stratification based on the nature of disease (visceral metastases versus bone only metastases versus other) and sensitivity to endocrine therapy (no prior endocrine therapy versus primary resistance versus secondary resistance). Abemaciclib (200 mg every 12 hours [Q12H] on Days 1 to 28 of a 28-day cycle) or placebo will be given orally and fulvestrant 500 mg will be administered intramuscularly on Days 1 and 15 of Cycle 1, then on Day 1 of Cycle 2 and subsequent cycles.

Eligibility criteria: Postmenopausal women with HR+, HER2- inoperable locally advanced or metastatic breast cancer who have either relapsed after prior endocrine therapy or have not received prior endocrine therapy are eligible. Patients are required to have either measurable disease or non-measurable bone only disease, adequate organ function and an Eastern Cooperative Oncology Group (ECOG) performance status (PS) of ≤1.

Specific aims: The primary objective of MONARCH 2 is to compare PFS between two treatment arms: abemaciclib plus fulvestrant versus placebo plus fulvestrant for women with HR+, HER2- locally advanced or metastatic breast cancer. Secondary objectives are to compare overall survival, objective response rate, clinical benefit rate, safety, pharmacokinetics and quality of life.

Statistical methods: The study has 90% power to detect an increase in PFS of approximately 42% (hazard ratio = .703). Assuming a median PFS of 6.5 mos. in the control arm, this corresponds to a 2.75 month increase in the median PFS to 9.25 mos. PFS and OS will be hierarchically tested to maintain an overall type I error rate of 2.5%.

Present accrual and target accrual: Target accrual is approximately 550 patients.

Contact information: For further information please contact 1-877-CTLILLY (1-877-285-4559).
Title: Master regulator (MR)-directed therapy in residual breast cancer patient derived xenografts (PDXs)

Kevin Kalinsky¹, Prabhjot Mundi¹, Dawn L Hershman¹, Eileen Connolly¹, Katherine D Crew¹, Hanina Hibshoosh¹, Andrea Calfiano¹ and Matthew Maurer¹. ¹Columbia University Medical Center, New York, NY.

Body: Background: Neoadjuvant chemotherapy (NACT) is standard of care in operable breast cancer (BC). There are no therapies that have demonstrated benefit in patients who failed to achieve a pathologic complete response (pCR). There remains an unmet need to identify appropriate targets in which to direct therapy in this high-risk population to decrease BC mortality. Computational approaches to reverse engineering of cell signaling networks from patient tumor-specific RNA expression data can identify key molecular dependencies that result in the malignant phenotype, i.e. MRs. These approaches out-perform traditional methods, such as identifying mutated or over-expressed genes, in determining true tumor dependencies. Successful targeting of MRs may be a means for rational selection of targeted drugs in the operable BC setting.

Trial Design: A single center pilot study that will accrue 35 subjects with BC who will have received standard NACT and at least 1.5 cm of residual disease. At the time of definitive surgery, resected tissue will be assessed for residual disease and then allocated. After reserving required tissue for pathologic diagnosis, 0.5 cm³ will be procured for xenografting and 0.5 cm³ will be flash frozen for RNA extraction. Tissue for xenografting is immediately sent to a Champions Oncology site for implantation. We will use fresh frozen tissue to perform RNA-seq. Previously validated computational algorithms at our center, including MARINa and VIPER, will be used to interrogate the expression data and identify the top MRs in individual tumors. Upon maturation of a Champions Oncology Tumor Graft model, the second generation expansion group will be divided into four cohorts. We plan to test two drugs that target tumor-specific MRs, one vehicle control, and one negative control (paclitaxel, as these tumors have demonstrated paclitaxel resistance) in each model.

Eligibility Criteria
1. Patients ≥18 years with newly diagnosed BC, deemed candidates for definitive surgery.
2. Subjects must have received standard NACT with taxane (paclitaxel or docetaxel; herceptin +/- pertuzumab if HER2+) and/or adriamycin/cytoxan.
3. Clinical or radiographic evidence of ≥1.5 cm of residual BC.
4. ECOG PS ≤2

Specific Aims:
1) To computationally infer MRs in individual patient tumors resistant to NACT
2) To determine if targeting MRs results in superior tumor growth inhibition in PDX models

Statistical Methods: In the PDX model, pre- and post-treatment tumor volume (TV) is calculated: TV= width² x length x 0.52, and is standardized as a tumor growth inhibition (TGI) percentage compared to the vehicle control. Since we anticipate the MR-directed arms will demonstrate a TGI (80%) twice that of the paclitaxel arm (40%), we have 80% power to detect a difference in 18 patients (one-sided alpha, 0.05). We assume a xenograft take-rate of 50% in the post-NACT setting and thus aim for an N of 35. Final data analysis will be adjusted using ANOVA.

Present and Target Accrual: 35 patients, projected to accrue in 18-24 months. Estimate based on number of locally advanced BC patients seen, competing studies, and likelihood of participation. The study will open in Fall 2014.
Title: Phase I/II trial of ruxolitinib in combination with trastuzumab in metastatic HER2 positive breast cancer

Kevin Kalinsky¹, Dow-Chung Chi¹, Shing Lee¹, Amy Tiersten², Della Makower³, Ellen Chuang⁴, Katherine D Crew¹, Dawn L Hershman, Jose Silva², Andrea Califano¹ and Matthew Maurer⁴. ¹Columbia University Medical Center, New York, NY; ²Icahn School of Medicine at Mount Sinai; ³Albert Einstein College of Medicine, Bronx, NY and ⁴Weill Cornell Medical Center, New York, NY.

Body: Background
Integrated analysis of whole genome RNAi screening with computationally reverse engineered interactome models identified IL6/JAK/STAT as a master regulator pathway essential for growth of ErbB2/HER2 positive breast cancer. Ruxolitinib (R), FDA-approved treatment for myelofibrosis, inhibits JAK1 and JAK2. The combination of R plus Trastuzumab (T) is synergistic in tumor growth inhibition in mouse xenografts of HER2 amplified breast cancer cell lines. These data provide a strong rationale for studying the efficacy of combination R and T in a clinical trial.

Trial Design
A multi-center, open-label, phase I/II (P1/2) trial of R plus T in HER2+ metastatic breast cancer (MBC) who have progressed on T-based therapy. P1 will be an adaptive design with 10 patients, using the time-to-event continual reassessment method. The recommended P2 dose (RP2D) will be used in a non-randomized, open-label P2 trial with 30 evaluable patients (pts). Given the anticipated limited overlapping toxicities, approximately 36 pts (range: 32-40) are expected for the P1/2. The duration of a treatment cycle will be 21 days. R will be taken orally twice a day continuously. The P1 dosing range will be 10-25 mg BID (dose level 0: 20 mg BID). T will be administered on Day 1 of each cycle at standard dosing. Objective Response Rate (ORR) will be assessed by imaging every 9 weeks. Blood samples will be obtained for biomarker analysis, pre-treatment, on-treatment on C2D1, and then at progression. Pre-treatment biopsies from archival tissue or new biopsy, on treatment biopsy on C2D1, and upon progression of disease will be discussed with pts with accessible disease.

Main Eligibility Criteria:
1. HER2 positive MBC
2. Progression on ≥2 HER2-directed therapy in metastatic setting, including Pertuzumab and T-DM1
3. Measurable or non-measurable disease
4. LVEF >50%.
5. No history of prior JAK2 inhibitor
6. No HIV-positive or active infection
7. No concurrent medications that are potent CYP3A4 inhibitor or inducer

Specific Aims
1. Primary: P1: MTD of combined R + T. P2: Progression Free Survival (PFS)
2. Secondary: a) Clinical: ORR, clinical benefit rate (CBR), and tolerability. Pts will be stratified by hormone receptor (HR) status to explore differences in efficacy between HR+ and HR-.
b) Explore potential predictive tumor and blood-based predictive biomarkers at baseline, on treatment, and progression: (tumor: pSTAT3 expression); serum: IL-6, IL-8, C-reactive protein; circulating tumor cell pSTAT3 expression; and tumor gene expression.

Statistical Methods
Assuming a historical PFS of 8 weeks with single-agent agent HER2-targeted therapy in HER2+ MBC after progressing on T-based therapy, we predict that pts receiving the combination of R plus T will have a PFS of at least 13 weeks. With a 2-sided alpha of 0.05, we have 80% power to detect a difference with 30 pts.

Target Accrual
Sample Size: 32-40 pts; projected over 2 years at 4 sites: Columbia, Einstein, Mount Sinai, and Cornell. Trial will start accruing July 2014.
Title: The B-YOND study: A phase II three-arm randomized trial of the combination of tamoxifen plus goserelin acetate with BYL719 or buparlisib (BKM120) in premenopausal patients with hormone receptor-positive/HER2-negative locally advanced or metastatic breast cancer

Yen-Shen Lu¹, Yeon Hee Park², Zhimin Shao³ and Roberta Valenti⁴. ¹National Taiwan University Hospital, Taipei, Taiwan; ²Samsung Medical Center, Seoul, Korea; ³Fudan University Cancer Hospital, Shanghai, China and ⁴Novartis Pharma AG, Basel, Switzerland.

Body: Background:
The incidence of breast cancer (BC) has been rapidly increasing in many countries in the last decades. In contrast to Western countries, approximately 50% of BC patients in Eastern countries are premenopausal, with hormone receptor-positive (HR+) disease, or luminal subtype by molecular classification. Benefit from the most recent advances in endocrine treatments for patients with HR+ BC is currently confined to postmenopausal women. For premenopausal metastatic BC (MBC) tamoxifen and/or ovary ablation/suppression remain the recommended first-line therapies for metastatic disease through category 2 evidence, calling for further clinical investigations.

In the context of growing evidence of the role of PI3K/AKT/mTOR pathway inhibition in enhancing and extending the benefit of endocrine therapies in HR+ MBC pre-clinical and clinical models, the B-YOND study is a phase II, three-arm randomized trial aimed at exploring the PI3K inhibitors buparlisib and BYL719 in combination with tamoxifen in the context of ovarian suppression in premenopausal patients with MBC.

Design & Objectives:
Premenopausal women with HR+/HER2-negative locally advanced or MBC who a) are newly diagnosed or b) recurred during or after adjuvant treatment with tamoxifen monotherapy, and received no endocrine treatment in the metastatic setting, will be randomized to receive tamoxifen plus goserelin (control arm, Arm 3) or the same combination with buparlisib (Arm 2) or BYL719 (Arm 1) until progression. Stratification based on previous treatment with tamoxifen and presence of liver and/or lung metastasis will be applied. Primary objective is the efficacy comparison of Arm 1 vs Arm 3 and Arm 2 vs Arm 3 in terms of 9-month progression free survival (PFS) rate. Secondary objectives include additional efficacy evaluations (median PFS, overall response rate, clinical benefit), safety and tolerability, quality of life, and pharmacokinetics.

Statistical Methods:
Based on previous reports, the estimated proportion of patients who are alive without progression at 9 months is 50% for the control arm (P0=0.50), and we hypothesize that this proportion is 75% for both experimental arms (P1=0.75). Using a two-sided 0.05 level of significance for both the comparisons [Arm 1 vs Arm 3; Arm 2 vs Arm 3], with an overall type-I error not greater than 0.10, with 80% power, the estimated patient numbers needed is 58 patients for each arm. With an assumption that approximately 10% patients will be lost to follow-up, a total of 192 patients will need to be randomized to the three treatment arms in 1:1:1 ratio.

Accrual
This study will be open for recruitment in Taiwan, South Korea, China, Hong Kong and Thailand and potentially extended to additional Eastern countries. Enrollment started in May 2014 and will last for an estimated period of 18 months.
Title: A phase 3, open-label, randomized, parallel, 2-arm multi-center study of the oral PARP inhibitor BMN 673 versus physician’s choice in germline BRCA mutation subjects with locally advanced and/or metastatic breast cancer (EMBRACA study)

Jennifer K Litton¹, Joanne L Blum², Wolfgang Eiermann³, Young-Hyuck Im⁴, Miguel Martin⁵, Lida Mina⁶, Henri Roché⁷, Hope S Rugo⁸, Frances Visco⁹, Charlie Zhang¹⁰, Nathalie A Lokker¹⁰ and Debra L Lounsbury¹⁰. ¹MD Anderson Cancer Center, Houston, TX; ²Baylor Sammons Cancer Center, Texas Oncology, US Oncology, Dallas, TX; ³Interdisziplinares Onkologisches Zentrum Munchen, Munich, Germany; ⁴Samsung Medical Center, Seoul, Korea; ⁵Hospital General Universitario Gregorio Marañón, Madrid, Spain; ⁶Indiana University School of Medicine, Indianapolis, IN; ⁷Institut Universitaire du Cancer Toulouse, Toulouse, France; ⁸UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; ⁹National Breast Cancer Coalition, Washington, DC and ¹⁰BioMarin Pharmaceutical Inc, Novato, CA.

Body: Background: Poly-ADP-ribose polymerase (PARP) represents a family of enzymes of which at least two (PARP1 and PARP2) play important roles in DNA repair. PARP inhibition induces synthetic lethality in tumor cells bearing mutations in the genes encoding breast cancer susceptibility gene 1 (BRCA 1) and breast cancer susceptibility gene 2 (BRCA 2), both of which are key components in the pathway of homologous recombination DNA repair. BMN 673 is the most potent preclinical PARP inhibitor described to date with the highest efficiency at trapping PARP-DNA complexes (Murai et al, 2014). BMN 673 is a novel and highly potent PARP inhibitor and has shown promising single-agent anti-tumor efficacy in several tumor types in an ongoing Phase 1/2 clinical study.

Methods: The purpose of this multi-center, international, open-label, 2:1 randomized Phase 3 trial (EMBRACA) is to compare the safety and efficacy of BMN 673 versus protocol-specific physician’s choice treatment (capecitabine, eribulin, gemcitabine or vinorelbine) in subjects who have locally advanced and/or metastatic breast cancer with germline BRCA mutations. The primary objective of the study is to compare progression free survival (PFS) of subjects treated with BMN 673 as a monotherapy relative to those treated with protocol-specific physician’s choice treatment. Secondary objectives include objective response rate (ORR), overall survival (OS), safety and pharmacokinetics of BMN 673. Exploratory objectives include duration of response (DOR) and health-related quality of life assessment. Patients may be eligible if they are 18 years or older, have histologically or cytologically confirmed carcinoma of the breast, locally advanced and/or metastatic disease appropriate for systemic single cytotoxic chemotherapy, documentation of a deleterious or pathogenic germline BRCA1 or BRCA2 mutation, ≤ 2 prior chemotherapy-inclusive regimens for locally advanced and/or metastatic disease, prior treatment with a taxane and/or anthracycline in the adjuvant or metastatic setting, ECOG performance status ≤ 1, and no prior platinum treatment for metastatic disease. Patients (n=429) will be randomized 2:1 to receive either BMN 673 oral capsules once daily (1.0 mg/day) in 21-day cycles or protocol-specific physician’s choice treatment. All eligible subjects will receive study drug treatment until disease progression or unacceptable toxicity. This trial is enrolling patients from the United States, Europe, Israel, Asia/Pacific, and South America (NCT01945775).
**Title:** A Phase 2, randomized, open-label, multicenter, safety and efficacy study of oral lucitanib in patients with metastatic breast cancer with alterations in the FGF pathway

Maysa Abu-Khalaf¹, Ingrid Mayer², Jason B Litten³, Mitch Raponi³, Andrew R Allen³, Lajos Pusztai¹ and Carlos L Arteaga². ¹Yale Cancer Center, New Haven, CT; ²Vanderbilt-Ingram Cancer Center, Nashville, TN and ³Clovis Oncology, Inc, San Francisco, CA.

**Body:** BACKGROUND: Lucitanib is a potent, oral inhibitor of the tyrosine kinase activity of Fibroblast Growth Factor Receptors 1-3 (FGFR1-3), Vascular Endothelial Growth Factor Receptors 1-3 (VEGFR1-3) and Platelet-Derived Growth Factor Receptors A/B (PDGFRα/B). Aberrant FGF signaling, as defined as \( \text{FGFR1} \) and/or 11q amplification, is a hallmark genomic alteration in breast cancer, observed at a combined frequency of up to 25% of patients. Breast cancer patients with measurable disease and aberrant FGF signaling treated in the ongoing Phase 1/2 clinical trial of lucitanib monotherapy experienced an ORR of 50% and a DCR of 100%. This compelling clinical activity has led to the initiation of a global clinical development program for lucitanib in breast cancer.

TRIAL DESIGN: The current study is comparing PFS for doses of lucitanib (10 or 15 mg daily) in patients with FGF-aberrant metastatic breast cancer after failure of currently available standard therapies. Approximately 160 patients will be randomized 1:1 to the 10 mg and 15 mg daily dosing groups and stratified by FGF pathway alteration (\( \text{FGFR1} \) or 11q amplification) and prior anti-VEGF therapy (yes or no). \( \text{FGFR1} \) and 11q (containing the FGF ligands 3, 4, and 19) amplification is determined locally for patient enrolment and confirmed by central laboratory fluorescent in situ hybridization (FISH) testing. A total of 130 PFS events provides 80% power at a 2-sided significance level of 0.05 to detect a hazard ratio of 0.60 for comparing the 10 mg and 15 mg dose groups. Secondary objectives are ORR, DoR, DCR, OS, PROs, safety and population PK. Exploratory endpoints include tissue and blood-based biomarkers that may be predictive of response or primary resistance to treatment with lucitanib.

ELIGIBILITY CRITERIA: Histologically or cytologically confirmed FGF-aberrant metastatic breast cancer relapsed or refractory to approved standard available treatment. ECOG 0 or 1. Normal organ function. Patients with uncontrolled hypertension are excluded.
Title: A phase 2, 2-stage, 2-cohort study of the oral PARP inhibitor BMN 673 in patients with germline BRCA mutation and locally advanced and/or metastatic breast cancer (ABRAZO study)

Nicholas C Turner¹, Judith Balmana², Susan M Domchek³, Frances Visco⁴, Charlie Zhang⁵, Nathalie A Lokker⁶, Debra L Lounsbury⁵ and Mark E Robson⁶. ¹Royal Marsden Hospital and Institute of Cancer Research, London, United Kingdom; ²Vall Hebron Institute of Oncology, Barcelona, Spain; ³Basser Research Center for BRCA, University of Pennsylvania, Philadelphia, PA; ⁴National Breast Cancer Coalition, Washington, DC; ⁵BioMarin Pharmaceutical Inc, Novato, CA and ⁶Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY.

Body: Background: Poly-ADP-ribose polymerase (PARP) represents a family of enzymes of which at least two (PARP1 and PARP2) play important roles in DNA repair. PARP inhibition induces synthetic lethality in tumor cells bearing mutations in the genes BRCA1 and BRCA2, both of which are key components in the homologous recombination DNA double-strand breaks repair pathway. BMN 673 is the most potent preclinical PARP inhibitor described to date with the highest efficiency at trapping PARP-DNA complexes (Murai et al, 2014). BMN 673 has shown promising single-agent anti-tumor efficacy in several tumor types in an ongoing Phase 1/2 clinical study.

Methods: The purpose of this Phase 2 trial (ABRAZO) is to evaluate the safety and efficacy of BMN 673 in patients with locally advanced or metastatic breast cancer with a deleterious germline BRCA 1 or BRCA 2 mutation. This study is an open-label, 2-stage, 2-cohort Phase 2 study using a Southwest Oncology Group (SWOG) 2-stage design. Eligible subjects will be assigned to either Cohort 1 (n=70) or 2 (n=70) based on prior chemotherapy exposure for metastatic disease: Cohort 1) Subjects who have previously responded to a platinum-containing regimen for metastatic disease with disease progression > 8 weeks following the last dose of platinum; or Cohort 2) Subjects who have received > 2 prior chemotherapy regimens and who have had no prior platinum therapy for metastatic disease. The primary objective is to determine the objective response rate (ORR) of BMN 673 as a single agent for each cohort. The secondary objectives of the study are to determine the following for each cohort: clinical benefit rate (CBR), duration of response (DOR), progression free survival (PFS), and overall survival (OS). Health-related quality of life assessment is an exploratory objective. Patients may be eligible if they are 18 years or older, have histologically or cytologically confirmed carcinoma of the breast, locally advanced and/or metastatic disease, deleterious or pathogenic germline BRCA1 or BRCA2 mutation, prior chemotherapy for metastatic disease based on the above Cohort 1 or Cohort 2 inclusion criteria, ECOG performance status ≤ 1, and no central nervous system (CNS) metastasis except adequately treated brain metastasis documented by baseline CT or MRI scan that has not progressed since previous scans and that does not require corticosteroids for management of CNS symptoms. Eligible patients will receive BMN 673 oral capsules once daily (1.0 mg/day) continuously in 21-day cycles until disease progression or unacceptable toxicity. This trial is enrolling patients from the United States and European countries (NCT02034916).
**Body: Background:**

Inflammatory breast cancer (IBC) is an aggressive form of breast cancer that accounts for 3 to 5% of all invasive breast tumors in the United States. IBC possesses an increase of proangiogenic factors including vascular endothelial growth factor (VEGF), basic fibroblast growth factor (bFGF), and platelet derived growth factor (PDGF) as compared with non-IBC. In particular, FGF family receptors play a critical role in tumorigenesis, morphogenesis, and inducers of angiogenesis. Dovitinib (TKI258) is an oral tyrosine kinase inhibitor with in vitro IC\textsubscript{50} values of approximately 10 nmol/L against FGFR1-3, VEGFR1-3, and PDGFR. These structurally related receptors are important for the growth and survival of endothelial cells during tumor angiogenesis.

**Trial Design:**

This is a single institution, single arm phase II study. Patients receive a single daily oral dose of dovitinib 500 mg for 5 consecutive days, followed by a 2-day rest period (5 days on/2 days off schedule).

**Eligibility:**

Patients have histological confirmation of breast carcinoma with a clinical diagnosis of IBC based on presence of inflammatory changes in the involved breast, including diffuse erythema and edema (peau d’orange). Pathological evidence of dermal lymphatic invasion should be noted but is not required for diagnosis. HER2-negative. ECOG PS 0-2. Baseline MUGA or echocardiogram scans with LVEF of > 50%. Normal hematology, liver and kidney function laboratory studies. Patients must have received at least 2 chemotherapy lines for metastatic disease and have relapsed.

**Research Hypothesis:**

Dovitinib has antitumor activity in patients with HER2-negative advanced IBC.

**Specific Aims:**

Primary objective: to determine the disease control rate (CR, PR, and SD). Secondary objective: to evaluate safety profile. Exploratory biomarkers: circulating tumor cells (CTC), CTC undergoing EMT, and cancer stem cells

**Statistical Methods:**

The primary endpoint is the six-month disease control rate (ORR) as defined by RECIST 1.1. A response is anyone who experiences SD, CR or PR in the first 6 months. We will conduct this study with Simon’s two-stage design using the mini-max criterion and the response rate will be estimated accordingly. It is assumed that dovitinib will have a target ORR of 30%. An ORR of 10% or lower is considered a failure based on the typical ORR with a second line regimen for IBC and the new regimen will be rejected under this circumstance. When the probability of accepting a "bad" regimen (i.e. response rate ≤ 10%) is 0.05 and the probability of rejecting a "good" regimen (i.e. response rate ≥ 30%) is also 0.10, Simon’s design to minimize the maximum sample size requires 22 patients in the first stage. If two or less patients respond to the treatment, the trial will be stopped and the regimen will be declared as ineffective. If at least three of the first 22 patients respond to the treatment, 11 additional patients will be entered in the study to reach a total of 33 patients. By the end of the study, the new regimen will be rejected if response rate is less than or equal to 6 out of 33 patients and will be accepted otherwise.

**Present Accrual and Target Accrual:**

A total of 22 patients were accrued. Target accrual is 33 patients.
Title: A randomized, multicenter, phase II study of ipatasertib (Ipat, GDC-0068), an inhibitor of Akt, in combination with paclitaxel (Pac) as front-line treatment for patients (pts) with metastatic triple-negative breast cancer (TNBC)

Steven J Isakoff¹, Sung-Bae Kim², Seock-Ah Im³, Rebecca A Dent⁴, Tiffany A Traina⁵, Vicente Valero⁶, Cristina Saura⁷, Sreeni Yalamanchili⁸, Premal Patel⁸ and Mafalda Oliveira⁷. ¹Massachusetts General Hospital Cancer Center, Boston, MA; ²Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; ³Seoul National University College of Medicine, Seoul, Korea; ⁴Seoul National University College of Medicine, Seoul, Korea; ⁵Memorial Sloan Kettering Cancer Center, New York, NY; ⁶University of Texas MD Anderson Cancer Center, Houston, TX; ⁷Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain and ⁸Genentech, San Francisco, CA.

Body: Background: The PI3K/Akt pathway is often activated in TNBC through loss of PTEN expression, low INPP4B expression, and/or increased AKT3 amplification. Activation of Akt may then lead to chemoresistance; thus, inhibition of Akt signaling may result in improved efficacy of chemotherapy in TNBC. Ipat (GDC-0068) is a potent ATP-competitive small molecule inhibitor of all Akt isoforms. In preclinical breast cancer models, the combination of Ipat with taxanes enhanced efficacy, and in a Phase Ib study, the combination of Ipat with Pac was well-tolerated and resulted in clinical responses.

Trial Design: This is a randomized, double-blinded, placebo controlled, international, multicenter, Phase II study designed to estimate the efficacy and safety profile of Ipat combined with Pac versus placebo combined with Pac in pts with metastatic TNBC. Pts will receive Ipat or placebo 400 mg orally once daily on Days 1 to 21 of each 28-day cycle with Pac 80 mg/m² on Days 1, 8, and 15 of each 28-day cycle. Treatment will continue until disease progression, intolerable toxicity, withdrawal, or study completion. Pts will then be followed every 3 months for survival. Archival tumors will be assessed for PTEN expression by immunohistochemistry.

Key Eligibility: Pts ≥ 18 years, ECOG 0 or 1, with histologically documented TNBC that is inoperable locally advanced or metastatic and not amenable to curative resection are eligible. Additional eligibility criteria include availability of a tumor specimen, measurable disease per RECIST v1.1, and adequate hematologic and organ function within 14 days of study. Any previous therapy for TNBC is excluded, except for prior neoadjuvant or adjuvant chemotherapy and/or radiation completed 6 months prior to study. Pts with known brain or spinal cord metastases are also excluded.

Objectives: The primary objective is progression-free survival (PFS) in all TNBC pts and in TNBC pts with PTEN-low tumors. Secondary objectives include estimation of overall survival (OS), objective response rate (ORR), duration of ORR, safety, pharmacokinetics (PK), patient-reported outcomes (PROs), and biomarkers.

Statistical Methods: Approximately 120 pts will be randomized 1:1 and stratified by prior adjuvant/neoadjuvant treatment including chemotherapy and/or radiation (yes vs. no), disease free interval from last dose of chemotherapy (≤ 12 months vs. > 12 months), and tumor PTEN status (low/null vs. moderate vs. high). Primary and secondary efficacy analyses will include all randomized pts, grouped by treatment at randomization. Kaplan–Meier curves will be produced for analyses of PFS, OS, and duration of response, and stratified log rank tests will be used to compare treatments.

Accrual: This study is open for accrual.
Title: Circulating tumor DNA in plasma as a surrogate for tumor biopsy to identify tumor genetic alterations in patients with multi-focal metastatic breast cancer

Mary D Chamberlin¹, Todd W Miller¹, Jennifer R Bean¹, Richard J Barth¹, Kari M Rosenkranz¹, Jonathan D Marotti¹, John M Gemery¹ and Jiang Gui¹. ¹Dartmouth-Hitchcock Medical Center, Lebanon, NH.

Body: Background: While effective targeted therapies exist for patients with ER/PR + (anti-estrogens) and HER2+ (anti-HER2 agents) disease, and some triple-negative cancers respond to DNA-damaging chemotherapy, many patients eventually exhibit disease refractory to all standard breast cancer therapies, particularly in the metastatic setting. Expanding catalogs of tumor-targeted therapies are being developed, and tumor genetics are playing an increasing role in patient selection. However, tumors can exhibit intra- and inter-tumor genetic heterogeneity. If a biopsied tumor is not genetically reflective of all tumors within a patient, then the optimal therapy may be overlooked. Identifying targetable genetic changes for which there are drugs, using non-invasive procedures, will be an increasing challenge for medical oncologists. One way to potentially overcome this issue is through cell-free circulating tumor DNA, which is detectable in the bloodstream. This study represents the first step in this important process: evaluating plasma DNA as a potential route to non-invasive identification of genetic mutations in patients with metastatic breast cancer with several tumors.

Design: Patients with new or progressive metastatic breast cancer with >=3 sites of biopsy-able disease are enrolled. Large bore, large volume blood draw for PT/ INR and plasma DNA will be obtained. Primary tumor will be biopsied if present. Biopsies of >=3 tumors in >=2 different organ sites will be required. Tumor histology and ER/PR/her2 status will be determined. Tumor tissue and plasma will undergo DNA sequencing.

Eligibility: Measureable new or progressive metastatic breast cancer by CT and bone scan or PET scan. >=3 sites of disease with >=2 organ sites appropriate for biopsy. Prior therapy allowed, but all specimens must be obtained prior to change in therapy.

Primary objective: To determine whether the genetic mutations in plasma DNA are reflective of the genetic mutations present in biopsies of all tumors.

Secondary objectives: To determine A) the amount of plasma DNA required to capture all somatic genetic mutations in tumor samples, and B) the extent of genetic heterogeneity between primary and metastatic tumors.

Primary endpoint: Rate of genetic concordance between plasma DNA and >=3 tumor within each patient.

Present accrual: 2 Target accrual: 10.

Title: Trastuzumab in HER2-negative early breast cancer as adjuvant treatment for circulating tumor cells (CTCs) (Treat CTC)

Michail Ignatiadis¹, Carlo Messina², Saskia Litiere², Dimitris Mavroudis³, Christian Dittrich⁴, Anthony Kong⁵, Wolfgang Janni⁶, Christos Sotiriou¹, Martine Piccart¹, Jean-Yves Pierga⁷ and Brigitte Rack⁸. ¹Institut Jules Bordet, Université Libre de Bruxelles, Belgium; ²European Organization for Research and Treatment of Cancer (EORTC), Belgium; ³University Hospital of Heraklion, Greece; ⁴LBI-ACR VIEnna – LBC-TO, Kaiser Franz Josef-Spital, Austria; ⁵Oxford University Hospitals NHS Trust – Churchill Hospital, United Kingdom; ⁶Universitätsklinikum Ulm, Germany; ⁷Institut Curie, France and ⁸Ludwig-Maximilians-University, Munich, Germany.

Body: Background:
The presence of Circulating Tumor Cells (CTCs) in metastatic breast cancer (BC) is associated with worse clinical outcome. Recent data showed an association between CTC(s) detection and reduced disease-free and overall survival in early disease. Patients with persisting CTC(s) after (neo)adjuvant chemotherapy might benefit from additional systemic treatment. Trastuzumab is a part of the standard of care for patients with HER2-positive BC. Recent data have reinforced the hypothesis that the therapeutic effect of trastuzumab depends on immune-related mechanisms. It has been demonstrated that trastuzumab eliminated CTC(s), irrespective of the HER2 status of the primary tumor and of CTC(s) and this was associated with improved relapse-free survival (Bozionellou et al, Clin Cancer Res 2004, Georgoulias et al Ann Oncol 2012).
The Treat CTC trial is designed to explore the effect of trastuzumab in patients with HER2-negative early BC and persisting CTC(s) after (neo)adjuvant chemotherapy and surgery.

Trial Design:
Treat CTC trial is a multicentre (6 countries, 92 centers) European randomized phase II trial, sponsored by the EORTC and run under the BIG umbrella. It will assess the efficacy of trastuzumab in eliminating persisting CTC(s) after the completion of (neo)adjuvant chemotherapy and surgery in patients with HER2-negative early BC. Eligible patients will be randomized in a 1:1 ratio to either 6 cycles of trastuzumab or observation.

Eligibility criteria:
- Adequately excised HER2-negative early BC
- Evidence of CTC(s) detection using the CellSearch technology after completion of (neo)adjuvant chemotherapy
- Completion of adjuvant chemotherapy for node-positive disease or neoadjuvant chemotherapy with residual invasive disease in breast or lymph nodes (no complete pathological response)

Specific aims:
The primary objective is to evaluate whether trastuzumab decreases the detection rate of CTCs in patients with HER2-negative primary BC by comparing the trastuzumab treated arm to the observation arm. Furthermore, clinical outcomes as measured by Recurrence Free Interval (RFI), Invasive Disease Free Survival (IDFS), Disease Free Survival (DFS) and Overall Survival (OS) between the trastuzumab and observation arms will be compared.

Present accrual and target accrual:
It is estimated that 2175 women will be registered to include 174 patients eligible for randomization in a 1:1 ratio. Accrual is expected to be completed in 2 years. Treat CTC started patient screening in May 2013 in Belgium, in March 2014 in Germany and in June 2014 in France. An update of the proportion of patients screened versus patients randomized will be presented during SABCS.

Methods:
The primary test will be a one-sided test to compare the trastuzumab arm to the observation arm for the CTC(s) detection rate at week 18 (superiority test). The comparison for the primary endpoint will be performed on the intention-to-treat population using a one-sided test with overall α of 0.1. The odds ratio and its confidence interval will be estimated using a logistic regression model. The comparison of RFI, IDFS, DFS and OS will be done using a two-sided test in a proportional hazards model for cause specific hazard, adjusted for the stratification factors.
Title: The DETECT-study concept: Treatment based on the phenotype of circulating tumor cells in HER2-negative metastatic breast cancer

Bernadette AS Jaeger¹, Susanne Albrecht¹, Fabienne Schochter¹, Carola A Melcher², Carsten Hagenbeck², Thomas WP Friedl¹, Brigitte Rack³, Volkmar Müller⁴, Peter A Fasching⁵, Wolfgang Janni¹ and Tanja Fehm². ¹University Hospital Ulm, Ulm, Germany; ²University Hospital Duesseldorf, Duesseldorf, Germany; ³University Hospital LMU-Munich, Munich, Germany; ⁴University Hospital Hamburg-Eppendorf, Hamburg, Germany and ⁵University Hospital Erlangen, Friedrich-Alexander University Erlangen-Nuremberg, Comprehensive Cancer Center Erlangen-EMN, Erlangen, Germany.

Body: Background: The prognostic impact of circulating tumor cells (CTC) in metastatic breast cancer (MBC) is well demonstrated. The role of CTCs in predicting specific treatment response and the importance of CTC phenotypes for therapeutic decisions will be investigated within the DETECT-study concept.

Trial Design and eligibility criteria: The DETECT studies are prospective, multicenter, open-label clinical trials designed for patients with HER2-negative MBC and evidence of CTCs in the peripheral blood. DETECT III is a two-arm study for patients with HER2-positive CTCs, randomized to physician’s choice therapy (chemotherapy or endocrine treatment) with or without additional HER2-targeted treatment with lapatinib. DETECT IV combines two single-arm studies aimed at patients with HER2-negative CTCs. Postmenopausal patients with hormone-receptor-positive MBC will be treated with the mTOR-inhibitor everolimus in combination with an endocrine therapy of physician’s choice (everolimus cohort), whereas patients with triple-negative or hormone-receptor-positive MBC and indication to chemotherapy will receive eribulin (eribulin cohort).

Specific aims: The primary objective of the trials is to estimate the clinical efficacy of treatments, assessed by the CTC clearance rate for DETECT III and by progression-free survival (PFS) for DETECT IV.

Methods: Prevalence of CTCs at various time points as well as the HER2 status of CTCs are assessed using the FDA-approved CellSearch System (Veridex, USA). After immunomagnetic enrichment with an anti-EpCam-antibody, cells were labelled with anti-CK8/18/19 and anti-CD45 antibodies to distinguish epithelial cells from leucocytes. A fluorescein conjugate antibody with anti-CK-Fluorescein Isothiocyanate (FITC) was used for HER2 phenotyping. The cut-off for CTC-positivity was 1 CTC and for HER2 1 CTC with strong HER2-staining (+++). Survival endpoints will be estimated using the Kaplan-Meier method.

Present and target accrual: Overall, about 2000 patients with HER2-negative MBC will have to be screened for CTCs to be able to recruit 228 patients with HER2-positive CTCs for DETECT III (which started in February 2012), 400 patients with HER2-negative CTCs for DETECT IV- everolimus cohort (which started in December 2013) and 120 patients for DETECT IV- eribulin cohort (which will start in the second half of 2014). 907 patients have been recruited for CTC screening until June 2014.

Perspectives: One screening for CTCs offers different treatment options for patients with HER2-negative MBC and evidence of CTCs within the DETECT-study concept. DETECT III is the first study to investigate a personalized targeted treatment based on the phenotype of CTCs. The addition of a HER2-targeted therapy in case of HER2-positive CTCs is innovative and in case of success will lead to new treatment strategies in MBC. DETECT IV complements DETECT III with regard to additional therapy indications.
Body: Background:
Circulating tumor DNA (ctDNA) has been proposed as a biological surrogate of the repertoire of molecular aberrations in cancer patients. The genetic information derived from the analysis of ctDNA may be therefore employed as biomarker for diagnosis, prognostication, therapy response monitoring and assessment of genetic mechanisms of resistance. We have initiated a prospective study in a population of BRCA1-mutation carrier at high risk of either relapse and/or new cancer growth. The CirCA01 study is based on the combination of (i) on the clinical side, the systematic inactivation of the TP53 gene by mutations in BRCA1-related cancers, whatever the histological type and the organ of origin, and (ii) on the bench side, an original assay that allows to detect any TP53 mutation in plasma with exquisite sensitivity.

Methods:
CirCA01 is a national prospective study, opened in several cancer centers in France (Institut Curie, Gustave Roussy, Centre Léon Bérard, Centre Eugène Marquis) and funded by the French Ministry of Health (PHRCK1369250N). Inclusion criteria are: patients with no evidence of any invasive tumor mass at inclusion (clinical and, if any, radiological exams), carriers of known germline BRCA1 deleterious mutation (a personal history of cancer being not mandatory), age ≥ 30 years for patient with previous history of cancer or age ≥ 40 years for patient without previous history of cancer, written informed consent. Main exclusion criteria are: patient presenting with invasive tumor masses (e.g. stage IV cancer or localized cancer not yet surgically removed), carriers of germline BRCA1 variant of unknown significance, carriers of germline BRCA2 deleterious mutation or variant, individuals with a low risk of BRCA1-related tumor growth, i.e. women who underwent prophylactic bilateral mastectomy, annexectomy or contralateral prophylactic mastectomy after breast cancer. 200 BRCA1 mutation carriers will be enrolled and followed up regularly, as per national guideline for high-risk patients. Fresh plasma samples will be collected at each follow-up visit to the hospital and will be used to detect any mutation in TP53 exons and flanking non-translated regions by a "digital NGS"-based technique. (NCT registration ongoing).

Results: Correlation with patients outcome will allow to report whether TP53 ctDNA detection may be used as (i) a new screening test that can be repeated easily in BRCA1-carriers with no evidence of tumor growth (ii) a new diagnostic test in BRCA1-carriers who present a clinical or radiological abnormality (typically ACR class 3 mammograms): (A) diagnosis of the malignant vs benign nature of the abnormality, based on TP53 mutation levels, (B) differential diagnosis of a new cancer growth vs relapse of a previously treated cancer based on TP53 mutation characterization (different vs similar TP53 mutations).
Title: Phase II study on radiofrequency ablation in stage 0 and I breast cancer without extensive intraductal components

Shigeru Imoto¹, Shinji Nagamine², Shunichi Ito³, Hitoshi Tsuda⁴, Masayuki Yoshida⁵, Mitsuhiro Tozaki⁶, Satoshi Morita⁷ and Takayuki Ueno¹. ¹School of Medicine Kyorin University, Japan; ²Okinawa Red Cross Hospital, Japan; ³Rinku General Medical Center, Osaka, Izumisano, Japan; ⁴National Defense Medical College, Japan; ⁵National Cancer Center Hospital, Japan; ⁶Kameda Medical Center, Japan and ⁷Kyoto University Graduate School of Medicine, Kyoto, Japan.

Body: Background: Screening mammography makes it possible to identify small size of breast cancer (BC) and minimize surgical management. Previously we reported about a multi-center cohort study on radiofrequency ablation (RFA) in early breast cancer (ASCO2012 #1119). Although various devices and ablation procedure were attempted, 5-year’s recurrence-free survival of ipsilateral breast tumor was 96% in 425 cases of T1BC treated with RFA alone (the mean follow-up, 50 months). To validate complete pathological ablation in BC, we started a non-randomized phase II study in 2013 (UMIN000013836). Eligibility criteria: Unilateral BC patients with stage 0 (TisN0M0) or I (T1N0M0 or T1N1miM0) are eligible. Written informed consent is obtained. Tumor diameter of 2cm or less should be diagnosed by ultrasound and MR mammography. BC with diffuse calcification, extensive intraductal components, or multiple tumors is excluded. Methods: RFA is performed by Cool-tip RF ablation system (Covidien, USA). The needle electrode is inserted into the center of referent tumor under ultrasound guidance. The first ablation is started at an initial electrical power level of 5W for 1 min and the power is increased at 10W for 1 min. After then, it is increased in steps of 10W from every minute until rapid elevation of tissue impedance. The second ablation is allowed by physician’s discretion. One month later, ablated tissue is collected by core needle biopsy or vacuum-assisted breast biopsy. Cell viability is examined by central review of independent pathologists using tumor specimens stained with hematoxylin–eosin and nicotinamide adenine dinucleotide (NADH) diaphorase. In case of complete ablation, breast irradiation and adjuvant therapy will be performed. In case of incomplete ablation, partial mastectomy should be recommended. Aims: The primary endpoint is complete ablation rate. The secondary endpoints are deformity after RFA, relapse-free survival and overall survival for 10 years. Two-step design is used for statistical evaluation. Finally, 32 patients will be needed. Present accrual: As of April 2014, 16 patients were enrolled. One patient was ineligible because of macrometastasis in a sentinel node. Of 13 eligible patients who underwent pathological examination, one patient had viable cancer cells with NADH diaphorase staining. We also investigate optimal histological examination of cell viability and adequate image diagnosis after RFA.
Title: Will chest wall and regional nodal radiotherapy post mastectomy or the addition of regional nodal radiotherapy to breast radiotherapy post lumpectomy reduce the rate of invasive cancer events in patients with positive axillary nodes who convert to ypN0 after neoadjuvant chemotherapy? NSABP B-51/RTOG 1304 a phase III trial

Eleftherios P Mamounas1,2, Hanna Bandos1,3, Julia R White4,5, Thomas B Julian1,6, Atif J Khan1,7, Simona F Shaitelman6,8, Mylin A Torres1,9, Susan A McCloskey1,10, Frank A Vicini1,11, Patricia A Ganz1,10, Soonmyung Paik1,12, Nilendu Gupta4,13, Joseph P Costantino1,3, Walter J Curran, Jr4,9 and Norman Wolmark1,6. 1National Surgical Adjuvant Breast and Bowel Project (NSABP), Pittsburgh, PA; 2UF Health Cancer Center at Orlando Health; 3University of Pittsburgh Graduate School of Public Health, NSABP Biostatistical Center, PA; 4Radiation Therapy Oncology Group; 5Ohio State University; 6Allegheny Cancer Center at Allegheny General Hospital; 7Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; 8University of Texas MD Anderson Cancer Center, Houston, TX; 9Winship Cancer Institute of Emory University, Atlanta, GA; 10University of California, Los Angeles, CA; 11Saint Joseph Mercy Oakland (21st Century Oncology); 12Severance BioMedical Science Institute and Yonsei University College of Medicine and 13Ohio State University, James Cancer Hospital.

Body: Background
This phase III randomized post-neoadjuvant chemotherapy trial will evaluate if chest wall and regional nodal XRT (CWRNRT) after mastectomy or whole breast irradiation (WBI) with RNRT after breast-conserving surgery significantly reduces the rate of events for invasive breast cancer recurrence-free interval (ICBR-FI) in patients who present with histologically positive axillary nodes but become histologically negative axillary nodes after neoadjuvant chemotherapy. Secondary aims are OS, LRR-FI, DRFI, DFS-DCIS, and second primary cancer. HYPOTHESIS: Can We Use Tumor and Nodal Response to Neoadjuvant Chemotherapy in Order to Individualize the Use of L-R XRT?
Correlative science will examine the effect of RT by tumor subtype, molecular predictors of outcome for patients with residual disease, and the development of predictors of degree of reduction in loco-regional recurrence.

Methods
Eligible patients with clinical T1-3, N1 breast cancer with pathologic axillary nodal involvement (positive FNA or core needle biopsy) must complete ≥12 weeks of neoadjuvant chemotherapy (anthracycline and/or taxane-based regimen). HER2-positive patients must receive neoadjuvant trastuzumab or other anti-HER2 therapy. After neoadjuvant chemotherapy either breast-conserving surgery or mastectomy will be performed. At the time of surgery, all removed axillary nodes must be histologically free from cancer. 3 or more histologically negative sentinel nodes are acceptable to determine axillary nodal involvement. ER/PR and HER-2 neu status before neoadjuvant chemotherapy is required. All patients will receive additional required systemic therapy.
Site radiation credentialing with a facility questionnaire and case benchmarking is required. Randomization for mastectomy patients will be to no CWRNRT or CWRNRT and for breast-conserving surgery patients to WBI or WBI RNRT.

Statistical Considerations
1636 patients will be enrolled over 5 years with definitive analysis at 7.5 years. The study is powered at 80% to test the main hypothesis that RT reduces the annual hazard rate of events for IBCR-FI by 35% for an absolute risk reduction in the 5-year cumulative rate of 4.6%. Analysis will be on intent-to-treat with 3 formal interim analyses at 43, 86, and 129 events, with a 4th/final analysis at 172 events. Current accrual is 37. (as of 6-10-14)
736 enrolled patients will be evaluated with targeted patient-reported outcome instruments focusing on the effect of RT. Patient assessments will be prior to randomization and then at 3, 6, 12, and 24 months.

Contact Information
Study protocol information can be found under the protocol-specific web page on the CTSU member web site https://www.ctsu.org. Title: HIOB trial - Hypofractionated whole-breast irradiation preceded by intraoperative radiotherapy with electrons as anticipated boost

Roland Reitsamer¹, Gerd Fastner², Michael Kopp² and Felix Sedlmayer². ¹University Hospital Salzburg, Breast Center Salzburg, Paracelsus Medical University, Salzburg, Austria and ²University Hospital Salzburg, Paracelsus Medical University, Salzburg, Austria.

Body: ClinicalTrials.gov Identifier: NCT01343459

Brief background discussion:
The commonly accepted standard fractionation schedule for whole breast irradiation (WBI) consists of 25 fractionations with single fractional doses of 2 Gy, resulting in cumulative doses of 50 Gy to the whole breast. Hypofractionation trials from UK and Canada demonstrated a similar outcome in local control and cosmesis compared to conventional fractionation. The combination of IOERT boost and hypofractionation was not yet evaluated.

Trial design:
Prospective one-armed multi-center trial - ISIORT 01

Eligible patients are treated with hypofractionated whole breast irradiation (WBI) of 40.5 Gy in 2.7 Gy per fraction for 15 days, preceded by an intraoperative electron boost (IOERT) to the tumor bed of 10 Gy (90% isodose) during breast conserving surgery.

Eligibility criteria:
Inclusion criteria:
Invasive breast cancer
Age 35 years and older
T1/T2, N1/N2, G1 - G3
Hormone receptor and Her 2 status: no limitations

Exclusion criteria:
Non-invasive breast cancer
Age less than 35 years
T3/T4, N2/N3
Neoadjuvant chemotherapy

Aim of the study:
To assess the effectiveness of IOERT in combination with hypofractionated WBI in terms of in-breast tumor control and cosmetic outcome, by matching or exceeding the best published results for annual LR rates in 3 different age groups in reference to an upper limit (exceeding = inferiority) and a lower limit (undershooting = superiority) which were estimated on the basis of the existing literature as follows:

Age 35 – 40 years:
Upper limit (best published evidence): 1.2 % (EORTC 22881- Boost trial)
Lower limit (commonly expected dimension): 0.72 % (CONSORT trial)

Age 41 – 50 years:
Upper limit (best published evidence): 1.2 % (EORTC 22881- Boost trial)
Lower limit (commonly expected dimension): 0.72 % (CONSORT trial)

Age over 50 years:
Upper limit (best published evidence): 0.7 % (EORTC 22881- Boost trial)
Lower limit (commonly expected dimension): 0.4 % (START B trial)

Primary endpoint:
Proof of superiority or iso-effectiveness.

Secondary endpoints:
Acute toxicity (CTC- toxicity scoring system) and late toxicity (LENT SOMA scoring system), cosmetic results (Van Limbergen - Score), DFS, OS.
Statistical methods:
Sequential Probability Ratio Test (SPRT):
As a consequence of best published analyses for this patient selection, stopping rules for annual local recurrence rates are defined as follows:
Age group 35-40: H0: p1 <= 0.72% vs H1: p1 > 0.72% with p2 = 4.0%
Age group 41-50: H0: p1 <= 0.72% vs H1: p1 > 0.72% with p2 = 2.4%
Age group 51+: H0: p1 <= 0.4% vs H1: p1 > 0.4% with p2 = 1.4%
H0-Hypothesis means no superiority to standard regimen.
H1-Hypothesis means superiority of HIOB against best published evidence.
Present accrual and target accrual:
Start date: January 2011
Estimated enrollment: 1500 patients
542 patients recruited by March 2014
10 international institutions recruiting.
Title: Fulvestrant alone versus fulvestrant and everolimus versus fulvestrant, everolimus and anastrozole: A Phase III randomized, placebo-controlled trial in postmenopausal patients with hormone-receptor-positive stage IV breast cancer: SWOG-Clinical Trials Initiative (CTI)* S1222

George Somlo1, William Barlow2, Halle Moore3, Julie Gralow4, Anne Schott5, Daniel Hayes6, Peter Kuhn7, James Hicks8, Danika Lew9, Debu Tripathy10 and Gabriel Hortobagyl11. 1City of Hope Cancer Center, Duarte, CA; 2SWOG Statistical Center, Seattle, WA; 3Cleveland Clinic Foundation, Cleveland, OH; 4University of Washington, Seattle, WA; 5University of Michigan, Ann Arbor, MI; 6University of Michigan, Ann Arbor, MI; 7University of Southern California, Los Angeles, CA; 8Cold Spring Harbor Laboratory, Cold Spring Harbor, NY; 9SWOG Statistical Center, Seattle, WA; 10MD Anderson Cancer Center, Houston, TX and 11MD Anderson Cancer Center, Houston, TX.

Body: BACKGROUND: The median survival for women with hormone-receptor-positive (HR+) stage IV metastatic breast cancer (MBC) is 36 months. Strategies to improve outcome for postmenopausal women, include combinations of aromatase inhibitors (AIs) with either the estrogen receptor downregulator fulvestrant, or with the PI3kinase/AKT/mTOR signal inhibitor everolimus, as this pathway has been implicated as a mediator of resistance to endocrine therapies. However, fulvestrant 500 mg has not been tested in combination with everolimus alone, or in combination with everolimus and an AI.

SPECIFIC AIMS/TRIAL DESIGN: S1222 (NCT02137837) is a randomized phase III double-blinded, placebo-controlled clinical trial and is currently accruing. Patients receive fulvestrant (500 mg IM every 2 weeks for 3 doses, then monthly) on all arms, everolimus 10 PO daily (Arms 2 and 3, placebo Arm 1), and anastrozole 1 mg daily (Arm 3), or placebo (Arms 2 and 1). The co-primary objectives are to compare progression-free survival (PFS) between fulvestrant and everolimus (Arm 2) vs. fulvestrant (Arm 1), and fulvestrant, everolimus, and anastrozole (Arm 3) vs. fulvestrant (Arm 1). Additional objectives include comparison of PFS between Arms 2 and 3, and overall survival (OS), response and clinical benefit rates, toxicities, feasibility, compliance, and OS among the study arms.

Translational research goals are to test molecular determinants of response in circulating tumor cells (CTCs), assess a previously piloted CTC-Endocrine Therapy Index (CTC ETI), perform CTC-Next Generation Sequencing Analysis (CTC-NGS), and NGS on cancer tissue and germ line DNA.

ELIGIBILITY CRITERIA: Postmenopausal women with histologically confirmed de novo or newly relapsed stage IV MBC, with HER2-negative and HR-positive (≥1% positive nuclear staining) features, with either measurable, or evaluable disease are eligible. Previous neoadjuvant/adjuvant therapy allowed, but adjuvant anti-HR therapy must have been completed ≥ 12 months prior to enrollment.

STATISTICAL METHODS/TARGET ACCRUAL: This is a parallel randomized design with equal allocation to the three arms: (1) fulvestrant + placebo for everolimus + placebo for anastrozole; (2) fulvestrant + everolimus + placebo for anastrozole; (3) fulvestrant, everolimus, and anastrozole. PFS is the primary outcome. There are two coprimary hypotheses: (1) Arm 2 versus Arm 1; and (2) Arm 3 versus Arm 1, each will be tested at α = 0.025 (2-sided). Arm 2 versus Arm 3 is a secondary comparison. Sample size computations are based on accrual of 33 patients per month for 24 months resulting in a computed accrual total of 792. We estimate that the final analysis will occur 24 months after the last patient is accrued, an average followup of 36 months at the time of the final analysis with an expected trial duration of 4 years.

*SWOG-CTI manages the non-federally funded components of SWOG under The Hope Foundation. The study is supported by AstraZeneca and Novartis Pharmaceuticals Corp.

**Title:** A phase 2 study of neoadjuvant goserelin and letrozole for premenopausal women with estrogen receptor positive HER2 negative stage 2 and 3 breast cancer

Andre Mattar\(^1\), Rodrigo Goncalves\(^2\), Matthew J Ellis\(^2\) and Roberto Hegg\(^1\). \(^1\)Hospital Perola Byington, São Paulo, SP, Brazil and \(^2\)Washington University, School of Medicine, St Louis, MO.

**Body:**

**Background:** More than half of premenopausal women with breast cancer have tumors that are estrogen receptor (ER) positive. Despite this, there has been limited utilization of neoadjuvant endocrine therapy in that setting.

**Trial Design:** A Phase 2 study in premenopausal women (Age>18) with tumor size>2cm and locally advanced tumor, ER positive (Allred 6-8), HER2 negative, breast cancer who are not considered candidates for breast conservation surgery (BCS) or are borderline for BCS. Patients will be treated with a LHRH-A in combination with letrozole for a period of 4 weeks. At the end of 4 weeks, patients will undergo biopsy of the tumor for Ki67 assessment along with a serum estradiol (E2) level to confirm adequate hormone suppression.

Patients will then fall into one of 3 groups:

1. Postmenopausal (E2<10pg/ml) and Ki67 ≤ 10%
   These patients will remain on letrozole for 16-18 weeks followed by definitive surgery. Patients with a PEPI-0 and continued estradiol suppression will be offered surgical oophorectomy, continued letrozole and no chemotherapy (CT).

2. Postmenopausal (E2<10pg/ml) and Ki67>10%
   These patients will be designated endocrine therapy resistant and be offered neoadjuvant CT. Patients who decline neoadjuvant CT should be offered immediate surgery.

3. Premenopausal (E2 ≥ 10pg/ml)
   There is a failure of the LHRH-A to fully suppress estradiol levels at one month, treatment decisions will be individualized.

**Specific aims**

1. To determine the pathological complete response (pCR) rate to CT in patients with a Ki67>10% at one month, despite a fully suppressed estradiol level.

2. To determine the PEPI-0 rate in patients whose estradiol is fully suppressed at both 4 weeks and 16 weeks and whose 4 week tumor Ki67<10%.

3. In patients with a PEPI-0 tumor to determine the acceptability of management with surgical oophorectomy with continued oral letrozole and no CT.

**Statistical methods:**

The study design was chosen assuming the expectation for the efficacy of neoadjuvant CT in premenopausal women with ER+ breast cancer is low, with a pCR rate in the range of 5%. Our hypothesis is that patients with tumors resistant to endocrine therapy will be enriched for sensitivity to CT to a level typical of patients with ER negative disease (20%). Thus, the trial was designed so that at a 0.1 significance level, there would be a 90% chance of detecting a pCR rate >20% when the true pCR rate >5%. A 90% binomial confidence interval (CI) for the true pCR rate will be constructed. We anticipate approximately 20% of patients will have a 4 week Ki67 > 10%. A sample of 235 eligible patients will be required to obtain 35 with a 4-week post treatment Ki67 value >10 % and estradiol level <10 pg/ml who are willing to switch to neoadjuvant CT.

We anticipate that 75% of patients will have a 4-week Ki67 <10% along with estradiol <10pg/ml. Based upon the sample size needed, there would be 175 patients who complete 16 weeks of neoadjuvant endocrine therapy. We estimate at least 20% of the patients with a Ki67 <10% at 4 weeks will be in the PEPI 0, Stage 0/1 group after surgery. A 90% binomial CI will be constructed for the proportion of these who choose to forego CT.

**Accrual:** Open June 2014. Target=235.
Title: A pilot and phase II study of entinostat and anastrozole/tamoxifen in women with triple negative breast cancer (TNBC) to evaluate biomarkers and surrogates for response

Saranya Chumsri¹, Gauri Sabnis¹, Nancy Tait¹, Jane Lewis¹, Emily Bellavance¹, Susan Kesmodel¹, Steven Feigenberg¹, Katherine RH Tkaczuk¹, Peter Ordentlich³, Martin J Edelman² and Angela H Brodie¹. ¹University of Maryland Greenebaum Cancer Center, Baltimore, MD; ²University of New Mexico Cancer Center, Albuquerque, NM and ³Syndax Pharmaceuticals, Inc, Waltham, MA.

Body: Background: Triple negative breast cancer (TNBC) is an aggressive form of breast cancer that lack ER, PR, and HER2. TNBC is inherently resistant to endocrine therapy (ET) such as aromatase inhibitor (AI) and tamoxifen. Previous studies suggested that the loss of ER/PR expression in TNBC is due to epigenetic silencing. We have demonstrated histone deacetylase inhibitor (HDACi), entinostat, can induce expression of functional ER and render TNBC sensitive to ET both in vitro and in vivo (Sabnis et al. Cancer Research 2011). Furthermore, the combination of entinostat and AI can induce prolonged tumor regression and significantly reduce lung metastasis in vivo.

Trial Design: This is a single arm phase I/II study of entinostat in combination with ET. There are 2 cohorts in this study: cohort 1 – operable stage I-II TNBC, cohort 2 – metastatic and unresectable locally advanced TNBC. For ET, anastrozole will be used in postmenopausal women and tamoxifen in premenopausal women. The treatment regimen is: entinostat started on day 1 followed by ET on day 4. In cohort 1, paraffin embedded tissue from core needle biopsy and surgical specimens will be collected. In cohort 2, biopsies before and after 15-29 days of treatment are required.

Eligibility Criteria: Female age ≥ 18 with ECOG PS ≤ 2 and TNBC defined as ER and PR < 1% with no HER2 overexpression. Cohort 1 includes pts with operable stage I-II and cohort 2 includes pts with metastatic and unresectable locally advanced with ≤ 2 prior lines of chemotherapy who have accessible tumors for biopsies, excluding bone only metastasis.

Specific Aims: To determine ER expression as well as the percentage change in proliferation index (Ki67) after treatment. Moreover, safety and tolerability of the combination given either in neoadjuvant or metastatic setting will be evaluated. Response is defined as ≥ 50% reduction in Ki67 AND ≥ 1% ER-positivity OR pathologic complete response in the post-treatment surgical specimens.

Statistical Methods: For the pilot phase, a 3+3 cohort design is employed. The Simon’s two-stage design is used in the phase II. The total sample size for the phase II is 32 with 12 and 20 pts in the first and second stage respectively. The study will be terminated if there is no response among the first 12 pts. If ≥ 1 response in these 12 pts is observed, then 20 more pts will be accrued. The combination will be considered promising, if ≥ 4 out of 32 pts have a response. This design yields 87% power. The probability of early stopping and declaring that this combination has no sufficient activity is 0.54, if the true success rate is 5% and 0.07 if the true response rate is 20%. If the true proportion of pts with Ki67 reduction combined with ER up-regulation is 0.20, the probability of concluding that the drug has sufficient activity is 0.87 and 0.07 if the true proportion is 0.05. To allow about 10% inevaluable, the phase II trial will accrue 35 eligible pts. Therefore, the total target accrual is 41 pts.

To date, there are a total of 7 pts enrolled. Accrual is currently ongoing. Please contact ntait@umm.edu for further information.
**Title:** Alliance A011106: ALTernate approaches for clinical stage II or III Estrogen Receptor positive breast cancer NeoAdjuvant TrEatment (ALTERNATE) in postmenopausal women: A phase III study

Cynthia X Ma, Vera Suman, A Marilyn Leitch, Souzan Sanati, Katherine DeSchryver, Gary W Unzeitig, Paul Haluska, Mark Watson, Olwen Hahn, Jo Anne Zujewski, Kelly Hunt, Eric P Winer, Cliff A Hudis and Matthew J Ellis.

**Body:**

Neoadjuvant endocrine therapy (ET) in patients (pts) with locally advanced estrogen receptor positive (ER+) breast cancer (BC) improves breast conservation rate, and importantly offers an opportunity for individualized assessment of tumor responsiveness to ET to guide subsequent treatment. Previous neoadjuvant ET trials demonstrated that pathologic tumor size (pT), axillary lymph node status (N), and tumor Ki67 value at surgery predicted risk of relapse. Preoperative endocrine prognostic index (PEPI) was therefore developed to assign risk scores based on these factors. Modified PEPI 0, defined by pT1-2 N0 Ki67< 2.7%, was associated with extremely low risk of recurrence without adjuvant chemotherapy. In addition, high Ki67 post 2-4 weeks (wks) of neoadjuvant ET identified resistant tumors with poor outcome.

ALTERNATE trial is a three-arm phase III neoadjuvant/adjuvant ET trial designed to achieve two primary objectives. The first is to prospectively validate that modified PEPI 0 predicts > 95% relapse-free survival (RFS). The second is to determine whether fulvestrant (F), or fulvestrant (F) plus anastrozole (A), is superior to A in inducing a higher rate of modified PEPI 0. Secondary objectives include assessing RFS for pts with endocrine resistant tumor, defined by Ki67 > 10% at 4 or 12 wk, disease progression, or modified PEPI non-0, and pathologic responses of resistant tumors to neoadjuvant chemotherapy. Correlative studies include degrees of Ki67 suppression and ER level post treatment. In addition, ongoing research sequencing studies of DNA and RNA will be performed to contrast sensitive vs resistant tumors.

During the first phase of the trial, 1200 pts are randomized 1:1:1 to the F, A or F/A. This provides an 82% chance, 1-sided alpha 0.025 chi-square test to detect at least 10% difference in modified PEPI 0 rate comparing F or F/A with A. While waiting for result of analysis, the A arm will continue for the 2nd phase enrollment. Only the F-containing arm(s) superior over A will be continued to the 2nd phase.

During the 2nd phase, an additional 540 pts in each arm is estimated to obtain 317 pts with PEPI score 0. This will have a 90% chance, with a one-sided alpha=0.025 nonparametric Brookmeyer-Crowley type one sample survival test, rejecting that 5 year RFS rate is 95%. The maximum sample size is 2820 pts.

Eligible pts include postmenopausal women with newly diagnosed clinical stage II or III ER+ (Allred score 6-8) HER2- BC. Tumor biopsy is required at baseline, 4 wk, and surgery for central Ki67 analysis. Treatment decision is individualized based on 4 wk Ki67 and modified PEPI score. Pts with Ki67 > 10% at 4 wk are switched to chemotherapy. Pts with a modified PEPI score of 0 are recommended not to receive chemotherapy, but continue the assigned ET for 1.5 years followed by 3 years of A.

This trial is currently accruing pts through CTSU. This research is supported in part by NCI BIQSFP, and grants from Breast Cancer Research Foundation, Genentech, and the Investigator-Sponsored Study Program of AstraZeneca. The Clinical Trials.gov Identifier: NCT01953588.
Title: Prospective multicenter study evaluating the effect of impaired tamoxifen metabolization on efficacy in breast cancer patients receiving tamoxifen in the neo-adjuvant or metastatic setting - The CYPTAM-BRUT 2 trial

Body: Background
Tamoxifen is commonly used to treat and prevent hormone receptor positive breast cancers. This drug is metabolized into more active metabolites by liver enzymes such as cytochrome P450 (CYP) enzymes. Endoxifen is considered to be the principal active metabolite of tamoxifen. As CYP enzymes are highly polymorphic in humans, endoxifen plasma levels are modulated by the patient’s genotype. It, however, is not yet clear if lowered endoxifen plasma levels have an effect on tamoxifen efficacy. This is the first prospective study where the association between endoxifen plasma concentrations, multiple CYP-genotypes and clinical outcome in postmenopausal patients treated with tamoxifen is investigated.

Trial Design
CYPTAM-BRUT 2 is a prospective multi-center open label, single-arm, non-randomized observational study. Postmenopausal women with measurable, estrogen receptor positive breast cancer receiving tamoxifen as neo-adjuvant or as first-line metastatic treatment are included in this study. The objective treatment response and clinical benefit are observed to investigate the efficacy of 20 mg tamoxifen daily. Patients are allowed to have started tamoxifen before inclusion but not more than three months. Further, if more than twelve months have passed after completion of the adjuvant therapy prior endocrine therapy in the adjuvant setting is allowed. Patients receiving neo-adjuvant tamoxifen will be assessed no more than four months after starting with tamoxifen.

The primary endpoint is a statistical association between steady-state endoxifen plasma concentrations and the objective response rate (ORR) after 3-6 months of tamoxifen, under the assumption that the relationship is linear with an odds ratio (OR) of 1.49 per 10 nmol/L. Using available data on endoxifen concentrations, this OR is chosen to reflect an improvement from 10% ORR in the lowest endoxifen quartile to 30% in the highest endoxifen quartile when the overall ORR is around 18%. To have 90% power at a 5% significance level, 180 patients have to be included into the study. The main secondary study endpoint is the relation between endoxifen plasma concentrations and clinical benefit (CR+PR+SD at 6 months). The study has to include 270 patients to detect a statistically significant association with endoxifen with 90% power at a 5% significance level, assuming an OR of 1.28 per 10 nmol/L. This OR is chosen to reflect an improvement of clinical benefit at 6 months from 30% in the lowest endoxifen quartile to 50% in the highest endoxifen quartile (overall clinical benefit around 39%). For both endpoints the RECIST criteria are used. Other endpoints are progression-free survival, tolerability of tamoxifen treatment and the association between CYP2D6 genotype and clinical outcome.

Patient accrual
Patients from 22 participating centers in Belgium and Switzerland are included in this trial. In May 2014, the predefined sample size of 270 patients was reached. Follow-up of the last patients will continue until all required data are obtained (i.e blood samples and response evaluation).
Title: E2112: A randomized phase III trial of endocrine therapy plus entinostat/placebo in patients with hormone receptor-positive advanced breast cancer

Roisin M Connolly1, Fengmin Zhao2, Kathy D Miller3, Amye J Tevaarwerk4, Lynne I Wagner5, Min-Jung Lee6, Judy Murray1, Robert Gray2, Richard L Piekarsz7, Jo Anne A Zujewski7 and Joseph A Sparano8. 1Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD; 2Dana-Farber Cancer Institute, Boston, MA; 3Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN; 4University of Wisconsin Carbone Cancer Center, Madison, WI; 5Northwestern University Feinberg School of Medicine, Chicago, IL; 6National Cancer Institute, Bethesda, MD and 7Cancer Therapy Evaluation Program (CTEP), National Cancer Institute, Bethesda, MD.

Body: Background:
Epigenetic alterations in the genome, including abnormal DNA methylation and histone hypoacetylation, initiate and promote cancerous changes. A potential mechanism of resistance to endocrine therapy in breast cancer involves changes in gene expression secondary to epigenetic modifications, which might be modulated with the use of histone deacetylase (HDAC) inhibitors such as entinostat. Results from ENCORE 301, a phase II study evaluating the addition of entinostat to the steroidal aromatase inhibitor (AI) exemestane in patients with hormone receptor (HR)-positive advanced breast cancer who had experienced disease progression on a non-steroidal AI (NSAI), showed a significant improvement in progression-free survival (PFS), the primary endpoint, and overall survival (OS), an exploratory endpoint. Based on the OS results, entinostat has been designated a Breakthrough Therapy by the FDA when used in combination with exemestane in HR-positive advanced breast cancer.

Trial design:
E2112 is a multicenter randomized double-blind placebo-controlled phase III study (NCT02115282) enrolling patients with advanced HR-positive, HER2-negative breast cancer who have experienced disease progression on a NSAI (n=600). Patients will receive exemestane 25mg po daily and entinostat/placebo 5mg po every week (28 day cycle). Staging every 12 weeks.

Eligibility Criteria:
Postmenopausal women and men (≥ 18 years), ECOG performance status 0-1, locally advanced/metastatic invasive adenocarcinoma of the breast: ER/PR-positive, HER2-negative, measurable or non-measurable (20% cap) disease. Disease progression after NSAI use in the metastatic setting OR relapse while on or within ≤ 12 months of end of adjuvant NSAI therapy. Prior CDK inhibitor or everolimus permitted, but not exemestane or fulvestrant. One prior chemo permitted in metastatic setting.

Specific Aims:
Both PFS (defined by central review) and OS are primary endpoints, and the study is designed to show an improvement in either PFS or OS. Secondary endpoints include: Safety and tolerability, objective response rate, changes in lysine acetylation status in peripheral blood mononuclear cells, patient-reported symptom burden and treatment toxicities, adherence.

Statistical Methods:
One-sided type 1 error 0.025 split between two hypotheses tests: 0.001 for PFS test and 0.024 for OS. PFS is tested in the first 360 pts, 88.5% power to detect 42% reduction in the hazard of PFS failure (median PFS 4.1 to 7.1 months); OS is tested in all 600 pts, 80% power to detect 25% reduction in the hazard of death (median OS 22 to 29.3 months)

Present and Targeted Accrual: This study was activated in March 2014 and accrual is anticipated to complete in 40 months.

Funding: ECOG-ACRIN Cancer Research Group (ECOG-ACRIN), Cancer Therapy Evaluation Program (CTEP) at the National Cancer Institute, and Syndax Pharmaceuticals.
Title: A phase II study with orteronel as monotherapy in patients with androgen receptor (AR) expressing metastatic breast cancer (MBC)

Denise A Yardley¹, Suzanne F Jones², Nancy W Peacock³, Mythili Shastry², Robyn R Young⁴, Andre M Kallab⁵ and Howard A Burris III¹. ¹Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN; ²Sarah Cannon Research Institute, Nashville, TN; ³Tennessee Oncology, PLLC, Nashville, TN; ⁴Center for Cancer and Blood Disorders, Fort Worth, TX and ⁵Northeast Georgia Medical Center, Gainesville, GA.

Body: Background: Androgen Receptor (AR) signaling is a new target present in and under evaluation in all breast cancer subtypes. AR expression is noted in 70%-90% of primary breast tumors, up to 75% of all breast cancer metastases and is associated with resistance to endocrine therapy. Orteronel, an oral, selective, nonsteroidal inhibitor of androgen synthesis, is being developed as an endocrine therapy for hormone-sensitive cancers. In preclinical studies, orteronel suppresses sex hormone levels in blood and hormone-dependent malignant tissue. This study will evaluate the safety and efficacy of orteronel in the treatment of AR+ MBC.

Study Objectives: This phase II trial is designed to determine the response rate and disease control rate (CR+PR+SD at 6 mo) following treatment with orteronel in pts with AR+ MBC. Two groups will be evaluated: Cohort 1 will include pts with AR+, triple negative (TN) (ER-/PR-/HER2-) MBC, and Cohort 2 will include pts with AR+, ER+ and/or PR+ MBC (may be HER2+ or HER2-). Secondary objectives include evaluation of PFS and OS, safety and tolerability, as well as evaluation of changes in serum levels of total and free testosterone, sex hormone binding globulins (SHBG), adrenocorticotropic hormone (ACTH), dehydroepiandrosterone sulfate (DHEA-S), cortisol and estradiol during orteronel treatment. As an exploratory objective, archived tumor tissue will be analyzed for the presence of phosphatidylinositol 3-kinase (PIK3CA) mutations and loss of phosphatase and tensin homolog (PTEN).

Eligibility: Pts ≥18 years with AR+ (≥10% staining by immunohistochemistry) MBC, either TN or ER+ and/or PR+, are eligible. TNBC pts must have had 1-3 prior chemotherapy regimens in the advanced setting and ER+ and/or PR+ pts must have had 1-3 prior hormonal therapies and ≥1 chemotherapy regimen in the advanced setting. HER2+ pts must have received ≥2 lines of HER2-directed therapies. Additional eligibility criteria include: ECOG PS 0-2; adequate bone marrow and organ function, including left ventricular ejection fraction of ≥50%.

Trial Design: Six pts will be enrolled and treated with orteronel in the lead-in phase to confirm safety and tolerability. In the absence of any safety concerns, subsequent pts will be enrolled to either Cohort 1 or Cohort 2 (described above). Cohort 1 will contain 31 pts with AR+ TNBC and Cohort 2 will contain 55 pts with AR+ ER+ and/or PR+ MBC. All pts will receive 300 mg orteronel PO BID over a 4 week cycle. Pts will be evaluated with CT scans every 2 cycles and treatment will continue until disease progression or unacceptable toxicity. Response rate and disease control rate will be presented as the point estimate along with 95% confidence interals calculated using both asymptotic normal approximation and exact binomial methods. Simon’s two-stage design will be applied using alpha=0.10 and power=0.80 for each cohort. Blood samples will be collected at baseline, on Cycle 2 Day 1, Cycle 4 Day 1, and at the end of treatment to evaluate serum total and free testosterone, SHBG, ACTH, DHEA-S, cortisol, and estradiol levels. Archival tumor samples will be collected for exploratory PTEN and PIK3CA biomarker evaluations. This trial is currently enrolling and has a total accrual goal of 86 pts.
**Title:** A phase II open label study of everolimus in combination with anti-estrogen therapy in hormone receptor-positive HER2-negative advanced breast cancer

Denise A Yardley\(^1\), Mythili Shastry\(^2\), Laura M DeBusk\(^2\), Howard A Burris III\(^1\) and John D Hainsworth\(^1\). \(^1\)Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN and \(^2\)Sarah Cannon Research Institute, Nashville, TN.

**Body:** **Background:** Hormone receptor positive (HR+) breast cancer, defined as estrogen receptor and/or progesterone receptor positive, accounts for 70% of invasive breast cancers. While most HR+ tumors initially respond to anti-estrogen therapy, resistance, linked to crosstalk between cell signaling and signal transduction pathways, subsequently develops in almost 100%. Preclinical data has shown that the PI3K/Akt/mammalian target of rapamycin (mTOR) pathway is activated in long-term estrogen-deprived and aromatase inhibitor-resistant breast cancer cells. It is hypothesized that in this group of endocrine-resistant patients (pts), resistance to anti-estrogen therapy is driven by the PI3K/Akt/mTOR pathway and hence the inhibition of this pathway may reverse resistance. This study will evaluate the efficacy of adding everolimus (an inhibitor of mTOR) to anti-estrogen therapy in pts with HR+ metastatic breast cancer (MBC) who have progressed on anti-estrogen therapy.

**Study Objectives:** This multi-center, open-label Phase II trial is designed to determine the efficacy (primary endpoint is PFS), safety and tolerability of everolimus in combination with anti-estrogen therapy in pts with HR+, HER2-negative MBC with disease progression on prior anti-estrogen therapy. An exploratory objective of this study is to evaluate the prognostic value of the VeriStrat assay in this population. VeriStrat testing has been used to predict treatment efficacy in clinical trials of non small cell lung cancer, head and neck squamous carcinoma, and MBC.

**Eligibility:** Pts \(\geq\) 18 years with HR+, HER2-negative breast cancer that is either unresectable, locally recurrent, or metastatic are eligible. Pts must have progressed on anti-estrogen therapy (recurrence while on/within 12 months of treatment for early stage breast cancer, or progressed while on/within 1 month of treatment for advanced/MBC), but anti-estrogen therapy is not required to be the last therapy prior to enrollment. No washout for anti-estrogen therapy is required, and \(\leq\) 1 previous chemotherapy regimen is allowed. Post menopausal or pre-/ peri-menopausal women on tamoxifen are eligible and ovarian function suppression is permitted. Prior treatment with a mTOR inhibitor is not allowed. Additional eligibility requirements include: measurable or evaluable disease, ECOG \(\leq\) 2, adequate bone marrow and organ function and an adequate lipid profile (fasting serum cholesterol \(\leq\) 300 mg/dL or \(\leq\) 7.75 mmol/L and fasting triglyceride \(\leq\) 2.5 x ULN).

**Trial Design:** Everolimus will be administered at a dose of 10 mg PO daily in combination with the FDA prescribed doses of the most recent anti-estrogen therapy on which the pt progressed. Treatment cycles will be 4 weeks, with response evaluations by CT scans every 2 cycles. Pts will be treated until disease progression or unacceptable toxicity occurs. With an alpha=0.5, a sample size of 42 will provide 80% power to detect improvement in median PFS. Blood samples for the VeriStrat assay will be collected at baseline, on Cycle 3 Day 1, at disease progression and at the first follow-up visit post disease progression. Archival tumor tissue samples will be collected for comprehensive genomic profiling. This trial has a total accrual goal of 46 pts.
**Title:** tnAcity: A phase II/III trial of nab-paclitaxel (nab-P) plus either gemcitabine (Gem) or carboplatin (Carbo) vs Gem/Carbo as first-line treatment for patients with triple-negative metastatic breast cancer (TNMBC)

Denise A Yardley, Robert E Coleman, Pierfranco Conte, Joyce O'Shaughnessy, Javier Cortes, Stefan Glück, Adam Brufsky, Jean-Marc A Nabholtz, Li Li, JulieAnn Miller, Debora Barton, Nadia Harbeck and on behalf of the tnAcity Investigators.

**Body:** Background: TNMBC has an aggressive clinical course and poor prognosis. In phase II trials, nab-P–based therapy has demonstrated efficacy and tolerability as first-line therapy, in patients with MBC. The international triple-negative Albumin-bound paclitaxel combination treatment study (tnAcity) will evaluate 2 nab-P regimens (with either Gem or Carbo) and compare the selected regimen with Gem/Carbo as first-line treatment for TNMBC.

**Trial design:** All patients must have pathologically confirmed TNBC (TN defined as < 1% estrogen receptor and progesterone receptor expression by immunohistochemistry (IHC) and 0 - 1+ human epidermal growth factor receptor 2 expression by IHC or confirmed negative by fluorescence in situ hybridization) with measurable metastatic disease. Eligibility criteria include no prior cytotoxic therapy for MBC, prior adjuvant or neoadjuvant anthracycline use unless not indicated by physician or other appropriate regimens were administered, and no history or current evidence of brain metastasis. Prior neoadjuvant or adjuvant chemotherapy must have been completed ≥ 6 months before randomization (≥ 12 months if using taxane-, Gem-, or platinum-containing regimen). Patients will be enrolled internationally in North America, Europe, Latin America, and Australia. In the phase II portion, 240 patients will be randomized to receive nab-P 125 mg/m² plus Gem 1000 mg/m² (arm A), nab-P 125 mg/m² plus Carbo area under the curve (AUC) 2 (arm B), or the control regimen of Gem 1000 mg/m² plus Carbo AUC 2 (arm C), all given intravenously on days 1 and 8 of a 21-day cycle. The phase II portion will identify the nab-P combination to be evaluated in the phase III portion based on efficacy and safety (Table 1). In the phase III portion, 550 patients will receive the selected nab-P regimen (A or B) or Gem/Carbo. The primary endpoint of the phase III portion is progression-free survival (PFS) by independent radiological assessment; secondary endpoints include overall response rate (ORR), overall survival (OS), disease control rate, duration of response, and safety (Table 1). Monotherapy is allowed in the event of hypersensitivity or toxicity to 1 of the treatment components. The trial design provides ≈ 90% power to detect a hazard ratio of 0.70 for PFS with a 2-sided 5% significant level. Current enrollment is 52 patients. Clinical trial NCT01881230.

Title: Phase I/II clinical trial on the combination of carboplatin, eribulin and E7449

Virginia Kaklamani¹, Ruth o’Regan², Kari Wisinski³, Kent Hoskins⁴, James Wade⁵ and William Gradishar¹. ¹Northwestern University, Chicago, IL; ²Emory University, Atlanta, GA; ³University of Wisconsin, Madison, WI; ⁴UIC, Chicago, IL and ⁵CancerCare Specialists of Central Illinois, Dacatur, IL.

Body: The combination of carboplatin and eribulin has been found to be effective in triple negative breast cancer patients. A recently conducted neoadjuvant clinical trial showed a pathologic complete response (pCR) of 45% with four cycle of carboplatin and eribulin. Recent preclinical data from EISAI suggest that there is synergy between carboplatin, eribulin and E7449 (an oral PARP inhibitor) in BRCA deficient and PTEN mutated xenograft models.

Loss of Heterozygosity (LOH) is DNA alterations which develop through double strand DNA breaks. The homologous recombination (HRD) Score is calculated by the number of LOH regions greater 15Mb in length and less than an entire chromosome present in the genome. A high HRD score is present in BRCA deficient tumors and predicts for sensitivity to platinum-based chemotherapy. We propose a phase I/II clinical trial on the combination of carboplatin, eribulin and E7449. As part of the phase I clinical trial HRD will be performed and correlated to response to therapy. In the phase II clinical trial women with BRCA related breast or ovarian cancer, triple negative breast or ovarian cancer with high HRD score or PTEN deficient will be enrolled at a dose level found during the phase I clinical trial. Tissue will be requested to test for PARP inhibition. The primary endpoint of the phase II clinical trial is response rate. A total of 30 patients will be enrolled to the phase II clinical trial.

Title: MERIBEL study: Efficacy of eribulin in first line of taxane-resistant patients with HER2 negative metastatic breast cancer

Vanessa Ortega1, María Martínez2, Antonio Antón3, Isabel Garau4, Lourdes Calvo5, Esperanza Blanco6, Yolanda Fernández7, José Juan Illarramendi8, Mirta García9, Antonio Llombart10, and Javier Cortés10. 1Vall d’Hebron Institute of Oncology, Barcelona, Spain; 2Hospital del Mar, Barcelona, Spain; 3Hospital Universitario Miguel Servet, Zaragoza, Spain; 4Hospital Son Llatzer, Palma de Mallorca, Spain; 5Complejo Hospitalario de A Coruña, A Coruña, Spain; 6Hospital Universitario Infanta Cristina, Badajoz, Spain; 7Hospital Central de Asturias, Oviedo, Spain; 8Hospital General de Navarra, Pamplona, Spain; 9Hospital Insular de las Palmas, Las Palmas de Gran Canaria, Spain and 10Medica Scientia Innovation Research, Barcelona, Spain.

Body: Brief background discussion:
Eribulin is a nontaxane microtubule dynamics inhibitor. It has shown a significant benefit in overall survival in patients with metastatic breast cancer (MBC) that underwent treatments in multiple previous lines (Cortes et al. 2009). However, little is known about the activity of the drug in patients with taxane-resistant early advanced disease. This trial is designed to determine the safety and efficacy of Eribulin as single first line agent in the treatment of patients with HER2(-) MBC deemed resistant to taxanes.

Trial design:
This study is a Phase IIa, multicenter, open-label, single-arm in patients with HER2 (-) metastatic breast cancer clinical trial. The scheme consists in the administration of 1.23 mg/m2 of Eribulin (equivalent to 1.4mg/m2 eribulin mesylate) as single agent the days 1 and 8 of each 21 days of the cycle, until progression of illness, unacceptable toxicity level or investigator’s criteria. The study was approved by the competent authorities and Ethics committees from 14 participating centers in Spain and Portugal.

Eligibility criteria:
The principal inclusion and exclusion criteria were: (1) Patients with MBC that have not received prior chemotherapy for Advanced disease; (2) Previous chemotherapy for early stages (I-IIIB) including taxanes (paclitaxel and/or docetaxel) for at least 4 cycles; (3) Less than 36 months* between the last cycle with taxanes and metastatic relapse; (4) Evaluable disease under RECIST criteria; (5) Absence of HER2 over-expression (IHQ of 0/1 or negative FISH/CISH); (6) Absence of neurotoxicity > G1. (* Amended to 48 months (Llombart et al. ASCO 2013).

Specific aims:
The main objective is to determine the efficacy of Eribulin as single first line agent in the treatment of patients with HER2-negative MBC and taxanes resistant criteria. Secondary objectives are: Estimate the tolerance to the treatment; assess the clinical response of the study treatment by RECIST criteria; correlate hormone receptor status (+/-) with clinical response and tolerability; identify the relationship between presence of visceral disease and response to therapy.

Statistical Methods:
The primary endpoint is time to progression (TTP). Secondary endpoints include the safety of treatment, clinical benefit rate, objective response, progression-free survival and overall survival. A total of 60 patients were predefined for the primary outcome. The sample size is based on a one-arm survival design. We test the null hypothesis that true TTP is 3.7 versus the alternative hypothesis (H1) that TTP is 5.5 months. An interim analysis with 30 patients completed has been planned. The study will be stopped for futility or efficacy if conditional power is less than 20% or more than 80%, respectively. Type I and II error assumed were 5% one-sided and 16%, respectively.

Present accrual:
Currently, 16 women have been recruited for the trial since study start in July 2013. The expected end of accrual will be on March 2015.

A randomized phase II neoadjuvant study of sequential eribulin followed by FAC/FEC-regimen compared to sequential paclitaxel followed by FAC/FEC-regimen in patients with operable breast cancer not overexpressing HER-2

Ricardo H Alvarez1, Nuhad K Ibrahim1, Joe Ensor1, Kimberly Koenig1, Mariana Chavez-MacGregor1, Ana M Gonzalez-Angulo1, Jill Schwartz Gomez1, Aurora G Madrigal1, Savitri Krishnamurthy1, Abigail S Caudle1, Simona F Shaitelman1, Gary J Whitman1, Lee J Murray1, Daniel J Booser1, David Cox2, James M Reuben1 and Vicente Valero1. 1University of Texas MD Anderson Cancer Center, Houston, TX and 2Eisai Inc, Woodcliff Lake, NJ.

Body: Background:
PST is a major component of the multidisciplinary management for locally advanced and operable breast cancer. The sequence of a taxane- followed by anthracycline-based regimen has been our standard of care for almost 20 years. Eribulin is a non-taxane, synthetic analogue of halichondrin B with distinct mechanism of action as microtubule dynamics inhibitor.

Trial Design:
Randomized, single institution, open-label, phase II study. Patients received four cycles of eribulin 1.4 mg/m² on day 1 and 8 every 21 days or 12 weekly doses of paclitaxel 80 mg/m². All patients received 4 cycles of standard doses of FAC/FEC every 21 days.

Eligibility:
Men or women 18 years of age or older with histologically confirmed primary invasive adenocarcinoma of the breast, clinical T2-T3, N0-3, M0, HER2-negative. No prior treatment for invasive carcinoma. Baseline MUGA or echocardiogram scans with LVEF of > 50%. Normal hematology, liver and kidney function laboratory studies.

Research Hypothesis:
Eribulin followed by FAC/FEC-regimen would demonstrate higher pathological complete response (pCR) rate relative to paclitaxel followed by FAC/FEC-regimen as PST for woman with operable breast cancer.

Specific Aims:
Primary objective: To estimate the pCR rate of eribulin followed by FAC/FEC-regimen versus paclitaxel followed by FAC/FEC-regimen. Secondary objectives: To evaluate the safety and rate of breast conservation surgery of eribulin followed by FAC/FEC-regimen.

Exploratory analysis: To explore Hot Spot Mutation Analysis (HSMA) and Molecular Inversion Probes (MIP) arrays can differentially predict pCR to eribulin followed by FAC/FEC-regimen versus paclitaxel followed by FAC/FEC-regimen. To determine the effect of eribulin on the circulating tumor cells (CTCs) number and epithelial and /or EMT gene expression in peripheral blood.

Statistical Methods:
The efficacy endpoint is the pCR rate. Patients are electronically randomized in a 1:1 ratio into two groups. Group A will receive eribulin followed by FAC/FEC-regimen and group B will receive paclitaxel followed by FAC/FEC-regimen. A binomial superiority two-sample test for population proportions will be used to compare the pCR rates of the two groups. An interim futility analysis is planned for this two-stage trial after the endpoint has been evaluated for the first 46 patients. If the test statistic at the end of the first stage is less than -0.876, the trials will stop for futility; otherwise, the trial will continue until 152 patients are accrued. A test statistic greater than 1.272 at the end of the second stage implies that the pCR rate for group A is significantly better. These calculations assume: an alpha error of 0.10, 80% power, a treatment arm assignment fraction of 50%, and an alpha spending function based on the O’Brien-Fleming boundary.

Present Accrual and Target Accrual:
A total of 48 patients were accrued. Target accrual is 152 patients.

Title: Metronomic eribulin in metastatic breast cancer

Pavani Chalasani², Livingston B Robert³, Thomas A Rado³, Vijayakrishna K Gadi¹, Thomas D Kummet⁴, Jennifer M Specht¹, Alison Stopeck² and Hannah M Linden¹. ¹University of Washington, Seattle Cancer Care Alliance, Seattle, WA; ²University of Arizona Cancer Center, Tucson, AZ; ³Columbia Basin Hematology and Oncology, Kennewick, WA and ⁴Olympic Medical Cancer Center, Sequim, WA.

Body: Introduction: Breast cancer is a common and curable malignancy. In the setting of late or early recurrence, improvement in therapy is indicated as overall survival (OS) has changed little over the past few decades. Eribulin mesylate is a non-taxane microtubule dynamics inhibitor FDA approved in salvage metastatic breast cancer (MBC) treatment based on improvements in OS. Eribulin mesylate is a synthetic analogue of halichondrin B, a product isolated from the marine sponge *Halichondria okadai*. Anti-tubulin therapy is an established cornerstone of chemotherapeutics for MBC. Work at our center and others has shown a favorable therapeutic index for weekly metronomic vinorelbine. The history of other effective and tolerable agents, including paclitaxel, capecitabine, and vinorelbine, suggests that a low dose metronomic schedule of eribulin could be effective, well tolerated and result in longer time to progression (TTP), and higher quality of life during therapy. In phase I studies, Eribulin showed activity at doses well below the maximally tolerated 1.4mg/m² given 2/3 weeks, suggesting a lower metronomic schedule would not compromise efficacy. A lower dose metronomic schedule will allow responding patients to remain on treatment, resulting in longer TTP and greater use of the drug in practice.

Study Design: This is an open-label, multi-center, phase II study of eribulin for patients with MBC. HER2 positive patients may enroll with concomitant use of trastuzumab. Patients will receive eribulin 0.9 mg/m² administered intravenously over 2 to 5 minutes on Days 1, 8 and 15 of a 28-day cycle. Treatment will be continued until disease progression, unacceptable toxicity or withdrawal of patient consent.

Eligibility Criteria: Patients with MBC whose disease has progressed following 1-6 prior regimens with prior exposure to a taxane, ECOG PS of 0 – 2, measurable disease per RECIST 1.1, normal marrow and organ function. Patients with known CNS metastases must have stable disease off steroids after treatment with surgery or radiation. Exclusion criteria: mild hepatic or renal impairment, grade > 2 peripheral neuropathy, significant cardiovascular impairment or other severe or uncontrolled medical disease or psychiatric or neurologic disorder.

Specific Aims: The primary aim is to increase progression free survival (PFS). We hypothesize that metronomic dosing of eribulin will result in PFS of 4-6 months.
Secondary aims include decreasing the frequency of alopecia to less than 50%, grade 3 or 4 neutropenia to less than 30% and sensory neuropathy (all grades) to less than 25% of subjects enrolled.
An exploratory aim is to assess the role of circulating endothelial cell precursors (CEPs) and apoptotic circulating endothelial cells in predicting early response to treatment.

Statistical Methods: PFS will be measured as the time from study enrollment until the earliest date of disease progression or death. The sample size of n=60 has 99% power for the lower bound of the confidence interval to be greater than 2.2 months (the median PFS in the physician’s discretion arm of the EMBRACE trial), assuming that the true median PFS is 4 months, comparable to or an incremental improvement over the median PFS for the eribulin arm of the EMBRACE trial (3.7 months). Currently 12 of 60 expected enrollments have occurred.
Title: Phase II single arm study of liposomal doxorubicin (D), bevacizumab (A), and temsirolimus (T) for treatment of triple negative early breast cancer refractory to standard neoadjuvant chemotherapy

University of Texas MD Anderson Cancer Center, Houston, TX and University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Background: Historically, triple negative breast cancers (TNBCs) were categorized into an ill-defined group that lacked estrogen receptors, progesterone receptors, and overexpression of human epidermal growth factor receptor 2. When TNBCs are treated with standard neoadjuvant chemotherapy (NAC), a pathologic complete response (pCR) is achieved in only 30-50% of the time. In an effort to improve outcomes for chemotherapy - refractory disease, emerging subtypes of TNBC have been identified through advances in molecular profiling leading to the discovery of distinct molecular aberrations which may be targeted. For example, mesenchymal-like TNBCs are a subset with aberrations that activate the PI3K/AKT/mTOR axis. Similar to mesenchymal-like, metaplastic breast cancers are commonly triple negative, refractory to standard therapy, and also harbor a high rate of molecular aberrations that lead to activation of the PI3K pathway. As such, metaplastic tumors may act as a morphologically identified ‘surrogate of response’ to evaluate the activity of targeted therapy regimens in mesenchymal-like TNBC. Based upon favorable results noted in a phase I trial of liposomal doxorubicin, bevacizumab, and the mTOR inhibitor temsirolimus (DAT) in metastatic metaplastic tumors, we will conduct this single arm phase II trial with neoadjuvant DAT for chemotherapy-refractory mesenchymal-like TNBC.

Trial Design: At our institution, women with TNBC who are receiving NAC will be enrolled onto a triaging protocol, where they will be randomized in a 2:1 fashion to be evaluated by a microarray-based predictive signature to determine chemotherapy sensitivity and categorized as chemotherapy-sensitive (CS) or chemotherapy-insensitive (CI). Subsequently, patients will be treated with standard anthracycline-based chemotherapy (AC or FAC) for 4 cycles. Patients with CI tumors with <80% decrease in tumor size and those with CS tumors with <10% decrease in tumor size will be deemed non-responders. Mesenchymal-like non-responders will be recommended for this single arm phase II study of DAT. Eligible patients will receive D at a dose of 30mg/m2 IV on day 1, A at 15 mg/kg IV on Day 1, and T at 25mg IV on Days 1, 8, and 15 for 4 cycles.

Eligibility Criteria: Female; > 18 years of age; newly diagnosed stage I-III triple negative breast cancer; refractory to standard NAC; LVEF > 50% by Echocardiogram or MUGA; ECOG PS 0-1

Statistical Methods: The primary endpoint is pCR following therapy with DAT. Secondary objectives will include recurrence-free survival and overall survival. Using a Simon optimal two-stage design with alpha = beta = 10%, and then setting the threshold for an acceptable pCR rate at 20%, we would enroll 12 patients into the first stage. If we see 0 patients with pCR, we would stop the study after the first stage. If we see at least one patient with a pCR we will continue to enroll 25 more patients for a total of 37 patients. We would declare the treatment worthy of further study if we see at least 4 patients with pCR out of the 37 patients. This design has a 54% probability of early termination after the first stage if the true pCR probability is 5%.

Target Accrual: 37.
A phase II study of S-1 (14 days' administration followed by 7 days' rest) for metastatic breast cancer

Akira Hirano¹, Akinori Hattori¹, Kaoru Ogura¹, Hiroaki Inoue¹, Fumie Okubo¹, Mari Kamimura¹, Shiho Sakaguchi¹, Jun Kinoshita¹, Reiko Miyamoto², Norie Jibiki², Yoshihiko Naritaka¹ and Tadao Shimizu¹.

1Tokyo Women's Medical University, Medical Center East, Tokyo, Japan and 2Tokyo Women's Medical University, Yachiyo Medical Center, Yachiyo, Japan.

Body: Background
S-1, an orally administered fluorinated pyrimidine (FP), improves overall survival in the adjuvant setting of gastric and pancreatic cancer. It is also effective for metastatic breast cancer (Yamamoto et al. Anticancer Res 30:3827-32, 2010). Although S-1 is usually administered for 28 days followed by 14 days' rest, severe adverse events are often observed by Day 15. By altering the schedule into 14 days' administration followed by 7 days' rest, discontinuation of treatment can often be avoided in daily practice. This schedule maintains the same dose intensity. Equally, an anti-tumor effect and fewer adverse events are observed in 14 days' administration followed by 7 days' rest than in 28 days' administration followed by 14 days' rest for the treatment of squamous cell carcinoma of the head and neck (Tsukuda et al. Br J Cancer 93:884-889, 2005).

In order to reduce the occurrence and severity of adverse events of S-1, we paid attention to dose reduction according to the renal function of patients. S-1 is comprised of tegafur, 5-chloro-2, 4-dihydroxy-pyridine(CDHP) and potassium oxonate. CDHP enhances the serum concentration of 5-FU by inhibiting dihydropyrimidine dehydrogenase (DPD), and it is excreted by the kidneys. Therefore, an accumulation of DPD in patients with renal dysfunction escalates the serum concentration of 5-FU and induces more severe adverse events. Thus, the dosage of S-1 should be reduced according to renal function.

Trial design
This is a phase II trial to evaluate the efficacy and toxicity of S-1 (14 days' administration followed by 7 days' rest) for metastatic breast cancer. S-1 is administered orally twice daily at a dose of 40-60 mg depending on the BSA and creatinine-clearance from Days 1 to 14, which is followed by 7 days' rest. This treatment is repeated until disease progression.

Eligibility criteria
Patients with histologically confirmed breast cancer, and recurrent and/or metastatic disease are included. Patients with HER2-positive (IHC:3+ or FISH+) tumor are excluded. Patients within 2 lines of previous chemotherapy for metastatic disease are allowed. Eligible patients are aged between 20 years and 80 years with a performance status of 0 to 2 and adequate organ function.

Specific aims
The primary endpoint is the response rate, and the secondary endpoints are disease control rate, progression-free survival, time to failure, toxicities and feasibility.

Statistical methods
The sample size was calculated using the Simon method, with a type I error of 5% and a study power of 90%. The unpromising response rate was 15% and the promising rate was 42%. The required number of patients was estimated to be 23.

Target accrual
Accrual of 25 patients was planned to produce a minimum of 23 evaluable patients. Patient accrual started in June 2014.
Title: A Phase IIb study of ANG1005, a novel, brain-penetrant taxane derivative, in HER2+ breast cancer patients with brain metastases

Betty Lawrence¹, Veronica Burdusel¹, Dimitri Fitsialos², Sana Ghani¹, Vihra Iordanova¹ and Jean-Paul Castaigne¹. ¹Angiochem Inc, Montreal, QC, Canada and ²Integrated Therapeutic Solutions Inc, Toronto, ON, Canada.

Body: Background:
Brain metastases are diagnosed in 30-55% of women with HER2+ breast cancer and represent a significant cause of morbidity and mortality in this patient population. While systemic disease can be controlled with HER2 receptor-directed therapy, treatment options for the CNS disease are limited due to the inability of most anti-cancer agents to cross the blood brain barrier (BBB). ANG1005 is a novel, targeted taxane derivative, consisting of 3 paclitaxel molecules covalently linked to a 19 amino-acid peptide that targets the low-density lipoprotein receptor-related protein 1 (LRP-1) receptor, which is highly expressed on the surface of the BBB and on various neoplastic cells. Using the LRP-1 receptor-mediated pathway, ANG1005 can cross the BBB and enter the tumor cells, where paclitaxel is cleaved off to exert its anti-tumor activity.

Trial Design:
This is an open-label, multi-center Phase II study to evaluate the efficacy, safety and tolerability of ANG1005 in patients with HER2+ breast cancer and progressive/recurrent brain metastases following whole brain radiotherapy (WBRT). Approximately 40 patients will be enrolled in the study and will receive ANG1005 at a starting dose of 600 mg/m² by intravenous infusion every 3 weeks. MRI and CT scans will be performed at screening and after every 2 cycles (i.e., every 6 ± 2 weeks) during treatment according to CNS RECIST 1.1 and RECIST 1.1 for intracranial and extracranial tumor evaluation, respectively. The maximum treatment duration is 1 year.

Eligibility Criteria:
Eligible patients are adults (≥18 years old) with HER2+ breast cancer with recurrent/progressive brain metastases who have received prior WBRT. Patients must have at least one radiologically-confirmed metastatic brain lesion, measurable according to CNS RECIST 1.1. Patients must be neurologically stable and have adequate blood counts, organ and bone marrow function with a KPS score ≥80. Patients with leptomeningeal disease are excluded, as are patients who have been previously treated with ANG1005 or have known allergy to paclitaxel or its components.

Specific aims:
The primary endpoint is to evaluate the intracranial objective response rate (iORR). Additional endpoints include: median intracranial progression free survival (PFS), overall PFS at 3, 6 and 12 months, 6-month overall survival rate, intracranial ORR by 2-D modified RANO criteria, overall ORR, extracranial ORR and duration of response, plasma pharmacokinetic profile, and safety and tolerability.

Statistical Methods:
The primary objective is to determine the efficacy of ANG1005 as measured by iORR. Sample size calculation is based on Exact test statistical method with testing null hypothesis: iORR equals historical control iORR versus alternative hypothesis H1: iORR > historical control iORR with one sided alpha=0.05. A sample size of 40 has 92% power to reject iORR being 5%, assumed the study has an iORR of 20%.

Study Accrual:
Target accrual is 40 patients. The study is open for recruitment and currently no patients have been enrolled.

Contact Information:
For more information on this trial, please contact Betty Lawrence at Angiochem Inc. (blawrence@angiochem.com). Clinical trial information: NCT02048059.
Title: SGN-LIV1A: A phase 1 trial evaluating a novel antibody-drug conjugate in patients with LIV-1-positive breast cancer

Andres Forero\textsuperscript{1}, Howard Burris III\textsuperscript{2}, Patricia LoRusso\textsuperscript{3}, Jennifer Specht\textsuperscript{4}, Kathy Miller\textsuperscript{5}, Monica Mita\textsuperscript{6}, Minetta C Liu\textsuperscript{7}, Shanu Modi\textsuperscript{8}, Lajos Pusztai\textsuperscript{9}, Django Sussman\textsuperscript{10} and Ana Kostic\textsuperscript{10}. \textsuperscript{1}University of Alabama, Birmingham, AL; \textsuperscript{2}Sarah Cannon Research Institute, Nashville, TN; \textsuperscript{3}Karmanos Cancer Institute, Detroit, MI; \textsuperscript{4}Seattle Cancer Care Alliance, University of Washington, Seattle, WA; \textsuperscript{5}Indiana University Simon Cancer Center, Indianapolis, IN; \textsuperscript{6}Cedars-Sinai Medical Center, Los Angeles, CA; \textsuperscript{7}Mayo Clinic, Rochester, MN; \textsuperscript{8}Memorial Sloan Kettering Cancer Center, New York, NY; \textsuperscript{9}Yale University School of Medicine, New Haven, CT and \textsuperscript{10}Seattle Genetics, Inc, Bothell, WA.

Body: Background

First identified as an estrogen-inducible gene in a breast cancer cell line, LIV-1 is a multispan transmembrane protein of the solute-carrier family 39 with putative zinc transporter and metalloproteinase activity. As a downstream target of STAT3, it promotes the epithelial-to-mesenchymal transition that is important in the malignant progression to metastasis. LIV-1 is expressed in a number of cancers with the highest prevalence and level of expression in breast, prostate, and melanoma. Additionally, LIV-1 has been linked with malignant progression to metastasis and associated with lymph node involvement in breast cancer. Normal tissue expression is predominantly limited to hormonally regulated tissues, including breast and prostate. In metastatic breast cancer tissue samples, the current validated immunohistochemistry assay for LIV-1 has detected moderate to high expression in 82% of samples tested, with 88% positivity in hormone receptor-positive tumors and 73% in triple-negative tumors.

SGN-LIV1A is an antibody-drug conjugate (ADC) composed of a humanized anti-LIV-1 monoclonal antibody conjugated to the microtubule-disrupting agent monomethyl auristatin E (MMAE) via a protease-cleavable linker. In vitro, SGN-LIV1A shows target-specific internalization and cytotoxic activity against LIV-1-positive neoplastic cell lines. Significant dose-dependent tumor regression was demonstrated in mouse xenograft models.

Methods

The primary objective of this first-in-human phase 1, open label, multicenter study is to evaluate the safety and tolerability, and to identify the maximum tolerated dose of SGN-LIV1A using a 3+3 dose-escalation study design. Pharmacokinetics, immunogenicity, and antitumor activity will also be evaluated (ClinicalTrials.gov #NCT01969643). Enrollment to this US-based trial began in late 2013. Eligible patients are adult females who have hormone receptor-positive/HER2-negative or triple-negative metastatic breast cancer. Tumor tissue must be positive for expression of LIV-1 per central assessment. Patients must have received at least 2 prior cytotoxic regimens in the metastatic setting and have measurable disease per RECIST v1.1. Pre-existing neuropathy ≥ Grade 2 is not permitted.

SGN-LIV1A is administered intravenously every 3 weeks at protocol-defined doses starting at 0.5 mg/kg. Patients who achieve an objective response or stable disease per RECIST v1.1 are eligible to continue treatment until disease progression. At the completion of dose escalation, expansion cohorts may be opened to enroll patients with specific breast cancer subtypes to further define safety and antitumor activity. Tumor biopsies are being obtained at baseline and after one cycle of treatment to evaluate the role of LIV-1 expression, target saturation, and other tumor-specific measurements in the antitumor activity of SGN-LIV1A.
Title: A prospective study of glycoprotein 88 GP-88 blood test in healthy women with Gail model risk <=1.66 undergoing screening for breast cancer (BC) with mammography (MM)

Katherine HR Tkaczuk¹, Cristina Campassi¹, Susan Kesmodel¹, Emily Bellavance¹, John Olson¹, Elizabeth Nichols¹, Steven J Feigenberg¹, Binbin Yue², David Hicks² and Ginette Serrero². ¹University of Maryland Greenebaum Cancer Center, Baltimore, MD and ²A & G Pharmaceutical, Columbia, MD.

Body: Background: In the US, the majority of BC is diagnosed by screening XRAY mammography (MM) but up to ~20% of BC are undetected by MM. The development of reliable, blood-based BC screening test to increase the sensitivity and specificity of currently existing BC screening methods such as MM.

Rationale: GP88 is expressed & secreted by BC cells & is not expressed by normal mammary epithelial cells. Two retrospective randomized multi-site trials (one training study & one validating study with about 300 cases each) have demonstrated that elevated GP88 expression in ER+ IDC was statistically correlated with a 4-fold increase in the risk of 5-yr disease recurrence. Multivariate analysis showed that GP88 as a risk predictor was independent from PR expression, tumor size, grade, lymph node status & disease stage. The quantitative GP88 EIA developed to determine the amount of GP88 in biological fluids was developed at A&G. The assay is highly specific for GP88 & both sensitive & linear over a wide dynamic range, i.e. detection of GP88 concentrations from 0.1 to 20ng/ml. A baseline (28.4 ± 5 ng/ml) was established for healthy volunteers (HV). In BC pts a statistically significant increase of serum GP88 was seen for early stage pts (40.7 ± 16 ng/ml; p=0.007). Additionally, a stratification of pts according to their clinical outcomes shows that pts having no evidence of disease (NED) have serum GP88 levels within the range of HV. These data suggest that pts with breast tumors express & secrete high levels of GP88.

Objectives: 1. To determine prospectively GP-88 blood levels in HV at average risk of developing BC who are undergoing screening MM & in women with biopsy-confirmed BC. 2. To establish the statistical distribution of GP88 serum levels in these women by baseline BIRAD classification (1-6). 3. To determine if baseline GP88 level is predictive of change in BIRADS classification from baseline to 12-mos follow-up. 4. To determine if baseline GP88 level is predictive of the appearance of BC at 12 mos follow-up in HV who were cancer-free at baseline.

Inclusion Criteria: Female, aged >=40 yrs old, presenting to UM Breast Center for screening MM or for diagnostic MM or diagnostic workup and/or biopsy due to BIRADS 0 MM at an outside facility <= to 12 wks; Gail model assessment of risk of developing BC<=1.66.

Study procedures: Serum levels of GP88 in subjects with average BC risk factors will be measured prospectively at baseline; 3-6 mos & 6-12 mos. & correlated with BIRADS reading of the screening MM, BIRADS 1 or 2 (benign), BIRADS 3 (short term MM follow-up) & BIRADS 4 or 5 (suspicious and tissue diagnosis needed immediately). GP88 blood level will be correlated with pathologic results of breast biopsies performed on subjects with suspicious BIRADS (4 & 5) MM & final pathologically confirmed diagnosis of BC as BIRADS 6.

Statistical Considerations The total number of pts will be 725 & screened up to 1400 subjects. Study is UM IRB approved & just started accruing. Funding is provided by Maryland Industry Partnership Grant (MIPS)& Avon Grant No. 02-2013-018. Contact: Ntait@umm.edu.
Title: Testing BRCA 1/2 mutation using next generation sequencing (BRCANGS)

Hyung Seok Park¹, Seo Jin Park¹, Sanghwa Kim¹, Jegyu Ryu¹, Jee Ye Kim¹, Seho Park¹, Seung Il Kim¹, Joo Hyuk Sohn¹ and Jong Rak Choi¹. ¹Yonsei University College of Medicine, Seoul, Seodaemoongu, Korea.

Body: Testing BRCA 1/2 mutation is important for patients with breast cancer, and Sanger sequencing is a standard method to identify BRCA 1/2 mutation. Next generation sequencing (NGS) is a high-throughput parallel sequencing that can provide genetic information with high accuracy. NGS is a faster and cost-effective method to detect gene mutations compared to Sanger sequencing. This study is a prospective non-randomized observational study which evaluates the clinical role of NGS testing for BRCA 1/2 compared to Sanger sequencing. Eligibility criteria are women aged 19 to 80 years, patients with breast or ovarian cancer history in 2nd degree family members, male breast cancer, bilateral breast cancer, patient with breast cancer under 40 year of age, simultaneous breast and ovarian cancer, patients with epithelial ovarian cancer, and breast cancer with other simultaneous extramammary malignancy. Primary endpoint of the study is the overall accuracy of NGS compared to Sanger sequencing. Secondary endpoints are sensitivity, specificity, false negative, and false positive rates of NGS compared to Sanger method. Target accrual of the pilot study is 12 patients, and further extension of patients accrual is scheduled after the analysis of the pilot study. This study is approved by institutional review board of Severance Hospital. The study is conducted and planned by Prof. HS Park, Yonsei University College of Medicine, Seoul, Korea and supported by Korea Breast Cancer Foundation. ClinicalTrials.gov identifier is NCT02151747.

Title: Brain metastases in breast cancer network Germany (BMBC, GBG 79): Multicentric, retro- and prospective collection of patient data and biomaterial from breast cancer patients with brain metastases

Isabell Witzel¹, Elena Laakmann¹, Tanja Fehm², Volker Möbus³, Gunter von Minckwitz⁴, Julia Kaiser⁴, Sibylle Loibl⁴ and Volkmar Müller¹. ¹University Medical Center Hamburg-Eppendorf, Hamburg, Germany; ²Translational Research Board of the Arbeitsgemeinschaft für Gynäkologische Onkologie (AGO-Trafo), Germany; ³Breast Study Group of the Arbeitsgemeinschaft für Gynäkologische Onkologie (AGO-B), Germany and ⁴German Breast Group, Neu-Isenburg, Hessen, Germany.

Body: Background: The incidence of brain metastases in breast cancer patients is rising and has become a major clinical challenge in the last years. So far, limited therapeutic options and insights into the biology of brain metastases exist. Most reports include patients with brain metastases from different tumor entities and few studies so far analyzed exclusively patient data or tumor samples from breast cancer patients. In this context, an open, multicenter registry and biobank should be helpful for analysis of a large number of breast cancer patients with brain metastases. Therefore, we initiated the Brain Metastases in Breast Cancer Network Germany (BMBC; GBG79).

Trial design and eligibility criteria: Patients with brain metastases from breast cancer are eligible. Registration of patient data is allowed retrospectively and prospectively. To enable an easy access, an internet-based database was chosen ("MedCodes" by the German Breast Group).

Specific aims: Documented data cover incidence, symptoms, number and localization of brain metastases, histopathology, imaging methods, outcome, therapy, and quality of life measurement. Tissue of brain metastases and primary tumors will be collected for translational research projects. Planned analyses include treatment patterns in Germany, patient outcome, as well as validation of prognostic scoring systems in a multicenter setting and in the context of new targeted therapies. Translational research projects investigate the impact of glycosylation, resistance mechanisms against HER2-targeted therapies, role of the blood brain barrier, evaluation of markers of radioresistance and specific genomic alterations associated with brain tropism of breast cancer cells. The registry and biobank should be also open for cooperation with other groups.

Present accrual and target accrual: The accrual target is app. 1000 patients in the database and app. 400 tissues of brain metastases from German centers. The study was opened for documentation in April 2014 with more than 50 participating centers as of June 2014.
A phase 2 randomized, double-blind, placebo-controlled trial of hormone therapy ± radium-223 dichloride in HER2-negative hormone receptor–positive breast cancer patients with bone metastases

Robert E Coleman¹, Liping Huang², Oana Petrenciuc² and Paola Zaccarin³. ¹Weston Park Hospital, Sheffield, United Kingdom; ²Bayer HealthCare, Whippany, NJ and ³Bayer S.p.A., Milan, Italy.

Background: Bone metastases (mets) are frequent in patients (pts) with metastatic breast cancer (MBC). Radium-223 dichloride (Ra-223) is a first-in-class alpha-emitter that selectively targets bone mets, which in a phase 2a pilot study of advanced breast cancer pts with bone-dominant disease (n=23), reduced baseline bone biomarker levels with favorable safety (Coleman et al. Breast Cancer Res Treat 2014). This study will evaluate efficacy and safety of Ra-223 versus placebo (pbo) in HER2-negative hormone receptor–positive breast cancer pts with bone mets receiving single-agent hormone therapy.

Trial Design: Eligible pts will be randomized 1:1 to Ra-223 50 kBq/kg IV or matching pbo every 4 weeks for 6 cycles. Additionally, all pts will receive concurrent single-agent hormone therapy and best supportive care for the entire study. Randomization will be stratified by geographic region, previous lines of hormone therapy for MBC, and number of prior skeletal events. Pts will be assessed at each visit for efficacy and safety, and followed until occurrence of symptomatic skeletal event (SSE), radiologic progression, death, or withdrawal.

Main Eligibility Criteria: Eligible pts are pre- or postmenopausal women with histologically or cytologically confirmed estrogen receptor–positive, HER2-negative, bone-dominant MBC with ≥2 radiologically confirmed bone mets and ≥1 or 2 prior skeletal events (ie, external beam radiotherapy for bone pain, pathologic bone fracture, spinal cord compression, orthopedic surgery). Pts must have had ≥1 line of hormone therapy for MBC; be taking bisphosphonates or denosumab for ≥3 months prior to study entry; be eligible for endocrine treatment (one of selective estrogen receptor modulators [SERMs], nonsteroidal aromatase inhibitors [NSAIs], steroidal AIs, or estrogen receptor downregulators); and have radiologically evaluable disease using RECIST 1.1, asymptomatic or mildly symptomatic disease on Brief Pain Inventory, ECOG score 0-1, and adequate hematologic, renal, and liver function. Exclusion criteria include history or presence of visceral mets, history or presence of brain mets or leptomeningeal disease, prior or current need for chemotherapy for metastatic disease, and untreated spinal cord compression.

Endpoints: The primary endpoint is SSE-free survival. Secondary endpoints are radiologic progression-free survival (rPFS), overall survival, time to opiate use for cancer pain, time to pain progression, time to cytotoxic chemotherapy, and acute and long-term safety. Exploratory endpoints include time to first on-study SSE, bone biomarker assessments, bone-specific rPFS, resource utilization, and time to visceral mets onset.

Statistical Methods: Target enrollment is 227 pts. Time-to-event variables will be analyzed using a log-rank test, accounting for trial stratification factors. Kaplan-Meier estimates and survival curves will be presented for each treatment group. Safety analyses will be descriptive.

First patient first visit expected in Sept 2014.
Title: A two-cohort, phase II, cardiac safety study of pertuzumab, trastuzumab, and neoadjuvant anthracycline-based chemotherapy in patients with HER2-positive, locally advanced, inflammatory, or early breast cancer

Sandra M Swain¹, Michael S Ewer², Hannah Douthwaite³, Tania Szado⁴, Maeve Waldron-Lynch³ and Chau Dang⁵. ¹MedStar Washington Hospital Center, Washington, DC; ²University of Texas MD Anderson Cancer Center, Houston, TX; ³Roche Products Limited, Welwyn, United Kingdom; ⁴Genentech, San Francisco, CA and ⁵Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Background: In HER2-positive early breast cancer (BC), neoadjuvant pertuzumab (P) + trastuzumab (T) + docetaxel (D) significantly increased pathologic complete response (pCR) rates compared with T+D (Gianni L, et al. Lancet Oncol 2012); high pCR rates were also seen with P+T in combination with anthracycline- and non-anthracycline-based regimens (Schneeweiss A, et al. Ann Oncol 2013). Neoadjuvant P+T + chemotherapy was well tolerated, with little increased toxicity associated with the addition of P. Although there was a higher rate of cardiac adverse events (AEs), left ventricular systolic dysfunction (LVSD), and left ventricular ejection fraction (LVEF) declines in P+T-containing arms compared with arms without P, these events were generally asymptomatic, reversible, and patients (pts) recovered with no sequelae. No data are available for neoadjuvant P-based regimens that include paclitaxel (Ptx) and dose-dense doxorubicin plus cyclophosphamide (ddAC), despite these being widely used in (neo)adjuvant BC therapy. This study will evaluate the cardiac safety of two anthracycline-based neoadjuvant regimens in combination with P+T. Following surgery, all pts will receive adjuvant P+T.

Trial design: In this non-randomized, open-label, phase II study, two parallel cohorts of pts receive different P-based neoadjuvant treatment regimens. In Cohort A, pts receive four 2-weekly cycles of ddAC, followed by 12 doses of weekly Ptx, plus four 3-weekly (q3w) cycles of P+T from the start of Ptx. In Cohort B, pts receive four q3w cycles of 5-fluorouracil, epirubicin, and cyclophosphamide, followed by four q3w cycles of D, plus four q3w cycles of P+T from the start of D. Following surgery, both cohorts receive 13 cycles of P+T.

Eligibility: Pts with HER2-positive, locally advanced, inflammatory, or early BC (size >2 cm or >5 mm and node-positive) are eligible if they have a baseline LVEF ≥55% and an ECOG performance status ≤1. Among the exclusion criteria are prior incisional biopsy or excision of the primary tumor, prior systemic or radiation therapy for cancer, and prior chemopreventive agents. Pts are also excluded if they have poorly controlled hypertension, angina requiring medication, a history of congestive heart failure, serious or uncontrolled cardiac arrhythmia requiring treatment, or myocardial infarction within 6 months prior to enrollment.

Aims: The primary objective is cardiac safety during the neoadjuvant period, assessed by incidence of symptomatic LVSD and LVEF changes. Secondary objectives include cardiac safety in the adjuvant and post-treatment periods, incidence of all AEs, pCR rate, event-free survival, invasive disease-free survival, and overall survival.

Statistical methods: No statistical hypothesis testing will be performed. Safety and efficacy results will be summarized descriptively. A sample size of 200 pts per cohort is expected to provide sufficient data to evaluate the cardiac safety of each regimen with acceptable precision (exact Clopper-Pearson 95% CIs) around the expected rates.

Accrual: The first patient in is planned for August 2014.
Title: A Phase 3 randomized, double-blind trial comparing PF-05280014 + docetaxel and carboplatin vs. trastuzumab + docetaxel and carboplatin for neoadjuvant treatment of operable HER2+ breast cancer

Ira Jacobs1, Jennifer Coiro1, Fiona Hilton2, John Orazem2, Richat Abbas3 and Charles Zacharchuk4. 1Oncology Biosimilars, Pfizer, New York, NY; 2Clinical Statistics, Pfizer, New York, NY; 3GEPB, Pfizer, Collegeville, PA and 4Pfizer, Cambridge, MA.

Body: Background: PF-05280014 is being developed as a potential biosimilar to trastuzumab. PF-05280014 demonstrated similarity to trastuzumab in nonclinical evaluations. In a Phase I trial in healthy subjects, pharmacokinetic (PK) characteristics and safety profile of PF-05280014 were similar to those of trastuzumab. The goal of this Phase 3 trial is to demonstrate that the efficacy and safety of PF-05280014 + docetaxel and carboplatin are similar to those of trastuzumab sourced from the EU (trastuzumab-EU) + docetaxel and carboplatin in the neoadjuvant treatment of women with HER2-positive operable breast cancer.

Trial design: In this randomized, double-blind trial, subjects will be randomized (1:1) with stratification by primary tumor size (<5 cm or ≥5 cm), estrogen receptor (ER) status, and progesterone receptor (PR) status to PF-05280014 + docetaxel and carboplatin or trastuzumab-EU + docetaxel and carboplatin. PF-05280014 or trastuzumab (8 mg/kg in Cycle 1; 6 mg/kg thereafter over 90 min) will be administered followed by docetaxel (75 mg/m²) and carboplatin (target area under the curve [AUC]: 6 mg/mL/min; 30- to 60-minute infusion) every 3 weeks for 6 treatment cycles. The primary objective is to compare the percentages of patients with Cycle 5 Ctrough (trastuzumab serum trough concentration) >20 µg/mL in the neoadjuvant setting. Secondary objectives include measures of tumor control, safety, immunogenicity, PK, and to explore the relationship between drug exposure and pathologic complete response (pCR).

Eligibility criteria: Female subjects with known ER and PR status ≥18 years with confirmed HER2 overexpressing breast cancer and a plan for definitive surgical resection and neoadjuvant chemotherapy, Eastern Cooperative Oncology Group status 0 or 1, normal left ventricular ejection fraction and normal laboratory values are eligible. Key exclusion criteria are bilateral or inflammatory breast cancer; prior treatment, including chemotherapy, endocrine therapy, biologic therapy, radiation or surgery (except diagnostic biopsy); other concomitant active malignancy or history of malignancy in the past 5 years or presence of known distant metastases. All subjects must provide informed consent.

Specific aims: The goal of this Phase 3 trial is to demonstrate that PF-05280014 in combination with docetaxel and carboplatin has similarity in PK (trough level) and comparable efficacy and safety versus trastuzumab-EU + docetaxel and carboplatin in subjects with operable HER2-positive breast cancer in the neoadjuvant setting.

Statistical methods: This study tests whether percentage of subjects with steady state (Cycle 5) Ctrough >20 µg/mL of PF-05280014 is similar to that of trastuzumab-EU, using a noninferiority margin of -12.5% tested with α=0.025 (one-sided). Assuming the percentages of subjects reaching steady state is 95% with trastuzumab-EU and 93% with PF-05280014, 188 subjects (94/arm) will be needed to achieve 85% power.

Target accrual: 220 subjects.
Title: An open-label, multicentre, phase IIIb study with intravenous administration of pertuzumab, subcutaneous trastuzumab, and a taxane in patients with HER2-positive metastatic breast cancer (SAPPHIRE)

Natasha Woodward\(^1\), Richard H De Boer\(^2\), Andrew Redfern\(^3\), Vita Von Neumann-Cosel\(^4\), Ronelle M Heath\(^5\) and Jane Beith\(^6\).\(^1\) Mater Hospital Cancer Services, Brisbane, Queensland, Australia; \(^2\) Royal Melbourne Hospital, Parkville, VIC, Australia; \(^3\) Royal Perth Hospital, Perth, WA, Australia; \(^4\) Roche Products, Pty. Limited, Dee Why, NSW, Australia; \(^5\) Novotech, (Australia) Pty. Limited, Pyrmont, NSW, Australia and \(^6\) Chris O'Brien Lifehouse, Camperdown, NSW, Australia.

Body: Background: The primary goals of treatment for patients (pts) with metastatic breast cancer (mBC) are maximising survival and preserving the quality of life. Intravenous (IV) trastuzumab has proven clinical benefits in pts with human epidermal growth factor receptor 2 (HER2)-positive mBC. Pertuzumab also targets HER2 through an independent epitope to that of trastuzumab. Addition of pertuzumab to the established combination of trastuzumab and docetaxel has shown improved efficacy with acceptable toxicity in mBC (Swain et al. Lancet Oncol 2013;14:461-71); they are considered standard of care. Subcutaneous (SC) and IV trastuzumab formulations have shown comparable efficacy but SC administration is preferred by pts for reducing duration of clinic visits (Pivot, et al. Lancet Oncol 2013;14: 962–970). The combination of IV pertuzumab and SC trastuzumab has not been studied. The aim is to assess safety, tolerability, and efficacy of combining IV pertuzumab with SC trastuzumab and a taxane, as first-line therapy in pts with HER2-positive mBC.

Trial Design: SAPPHIRE is an open-label, multicentre, Phase IIIb study. Pts will receive IV pertuzumab every 3 weeks with a loading dose of 840 mg and subsequent doses at 420 mg combined with SC trastuzumab at 600 mg/5 mL every 3 weeks and a taxane (docetaxel, paclitaxel, or nab-paclitaxel; regimen determined by the investigator). Treatment will continue until disease progression, unacceptable toxicity, or pts withdraw consent, whichever occurs first. The study is expected to run for 42 months.

Eligibility: Pts aged ≥18 years old with histologically or cytologically confirmed HER2-positive [immunohistochemistry (IHC) positive at 3+ or in situ hybridisation-positive (ISH+)] mBC with at least one measurable lesion and/or non-measurable disease according RECIST version 1.1 and ECOG performance status (PS) 0-2 are eligible.

Specific Aims: The primary objective is to assess the safety and tolerability of combining IV pertuzumab with SC trastuzumab and investigator’s choice taxane chemotherapy. The secondary objectives are to assess the efficacy of the first-line combination of pertuzumab, trastuzumab, and taxane chemotherapy and second-line treatments for mBC after disease progression.

Statistical Methods: Primary safety analyses will report incidence and severity of adverse events (AEs)/serious AEs, AEs leading to premature discontinuation of study treatment and evidence of cardiac dysfunction. Secondary safety analyses will include exposure and duration of study treatment, ECOG PS and laboratory data. Secondary efficacy analyses will report the overall response rate, progression-free survival, event-free survival and overall survival. Continuous data will be summarised using mean, median, range, standard deviation, and standard error. Discrete data will be summarised using frequency counts and percentages. Time-to-event analyses will be based on Kaplan-Meier methodology.

Accrual: The planned 50 pts will be recruited from 13 Australian Centres. The study started in December 2013 with 24 pts now enrolled. Clinicaltrials.gov#NCT02019277.
A phase 2 study of eribulin in combination with pertuzumab and trastuzumab for advanced or recurrent human epidermal growth factor receptor 2 (HER2)-positive breast cancer (SONG-02)

Hajime Abe, Shunji Kamigaki, Yoshifumi Komoike, Nobuki Matsunami, Yoshiaki Nakano, Kenji Tezuka, Junji Tsurutani, Jun Yamamura and Keiichi Yamazaki.

1 Bell Land General Hospital, Sakai, Japan; 2 Sakai City Hospital, Sakai, Japan; 3 Kinki University Faculty of Medicine, Osakasayama, Japan; 4 Osaka Rosai Hospital, Sakai, Japan; 5 Kaizuka City Hospital, Kaizuka, Japan and 6 NHO Kinki-Chuo Chest Medical Center, Sakai, Japan.

Body: Background: Pertuzumab, an anti-HER2 humanized monoclonal antibody that inhibits receptor dimerization, has a mechanism of action that is complementary to that of trastuzumab, and the combination of pertuzumab plus trastuzumab plus taxanes, when used as first-line treatment for HER2-positive metastatic breast cancer, significantly prolonged progression-free survival (PFS). However, in the second and later line treatment of HER2-positive advanced or recurrent breast cancer, it has not settled whether it should be treated with pertuzumab plus trastuzumab plus chemotherapy or with trastuzumab plus chemotherapy. Eribulin mesylate is a non-taxane microtubule dynamics inhibitor that has been proved to prolong the overall survival of advanced or recurrent breast cancer patients compared with the treatment of physician's choice. The benefit of eribulin in combination with trastuzumab for patients with locally recurrent or metastatic HER2-positive breast cancer has been reported. However, the efficacy and safety of eribulin in combination with pertuzumab and trastuzumab for advanced or recurrent HER2-positive breast cancer patients has not been reported. The purpose of this study is to evaluate the efficacy and safety of eribulin in combination with pertuzumab and trastuzumab as second and later line therapy for patients with advanced or recurrent HER2-positive breast cancer.

Trial Design: This is a multicenter single arm phase 2 study for advanced or recurrent HER2-positive breast cancer patients who have experienced progression with anti-HER2 therapy. Patients received eribulin mesylate 1.4mg/m² administered via intravenous (IV) infusion over 2 to 5 minutes on Days 1 and 8 each 21-day cycle and pertuzumab 840mg/kg IV and trastuzumab 8mg/kg IV over 90 minutes on Day 1 of Cycle 1. Thereafter eribulin mesylate 1.4mg/m² and pertuzumab 420mg/kg and trastuzumab 6mg/kg was infused each 21-day cycle until disease progression or the appearance of toxic effects that could not be effectively managed. The primary endpoint is PFS of the combination therapy, based on local assessment of response using RECIST 1.1 criteria. Secondary endpoints are overall response rate (ORR), safety and tolerability. In addition, we examine PFS and safety according to the most recent treatment regimen. The study was conducted in accordance with the Declaration of Helsinki (2008), and the protocol and informed consent forms were submitted for approval to institutional review boards by the primary investigators. All patients provided written informed consent before undergoing any study-related procedures.

Statistical Method: All efficacy analyses were based primarily on the full analysis set (FAS), which included all patients who received over 1 dose(s) of study treatment. The PFS and ORR were calculated 95% confidence intervals (CIs). Treatment of 39 evaluable patients with the identified phase 2 doses will detect this difference with a power of 80% and alpha=5% (one-sided test). Accounting for a 10% invaluable rate and lead-in patients, a total of 43 patients will be enrolled on the study. Clinical trial information UMIN000014107.
Title: Phase I, open-label study evaluating the safety and tolerability of LJM716, BYL719 and trastuzumab in patients with metastatic HER2+ breast cancer

Payal D Shah¹, Sarat Chandarlapaty¹, Gary Ulaner¹, Stephen Zamora¹, Valentina Sterlin¹, Alexia Iasonos¹, Maura N Dickler¹, Mary Ellen Moynahan¹, Clifford A Hudis¹, Jose Baselga¹ and Shanu Modi¹. ¹Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Background: Breast cancers that overexpress the human epidermal growth factor receptor 2 (HER2+) are driven by HER2/HER3/PI3K signaling. Single agent therapy against this pathway is only modestly effective due to redundant mechanisms of pathway activation and regulatory feedback loops. Drug combinations designed to directly inhibit multiple nodes simultaneously have proven synergistic in preclinical models. Single agents and doublets targeting HER2, HER3, and PI3K have thus far proven safe in clinical testing. Methods: We are conducting a phase I clinical trial of LJM716, a fully human monoclonal antibody against HER3, plus BYL719, a small molecule alpha-specific PI3K inhibitor, and trastuzumab, an approved human monoclonal antibody against HER2, in patients (pts) with HER2+ metastatic breast cancer (MBC). There will be dose-escalation and dose-expansion phases, with correlative serum and tumor tissue studies. The primary objective is to determine the MTD of BYL719 with fixed dose LJM716 and trastuzumab in pts with HER2+, PIK3CA mutated MBC; determination of MTD will utilize the Continual Reassessment Method (CRM). LJM716 will be administered at 20mg/kg and trastuzumab at 2mg/kg, both intravenously weekly; starting dose of BYL719 will be 250mg orally daily, with dose escalation to MTD. Secondary objectives are to describe safety (CTCAE 4.0) and preliminary efficacy (RECIST v1.1) of the combination and to describe immunogenicity of LJM716. Exploratory objectives are to assess pre-treatment (tx) genomic alterations predictive of response or resistance to the tx; to assess proteomic pharmacodynamics markers of effective HER2, HER3 and PI3K inhibition, and to correlate cell-free DNA mutant allele fraction with clinical response. For these correlative studies, all pts will undergo serial plasma collection for cell-free DNA, and 10 pts will undergo pre-tx, on-tx, and at-progression biopsies. Eligible pts for dose-escalation and expansion are required to have ECOG 0-1, HER2+ MBC (immunohistochemistry 3+ or in-situ hybridization ≥ 2.0), and prior treatment with pertuzumab and ado-trastuzumab emtansine. For dose-escalation, pts may have measurable or non-measurable disease and somatic PIK3CA mutations are required. For dose-expansion, pts must have measurable disease and there will be two cohorts: one for wild-type and the other for mutant PIK3CA tumors. Accrual beginning June 2014 will include an anticipated 18 pts for dose-escalation and 30 pts for the expansion. Contact modis@mskcc.org for further information.

2014 San Antonio Breast Cancer Symposium

Publication Number: OT3-1-06
Average Grade: 4.17

Title: A phase 2 single-arm study to evaluate the clinical activity, safety and tolerability of enzalutamide (ENZA) with trastuzumab in patients with advanced human growth factor receptor 2 (HER2)-positive breast cancer

Maureen E Trudeau1, Eric Winer2, Joyce L Steinberg3, Maggie Liosatos3, Srinivasu Poondru3, Michael Dydo3, Yun Zhou2, Michael Westphal3, Amy C Peterson4 and William Gradishar5. 1Sunnybrook Health Sciences Center, Toronto, Canada; 2Dana-Farber Cancer Institute, Boston, MA; 3Astellas Inc, Northbrook, IL; 4Medivation Inc, San Francisco, CA and 5Northwestern University, Chicago, IL.

Body: Background
Androgen receptor (AR) expression is observed in ~60% of patients (pts) with HER2+ breast cancer1. In vitro, ENZA inhibits proliferation of AR+/HER2+ cell lines and enhances the activity of trastuzumab. ENZA also inhibits proliferation of trastuzumab resistant HER2 positive cells2.

Methods
Any amount of AR expression (local or central) is allowed, submission of tissue is mandatory. Patients must have measurable disease per RECIST 1.1, and have received 1 to 4 prior lines of anti-HER2 therapy in the advanced / metastatic setting. Brain imaging is required to exclude patients with CNS metastases. Pts with a seizure history are excluded.
Women with metastatic or locally advanced HER2+, AR+, and ER-/PgR- breast cancer will receive daily ENZA (160 mg) continuously and trastuzumab (6 mg/kg) administered every 21 days, until disease progression (NCT02091960). The primary endpoint (EP) is clinical benefit rate (CBR) where benefit is defined as complete or partial response (CR or PR) or stable disease (SD) ≥24 weeks according to RECIST 1.1 criteria. Additional EPs include safety and tolerability, and the relationship between AR expression and ENZA activity. If the CBR is ≥3 in 21 evaluable pts, the sample size will increase to 66 pts.

The primary EP will be analyzed in pts with centrally confirmed AR expression (≥10% nuclear staining by IHC), who have received at least one dose of ENZA, and have ≥1 post-baseline tumor assessment. The null hypothesis (H0), that the true CBR is 10%, will be tested against a 1-sided alternative. This Simon’s two-stage design yields 90% power when the true response rate is 25% with a 1-sided type 1 error rate of 5%. Enrollment is expected to continue through 2016.

MotHER: A US registry for women with breast cancer who have received trastuzumab, pertuzumab in combination with trastuzumab, or trastuzumab emtansine (T-DM1) during pregnancy or within 7 months prior to conception

Vikki Brown¹, Richard K Miller², Laura Chu³, Cheryl Chow³, Caroline Trudeau³ and Elizabeth B Andrews⁴. ¹INC Research, Raleigh, NC; ²University of Rochester School of Medicine and Dentistry, Rochester, NY; ³Genentech, San Francisco, CA and ⁴RTI International, Research Triangle Park, NC.

Body: Background: Trastuzumab (Herceptin) and pertuzumab (Perjeta) are HER2-targeted monoclonal antibodies, and T-DM1 (Kadcyla) is a HER2-targeted antibody–drug conjugate. These molecules are classified as FDA Pregnancy Category D, indicating evidence of fetal harm; there have been postmarketing reports of oligohydramnios in women who received trastuzumab during pregnancy; in non-clinical studies of pertuzumab, oligohydramnios, delayed renal development, and embryo-fetal death occurred in pregnant cynomolgus monkeys. Furthermore, maytansine, the parent molecule of DM1, has demonstrated embryotoxicity in mice. The MotHER pregnancy registry was established in 2008 as an FDA postmarketing commitment to evaluate the effects of trastuzumab on pregnancy outcome. Pertuzumab and T-DM1 were included in the registry following their respective FDA approvals in 2012 and 2013.

Study design: MotHER is a US pregnancy registry and uses a prospective, observational cohort design. Enrollment is voluntary and can be initiated by the patient or her healthcare provider. Women are followed up until pregnancy outcome; infants are followed up through the first year of life.

Eligibility criteria: Pregnant women ≥18 years of age and resident in the US are eligible if they have received at least one dose of trastuzumab, pertuzumab in combination with trastuzumab, or T-DM1 for breast cancer during pregnancy or within 7 months prior to conception. Enrollment must be initiated before pregnancy outcome is known.

Specific aims: The primary outcome measures are pregnancy outcomes and the incidence of pregnancy complications, such as oligohydramnios, congenital anomalies, and fetal/infant functional deficits. Information on potential birth defects, noted either at birth or during pediatric follow-up, is evaluated and classified by a birth defect evaluator/clinical geneticist.

Statistical methods: The study is descriptive and not designed for formal hypothesis testing; event rates with 95% confidence intervals will be calculated.

Accrual: There is no pre-specified sample size. Data collection is ongoing, from 2009 to 2019 for trastuzumab, from 2012 to 2022 for pertuzumab plus trastuzumab, and from 2013 to 2023 for T-DM1. Fourteen women have enrolled as of January 31, 2014.
**Title:** A phase II, randomized study of T-DM1 versus T-DM1 plus short induction with docetaxel in first line treatment for locally advanced or metastatic HER2+ breast cancer (SOLTI-1203)

Antonio Llombart\(^1\), Javier Cortés\(^2\), Eva Ciruelos\(^3\), Xavier González\(^4\), Lorena de la Peña\(^5\), Patricia Villagrasa\(^6\), Elena Bernedo\(^6\), Katya Moreno\(^6\), Susanne Meyra\(^6\) and Jose Baselga\(^7\). \(^1\)Hospital Universitari Arnau de Vilanova de Valencia, Valencia, Spain; \(^2\)Hospital Universitari Vall d'Hebron, Barcelona, Spain; \(^3\)Hospital Universitario 12 de Octubre, Madrid, Spain; \(^4\)Hospital Universitari Quirón Dexeus, Barcelona, Spain; \(^5\)SOLTI Breast Cancer Research Group, Barcelona, Spain; \(^6\)Hoffmann-La Roche, Ltd, Basel, Switzerland and \(^7\)Memorial Sloan Kettering Cancer Center, New York, NY.

**Body: Background:** This study is founded upon the hypothesis that the addition of a short induction phase with docetaxel to the treatment with T-DM1 can improve efficacy with respect to T-DM1 administered as a single agent, in patients with advanced HER2 positive breast cancer who have not received previous treatment for the advanced disease. The rational for this approach is based on the results of the phase II randomized study of T-DM1 versus docetaxel trastuzumab, in which the administration of T-DM1 to the patients resulted in a statistically significant and clinically relevant improved progression free survival (PFS). One important observation with respect to this comparative study is that, in the T-DM1 arm, a higher number of patients progressed during the first six months than in the docetaxel trastuzumab arm. The existence of T-DM1 resistant patients, who progress during the first 6 months, highlights the need to explore new combinations with cytotoxic agents to induce an early response.

**Study design:** This is a phase II, prospective, randomized, open label, research study with two groups designed to assess the efficacy of T-DM1 together with short induction with docetaxel (SI docetaxel) versus T-DM1monotherapy treatment, in patients recently diagnosed with locally advanced or metastatic, progressive or recurrent, HER2+ breast cancer, who have not received previous chemotherapy for the advanced disease. The randomization will be carried out at a 1:1 ratio to one of the following two groups: 1.Monotherapy treatment regimen with T-DM1 at a dose of 3.6 mg/kg every 3 weeks until treatment finalization, 2.T-DM1 at a dose of 3.6 mg/kg on Day 1 and every 3 weeks until treatment finalization, together with docetaxel 60 mg/m² on Day 1 and every 3 weeks for a total of 4 treatment cycles.

**Eligibility criteria:** Female adults recently diagnosed with progressive or recurrent, locally advanced or metastatic HER2+ breast cancer, who have not received previous chemotherapy for the advanced disease.

**Endpoints:** The primary endpoint is to compare the early efficacy of the combination of T-DM1 together with SI docetaxel versus monotherapy treatment with T-DM1 measured as the PFS rate at 4 months. Secondary endpoints include comparison of the ORR, CBR, DR and OS of the combination versus monotherapy treatment. Exploratory endpoints consist to assess if the PAM50 intrinsic subtypes (HER2-enriched in comparison with the rest) predict benefit of T-DM1 plus SI docetaxel or T-DM1 as monotherapy treatment, in terms of ORR and PFS.

**Statistical methods:** The considerations for the sample size are based on obtaining a statistical power of 80 % to be able to detect a difference in the rate of PFS at 4 months of 8% (83% in group A and 91% in group B), with a bilateral significance level of 5% and supposing a patient withdrawal rate of 10%. According to these calculations, the sample size is estimated at 236 patients. The analysis of the primary endpoint will be based on the Kaplan Meier estimate analysis.

**Target accrual:** Approximately 40 European sites from Spain, Portugal and Austria will be participating. The FPI is planned in October 2014.
Title: Combination immunotherapy with trastuzumab and the HER2 vaccine E75 (nelipepimut-S) in high-risk HER2+ breast cancer patients to prevent recurrence

Beth A Mittendorf1, Erika J Schneble1, Nuhad K Ibrahim2, Julia M Greene1, John S Berry1, Alfred F Trappey1, Guy T Clifton1, Jarrod P Holmes4, Sathibalan Ponniah3 and George E Peoples1. 1San Antonio Military Medical Center, San Antonio, TX; 2MD Anderson Cancer Center, Houston, TX; 3Cancer Vaccine Development Lab, Uniformed Services of Health Sciences, Bethesda, MD and 4Redwood Regional Medical Group, Santa Rosa, CA.

Body: Background: In an adjuvant phase II trial, the HER2-derived nelipepimut-S (E75) + GM-CSF vaccine (Neuvax) has been shown to reduce breast cancer recurrence. Preclinical testing of the combination of trastuzumab (Tz) and nelipepimut-S has shown synergistic cytolysis against HER2 expressing cancer cells. In pilot phase II data in HER2+ patients (pts), 55 pts dosed with CD8-eliciting HER2 derived peptide vaccines sequentially after treatment with Tz resulted in no recurrences at 36 months median follow-up compared with a 16% recurrence rate in 34 randomized controls treated with Tz without vaccine (p=.012). Based on these data, we have designed a trial to evaluate the ability of the combination of Tz and the E75 vaccine concurrently to prevent recurrence in pts with high-risk, HER2+ breast cancer.

Trial Design: This study will be a multicenter, prospective, randomized, single-blinded, phase II trial evaluating adjuvant Tz + NeuVax (E75+GM-CSF) vs. Tz + GM-CSF alone in high-risk HER2+ (IHC 3+ and/or FISH ≥2.2) breast cancer pts. High-risk pts include: 1) those that did not achieve a pathologic complete response (pCR) after neoadjuvant chemotherapy and HER2-targeted therapy or 2) those treated with upfront surgery that are node positive (≥ 4+ LN or 1-3+ LN if hormone receptor negative). Pts must be HLA-A2/A3+ to be eligible (E75 is HLA-A2/A3-restricted) with ECOG performance status 0-1. Pts will be enrolled after completing standard of care multi-modal therapy but prior to the 3rd dose of Tz maintenance therapy (monotherapy). Pts will be randomized 1:1 to receive either NeuVax or GM-CSF alone which will be administered as six monthly intradermal inoculations concurrently with Tz therapy. Pts will then receive four booster inoculations of either NeuVax or GM-CSF every 6 months. The primary efficacy endpoint is to compare disease-free survival (DFS) between treatment arms. Secondary objectives will include evaluation of local and systemic toxicity, distant recurrence free survival, and in vivo/in vitro immunologic responses. From previously published experience with Tz, we expect a recurrence rate of 20% in Tz (plus GM-CSF) treated pts and anticipate that the combination of Tz with E75+GM-CSF will reduce this recurrence rate to 5%. In order to show statistical difference between these recurrence rates, we plan to enroll 50 pts per treatment arm (100 total) with a type I error rate of 5% and 80% power to detect the primary endpoint. Trial accrual is anticipated to begin in September of 2014, with a two year period for trial enrollment followed by a three year follow-up period.

Conclusion: We hypothesize that combination adjuvant immunotherapy with Tz and NeuVax will result in a greater reduction in breast cancer recurrence than Tz therapy alone. We have designed a prospective, randomized, single-blinded, phase II trial evaluating the efficacy of this immunotherapy combination in high-risk HER2+ breast cancer pts to test this hypothesis.

Contact Information: This trial is funded by a DoD grant to EAM with matching funds from Galena Biopharma and is being conducted with the assistance of the academic CRO, Cancer InCITe, LLC.
**Title:** HERmione: A Phase 2, randomized, open label trial comparing MM-302 plus trastuzumab with physician’s choice of chemotherapy plus trastuzumab, in anthracycline naive HER2-positive, locally advanced/metastatic breast cancer, previously treated with pertuzumab and trastuzumab emtansine (T-DM1)

Kathy Miller¹, Javier Cortes², Sara A Hurvitz³, Ian E Krop⁴, Debu Tripathy⁵, Sunil Verma⁶, Kaveh Riahi⁷ and Denise A Yardley⁸.

¹Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN; ²Vall d’Hebron Institute of Oncology, Barcelona, Spain; ³University of California, Los Angeles, CA; ⁴Dana-Farber Cancer Institute, Boston, MA; ⁵MD Anderson Cancer Center, Houston, TX; ⁶Sunnybrook Odette Cancer Centre, Toronto, ON, Canada; ⁷Merrimack Pharmaceuticals, Inc, Cambridge, MA and ⁸Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN.

**Body:** Background: Despite improvements in treatment with newly approved HER2-targeted therapies such as pertuzumab and trastuzumab emtansine (T-DM1), HER2-positive metastatic breast cancer (MBC) remains a serious and life-threatening disease. MM-302 is an antibody drug conjugated liposomal doxorubicin targeted to HER2. The present Phase 2 study was developed based upon data from a recently reported Phase 1 study (SABCS 2013, Munster, et al., #P4-12-29) in 47 heavily pretreated HER2-positive MBC patients treated with MM-302 alone or in combination with trastuzumab, with more benefit being seen in patients without prior anthracycline exposure. In that study, MM-302 appeared to have an acceptable safety profile and, importantly, no clinically significant declines in left ventricular ejection fraction (LVEF) were observed.

Trial design: HERmione is a randomized Phase 2, two-arm, open-label trial designed to evaluate if MM-302 can address an unmet medical need in treating anthracycline naive patients with HER2-positive metastatic breast cancer who have previously received pertuzumab and T-DM1 in the locally advanced or metastatic setting. Patients are randomly assigned 1:1 to MM-302 (30 mg/m², IV q3w) plus trastuzumab (6 mg/kg, IV q3w) or a chemotherapy of physician’s choice (chosen from vinorelbine, capecitabine, or gemcitabine) plus trastuzumab (6 mg/kg, IV q3w). Patients will be stratified according to geographic region, presence of visceral disease, and ≥ 4 prior chemotherapy-containing regimens for metastatic disease.

Eligibility criteria: HER2-positive locally advanced or MBC (HER2 confirmed by central lab); prior trastuzumab in any setting, prior pertuzumab and T-DM1 exposure in the incurable locally advanced or metastatic setting; unlimited prior lines of therapy; ECOG 0-1, and LVEF ≥ 50%. Patients with prior anthracycline exposure in any setting are excluded. Central nervous system metastases are permitted, if stable and without symptoms or steroids for 4 weeks after treatment. Patients with significant cardiac dysfunction or risk of cardiac dysfunction are excluded.

Specific aims: The primary efficacy endpoint is independently assessed progression free survival (PFS) with tumor response evaluated based on RECIST version 1.1. Secondary endpoints include Investigator Assessed PFS, Overall Survival (OS), 6 and 12 month OS rate, Time to Treatment Failure, Objective Response Rate, Duration of Response, Clinical Benefit Rate, safety and toxicity, Patient Related Outcomes and pharmacokinetic exposure. Safety assessments include all adverse events, abnormal laboratory values, cardiac events, and LVEF decline.

Statistical methods: A total sample size of 250 subjects will be enrolled to observe 191 PFS events for 90% power to detect a Hazard Ratio of 0.625. The MM-302 arm will be compared to the control arm on the primary endpoint of PFS using a stratified log-rank test at a one-sided 0.025 level.

Accrual status: Recruitment is planned to start in July 2014 at approximately 60 sites in the United States and Western Europe.
**Title:** IMPACT: IMaging PAtients for Cancer drug selecTion – Metastatic breast cancer (MBC)

Frederike Bensch¹, Adrienne Brouwers¹, Andor Glaudemans¹, Johan de Jong¹, Erik de Vries¹, Winette van de Graaf², Eline Boon², Wim Oyen², Lioe-Fee de Geus-Oei², Eric Visser², Eric van Helden³, Willemien Menke-van der Hoeven van Oordt³, Henk Verheul³, Otto Hoekstra³, Jim Janssen³, Marc Huisman³, Sjoerd Elias⁴, Carl Moons⁴, Liesbeth de Vries¹ and Carolien Schröder¹. ¹University Medical Center Groninge, Netherlands; ²Radboud University Medical Center Nijmegen, Netherlands; ³VU Medical Center, Amsterdam, Noord-Holland, Netherlands and ⁴University Medical Center, Netherlands.

**Body:**

**Background:** Therapy of newly identified MBC is largely based on estrogen receptor (ER) and human epidermal growth factor receptor 2 (HER2) status. Optimal receptor information should be up-to-date and preferably from the whole body, given receptor conversion over time and intra-patient tumor heterogeneity. Novel molecular imaging by means of $^{18}$F-fluoroestradiol (FES)- and $^{89}$Zr-trastuzumab-PET/CT is a non-invasive, patient friendly way to obtain such information. Comprehensive prospective data comparing novel molecular imaging, metastasis biopsy and blood biomarkers, are needed to assess clinical utility for optimal therapy guidance and response prediction.

**Trial design:** The IMPACT-MBC trial (NCT01957332), is a multicenter prospective cohort study, supported by the Dutch Cancer Society-Alpe d’HuZes, in which $n=200$ newly diagnosed MBC patients will be entered. Prior to start of treatment patients will undergo i) standard MBC work up including bone scan, diagnostic CT and $^{18}$F-fluorodeoxyglucose(FDG)-PET/CT, ii) a metastasis biopsy, for standard (immuno)pathology and DNA sequencing, iii) $^{18}$F-FES- and $^{89}$Zr-trastuzumab-PET/CT to assess whole-body metastatic ER and HER2 status, and iv) blood sampling (CTCs, ctDNA, germline DNA, $^{89}$Zr-radioactivity measurements).

Treatment advice will be based on standard work up and experimental PET scans. Tumor response is assessed by a 2 week $^{18}$F-FDG-PET/CT (experimental) and an 8 week diagnostic CT (standard; primary outcome).

**Eligibility criteria:** All newly diagnosed non-rapidly progressive MBC patients with measurable or clinical evaluable (bone only) disease can be enrolled, regardless of primary tumor ER and HER2 status. Patients should be eligible for systemic therapy, but not require immediate start of chemotherapy. A histological biopsy of a metastatic lesion should be safely obtainable. Excluded are pregnant or lactating women and patients with a prior allergic reaction to immunoglobulins.

**Specific aims:** i) To assess the (added) clinical utility of $^{18}$F-FES- and $^{89}$Zr-trastuzumab-PET/CT, in the setting of MBC at first presentation, in relation to other diagnostics, ii) to assess the relation of experimental $^{18}$F-FES-, $^{89}$Zr-trastuzumab- and 2 week $^{18}$F-FDG-PET/CT with (progression free) survival and iii) to assess the cost-effectiveness of the experimental PET/CT scans.

**Statistical methods:** IMPACT-MBC aims to model the predictive value of several tests (novel molecular imaging, biopsy and blood biomarkers) in combination, by means of multivariable regression-model based techniques, combined with state-of-the-art methods for estimating the added value of novel tests to existing information (e.g. NRI, IDI). All these analyses will be employed both on (predicting responsiveness on) a patient- and metastasis level.

**Present accrual and target accrual:** The IMPACT-MBC trial was opened for accrual at the University Medical Center (UMC) Groningen, in August 2013. Accrual rate is as anticipated 2-3 patients/month/center. The two other participating centers, Radboud MC Nijmegen and VUmc Amsterdam recently opened. It is anticipated that accrual of patients will be finalized in 2016.

Title: MINT I: Multi-Institutional Neo-adjuvant Therapy, MammaPrint Project I

Charles E Cox¹, Peter Blumencranz², Ruben Saez³, Robert Wesolowski⁴, William Dooley⁵, Lisette Stork-Sloots⁶, Femke de Snoo⁶, Sarah Untch⁷ and Eli Avisar⁷. ¹University of South Florida, Tampa; ²Morton Plant Hospital, Clearwater; ³Plano Cancer Institute, Plano; ⁴Ohio State University; ⁵University of Oklahoma; ⁶Agendia Inc, Irvine, CA and ⁷Miller School of Medicine, University of Miami, Miami, FL.

Body: Background:
Women with locally advanced breast cancer (LABC) are often treated with neo-adjuvant chemotherapy to reduce the size of the tumor prior to surgery, to enable breast conserving surgery and to observe the clinical effect of therapy in real time. Studies have shown that the 25–27% of individuals who have a pathologic complete response (pCR) to neoadjuvant therapy have a survival advantage of 80% in 5 years, which is double the expected survival of the remaining patients without pCR. If patients who are likely to show a pCR could be identified prior to initiation of therapy, it would enable more informed treatment decisions – patients likely to respond would be served well by current neoadjuvant chemotherapy protocols, while those unlikely to respond may be better suited to innovative new strategies for drug discovery [von Minckwitz et al. JCO 2006]. Genomic assays, which are widely used to provide prognostic and predictive information in early breast cancer, have the potential to provide information on the likelihood of a patient with LABC responding to neo-adjuvant therapy [Glück et al. BRCRT2013].

Trial design:
MINT I is a prospective study designed to test the ability of molecular profiling, as well as traditional pathologic and clinical prognostic factors, to predict response to neo-adjuvant chemotherapy in patients with LABC. MammaPrint risk profile, BluePrint molecular subtyping profile, TargetPrint estrogen receptor (ER), progesterone receptor (PR) and HER2 single gene readout, and TheraPrint Research Gene Panel will be analyzed on a fresh tumor specimen using the whole genome array. Patients will receive neo-adjuvant chemotherapy pre-specified in the protocol. Response will be measured centrally. pCR is defined as the absence of invasive carcinoma in both the breast and axilla at microscopic examination of the resection specimen, regardless of the presence of carcinoma in situ.

Eligibility:
The study will include women ≥18 years with histologically-proven invasive breast cancer T2 (≥3.5cm)-T4, N0M0 or T2-T4N1M0, adequate bone marrow reserves and normal renal and hepatic function who signed an IRB approved informed consent.

Objectives:
The objectives of the study are to:
1. Determine the predictive power of MammaPrint and BluePrint for sensitivity to neo-adjuvant chemotherapy as measured by pCR.
2. Compare TargetPrint ER, PR and HER2 with local and centralized IHC and/or CISH/FISH assessment.
3. Identify correlations between TheraPrint and response to neo-adjuvant chemotherapy.
4. Identify and/or validate predictive gene expression profiles of clinical response or resistance to neo-adjuvant chemotherapy.
5. Compare BluePrint with IHC-based subtype classification.

Statistical methods:
Standard statistical tests such as the Pearson Chi-square test will be used to characterize and evaluate the relationship between chemoresponsiveness and gene expression patterns.

Accrual:
A total of 226 eligible patients will be enrolled from multiple institutions. To date (June 06, 2014), 103 patients have been enrolled.
**Title:** Prospective observational study of clinical outcomes for the NanoString® technologies Prosigna™ test by the West German Study Group

**Body:**

**Background:** Current diagnostic tools for breast cancer (BC), including screening, diagnostic breast imaging and biopsy, do not provide information about subtype classification. However, the subtype classification is crucial for the assessment of the recurrence risk and for the choice of optimal adjuvant treatment. A vast amount of data from recent research, clinical trials, and peer reviewed publications support the value of intrinsic subtyping based on gene expression analyses to assess prognosis and treatment options for patients with early BC.

**Trial design:** The multicenter (n=8), prospective study examines whether the Prosigna™ test influences physician and patient adjuvant treatment selection over and above currently used prognostic factors. It also examines the impact of the test results on patients’ reported outcomes including their decisional conflict status, anxiety levels, and functional status.

Prosigna™ is a standardized test measuring the expression levels of 50 classifier genes in formalin-fixed, paraffin-embedded tissue samples and provides a subtype classification based on the fundamental biology of individual patient’s tumor (intrinsic subtyping), as well as a prognostic score (risk of recurrence (ROR) score) that predicts the probability of cancer recurrence over 10 years.

**Eligibility criteria:** Postmenopausal women with resected N0, estrogen-receptor-positive (ER) (by immunohistochemistry (IHC); >1% of stained tumor cells is considered positive), HER2-negative (IHC and/or in-situ fluorescence hybridization by local laboratory), early-stage invasive BC (T1-T2, pN0 (i+/mol+), M0). Patients must be able to give consent and must be eligible for treatment with adjuvant chemotherapy (Ctx) (ECOG performance status ≤ 1).

Patients with non-invasive (e.g. Paget’s disease, DCIS), ER-negative or HER2-positive BC must not be included. Metastatic disease and contraindications for adjuvant Ctx (age, ECOG >1, significant comorbidities) are exclusion criteria. Patients unable to complete patient reported outcome surveys will be excluded.

**Specific aims:**

**Primary endpoint** is the proportion of patients whose choice of treatment is changed as a result of receiving the Prosigna™ result.

**Secondary endpoints** include the proportion of patients whose choice of treatment is changed stratified by ROR groups (low, intermediate, high) and who have cancer recurrence risk proximal to the cutoff points between risk strata (± 5% from cutoff point). Investigators’ confidence in treatment recommendations before/after Prosigna™ results and change in patients’ decisional conflict status, anxiety levels, and functional status, stratified by cancer recurrence risk strata, will be investigated. Rate and severity of treatment-related adverse events stratified by whether patient received adjuvant Ctx and agreement in molecular subtyping between Prosigna™ and local IHC will be evaluated.

**Statistical methods:** Sample size of 200 produces a one-sided 95% lower-limit CI with a distance from the sample proportion to the lower limit that is equal to 0.05 when the sample proportion is 0.25.

Present and target accrual: A total of 200 patients will be included, current accrual is n=111 as of 3rd June 2014.
Title: ADAPT - Adjuvant Dynamic marker-Adjusted Personalized Therapy trial optimizing risk assessment and therapy response prediction in early breast cancer

Ulrike Nitz¹,², Oleg Gluz¹,², Raquel von Schumann¹,², Daniel Hofmann¹, Ronald E Kates¹, Sherko Kuemmel³, Michael Braun⁴, Claudia Schumacher⁵, Benno Nuding⁶, Bahriye Aktas⁷, Helmut Forstbauer⁸, Nicolai Maass⁹, Mahdi Rezai¹⁰, Stefan Kraemer¹¹, Mathias Warm¹², Rachel Wuerstlein¹,¹³ and Nadia Harbeck¹,¹³.¹

Body: Background: Early therapy response is currently not regarded for further treatment decisions as standard of care in the treatment of breast cancer (BC). Predictive markers for the success of a certain therapy could support the physician’s choice of adequate and beneficial therapies by simultaneous reduction of unnecessary toxicity. Proliferation markers as Ki-67 seem to be a suitable tool, as dynamic changes of proliferation (as result of induction therapy) have been shown to be most important for outcome of neoadjuvant chemotherapy prediction in patients with pCR in distinct BC subtypes (luminal B, TNBC, HER2+).

Methods: Trial design: ADAPT combines early assessment of prognosis by conventional markers (e.g. molecular classification, nodal status) with dynamic measurement of proliferation changes during a 3-week induction therapy, using baseline diagnostic core biopsy and a second biopsy after induction therapy. ADAPT consists of an umbrella trial and five different sub-trials (HR+/HER2-, HR+/HER2+, HR-/HER2+, HR-/HER2-, Elderly) and is set up as prospective, multi-center, controlled, non-blinded, randomized phase II/III trial.

- HR+/HER2-: endocrine therapy (ET) vs. chemotherapy (4xPac q2w – 4xEC q2w vs. 8xNab-Pac q1w – 4xEC q2w) + ET, depending on risk classification/early response.
- HER2+/HR+: T-DM1 vs. T-DM1 + ET vs. trastuzumab + ET.
- HER2+/HR-: Trastuzumab + Pertuzumab ± Paclitaxel q1w.
- TN: Nab-Paclitaxel + Gemcitabine vs. nab-Pac + Carboplatin.
- Elderly: 2xMyocet + Cyclophosphamide q3w, depending on cPR/cCR or NC/toxicity the treatment will be continued for two more cycles or changed to 6xPac q1w.

Adaptation/change in therapy regimens can be made by interim analysis after n=130 in each sub-trial. Eligibility criteria: Histologically confirmed unilateral primary invasive BC with known HR-/HER2-status (central pathology) for allocation to the respective sub-trial. Pts requiring chemo- or targeted (anti-HER2) therapy must have adequate laboratory values and organ function and must have no contraindications for the planned treatment.

Primary endpoints: Evaluation of dynamic test for outcome prediction/prospective comparison of 5yr EFS in responders (intermediate risk (RS 12-25) / good response to short-term ET in HR+/HER2- or pts with pCR in HER2+/TN BC) compared to low risk HR+/HER2- (RS≤11, N0-1) pts (control group).

Statistical methods: Assumption across sub-protocols: adjuvant CTx can be spared in HR+/HER2- or pCR be achieved in HER2+/TN in expected 1200 (HR+/HER2-) or 170 (HER2+/TN) pts, respectively. Outcome will be compared to the control group (expected n=640 HR+/HER2- pts: low risk (by RS), i.e. no CTx). Assuming 94% 5yr survival in control group, one-sided test of non-inferiority at 95% CI will have 80% power for survival non-inferiority margin of 3.2% (i.e. 90.8% survival).

Present and target accrual: By June 2014, 73 active sites have recruited 1820 pts for ADAPT HR+/HER2-. Target accrual is 4000 pts. 190 of 380 pts were successfully randomized for ADAPT HER2+/HR+. ADAPT HER2+/HR- has included 17 of 220 pts and ADAPT Triple Negative has recruited 150 of 336 pts.
Title: Improving outcomes in triple-negative breast cancer (TNBC) using molecular triaging and diagnostic imaging to guide neoadjuvant therapy

Stacy Moulder-Thompson¹, Wei Yang¹, Naoto T Ueno¹, Joe Ensor¹, Vicente Valero¹, Ricardo Alvarez¹, Jennifer Litton¹, Rashmi Murthy¹, Nuhad Ibrahim¹, Banu Arun¹, Beth Mittendorf¹, Kelly Hunt¹, Funda Meric-Bernstam¹, Helen Piwnica-Worms¹, Rosalind Candelaria¹, Debu Tripathy¹ and Fraser Symmans¹. ¹University of Texas MD Anderson Cancer Center, Houston, TX.

Body: BACKGROUND:
Known disparities exist in patients with TNBC treated using neoadjuvant chemotherapy (NACT) with 30-50% having excellent response to treatment (pCR/RCB-I) and good survival prognosis, while 50-70% demonstrate marked residual disease (RCB-II-III) with significantly worse prognosis. Lack of response early into NACT also indicates a low chance (5%) of achieving pCR. Thus, it is important to develop diagnostic platforms predictive of pCR, in order to direct patients with responsive disease toward standard NACT and non-responsive disease toward experimental therapies within clinical trials.

TRIAL DESIGN
This study will determine the impact of predicting response to NACT using both molecular and imaging diagnostics and will determine if offering a clinical trial of selected targeted therapy will impact outcomes (as measured by pCR and RCB) in predicted non-responsive disease. An algorithm that incorporates pre-defined genomic signatures will determine predicted sensitivity to chemotherapy (JAMA, 2011; 305:1873-81). All patients will undergo biopsy of the primary tumor for molecular analyses, but will then be randomized 2:1 to know these results (Arm A) versus not (Arm B). All patients will begin anthracycline-based NACT with diagnostic imaging to assess response after 4 cycles. Patients who fit molecular/imaging criteria for non-responsive disease will be offered a clinical trial based upon molecular profiling (Arm A) or based upon physician/patient choice (Arm B). Patients who fit criteria for responsive disease in either arm will continue with taxane based NACT.

ELIGIBILITY CRITERIA
INCLUSION: Candidate for biopsy of the primary tumor site; tumor size ≥ 1.5 cm diameter; TNBC by standard pathologic assays; ≥18 years of age; LVEF ≥ 50%; adequate organ and bone marrow function
EXCLUSION: Stage IV disease; history of invasive cancer within 5 years; excisional biopsy of the primary tumor; biopsy site changes that limit response assessment; medically unfit for chemotherapy; prior anthracycline; ≥grade II neuropathy; Zubrod performance status of >2; history of serious cardiac event

PRIMARY AIM
Primary Aim: to prospectively determine the impact of implementation of a research platform that includes molecular (genomic) testing from a primary tumor biopsy to predict response, and diagnostic imaging to assess response to standard NACT in patients with localized invasive TNBC. Secondary Aims: compare rates of clinical trial enrollment between study arms, compare DFS, integrated “prospective-retrospective” biomarker analysis, correlative science studies to identify therapeutic targets for resistant disease

STATISTICAL METHODS AND TARGET ACCRUAL
Success will be defined as an improvement in the rate of excellent pathologic response (pCR/RCB-I) from 50%-->64% using the triaging platform. A maximum of 360 patients will be randomized 2:1 to the experimental arm vs. the control arm using a group sequential design with one-sided O’Brien-Fleming boundaries, with up to two equally spaced binding interim tests for both futility and superiority and one final test, having an overall Type I error .05 and power .80 to detect a response rate improvement from a null rate of .50 to a target value of .642.
Title: NEOPAL: A randomized phase II study comparing RCB response to neoadjuvant chemotherapy or letrozole-palbociclib in PAM50 defined postmenopausal luminal breast cancer

Paul H Cottu¹, François Duhoux¹, Jérôme Lemonnier², Hervé Bonnefoi³, Anne Vincent Salomon¹, Bernard Asselain¹ and Suzette Delaloge⁴. ¹Institut Curie, Paris, France; ²UNICANCER, Paris, French Polynesia; ³Institut Bergonie, Bordeaux, France and ⁴Institut Gustave Roussy, Villejuif, France.

Body: Background: HR-positive BC heterogeneously sensitive to neoadjuvant chemotherapy (NEC), with pCR rates varying from 2 to 20% at most. The alternative systemic primary therapy in ER+ breast cancer is neoadjuvant endocrine therapy (NET). Clinical response with NET is roughly 50%. It has also been suggested that NET may yield a higher rate of breast conserving surgery than NEC in ER+ disease, although pCR remains under 10% in both instances. No definite pathological criteria for response to NET has been defined so far. Within this context, the PAM 50 signature has been evaluated on numerous series of pts and has been shown to highly correlate with Residual Cancer Burden (RCB – Symmans, JCO 2007) and pCR in patients treated with NEC, as well as with the PEPI score in patients treated with NET (Ellis 2011). Palbociclib + Letrozole has been shown as a very active association as first-line metastastic treatment of HR+ Her2- BC pts on both response rates and progression free survival (Paloma-1 study). This combination could represent an interesting alternative to CT in carefully selected Luminal BC pts.

Trial design and statistical methods: Open-label, randomized, parallel, multicenter, exploratory phase II study, comparing sequential standard NEC (3 FEC 100 followed by 3 Docetaxel 100) and a same duration letrozole + palbociclib combination as neoadjuvant treatment of stage II-IIIA PAM 50 defined Luminal A-Node+/Luminal B breast cancer. Medical treatment will be followed by adequate surgery and complementary chemotherapy and radiation therapy as clinically indicated. All pts will receive adjuvant chemotherapy. Randomizations are equally balanced between the 2 arms and stratified based on T2 versus T3-T4 and PAM 50 luminal A vs luminal B. A Fleming 2-step statistical design will be used in the experimental arm with an intermediate futility analysis. The target accrual is 60 pts evaluable for RCB in both arms.

Eligibility criteria: Newly diagnosed pts with ER+, Her2-negative, stage II-III breast cancer will be tested for PAM50 signature. Only luminal A N+ or Luminal B (PAM50 ROR (Prosigna™) centralized evaluation) pts will be eligible and randomized. Pts must be post-menopausal women, aged > 18 years, bear operable unilateral invasive BC, and not be candidate or uncertain for breast conservation.

Specific aims: The main objective of this trial is to evaluate the ability of each treatment strategy to provide RCB 0-I at surgery. Secondary end-points are: Clinical/radiological response rates in each treatment arm (RECIST 1.1), safety (CTC-AE V4.0), relative dose intensity of each drug in both arms, positive and negative predictive values of PAM50 ROR-defined status, assessment of several biomarkers as potential predictors of clinical and pathological response, rates of BCS, with regard to the initially planned surgery, all in both arms

Target accrual: This study has started in autumn 2014. 132 pts will have to be included (estimation of 10% risk of non evaluable pts). As about 10% of PAM50 evaluable pts will be classified as non luminal, and taking into account potential technical failures, about 180 pts will be screened.
Title: Predicting hormonal therapy response in breast cancer using diffuse optical spectroscopic imaging (DOSI): Ongoing clinical study

Thomas D OSullivan1, Anais Leproux1, Alice M Police1, Dorota Wisner2, Christine McLaren1, Wen-Pin Chen1, Albert E Cerussi1, Min-Ying Su1 and Bruce J Tromberg1. 1University of California, Irvine, CA and 2University of California, San Francisco, CA.

Body: Background: The goal of this multi-site prospective study is to validate a safe, painless imaging method to measure the change in breast density caused by hormonal chemotherapy treatments such as tamoxifen. Recent studies have demonstrated that hormonal therapies are more effective at reducing risk in women who exhibit >10% reduction in breast density compared to women who had little or no density change, suggesting that breast density is a predictor of tamoxifen effectiveness. Current methods to measure breast density include MRI and mammography, however frequent applications of these modalities are limited due to cost and x-ray exposure, respectively. Alternatively, we are testing an imaging method that uses safe near-infrared light to measure breast tissue physiology called diffuse optical spectroscopic imaging (DOSI).

Trial Design and Eligibility: The primary aim of the study is to determine whether the percentage change in the DOSI measurement of water correlates with the change in the MRI measurement of breast density after 18 months of treatment in the contralateral normal breast of breast cancer patients receiving tamoxifen. Other DOSI-derived parameters such as lipid content and hemoglobin concentration will be examined in secondary aims. Two groups of women are being recruited for the study: Pre-menopausal subjects receiving tamoxifen (treatment group) and pre-menopausal subjects not receiving chemoprevention agents (control group). Participants are measured with DOSI and non-contrast MRI before, and 6, 12 and 18 months after beginning tamoxifen. Eligible subjects are pre- and peri-menopausal females older than 21 years of age who have not and do not intend to receive chemotherapy, radiation, or surgical cancer treatment to the imaged breast, and are not pregnant or nursing. Study sites include the University of California, Irvine and San Francisco campuses.

Statistical Methods: At a 5% significance level, the pre-determined power of the study is sufficient to detect the difference between the treatment and control groups by measuring the percentage change in the DOSI measurement of water correlates with the change in the MRI measurement of breast density after 18 months of treatment in the contralateral normal breast of breast cancer patients receiving tamoxifen. Other DOSI-derived parameters such as lipid content and hemoglobin concentration will be examined in secondary aims. Two groups of women are being recruited for the study: Pre-menopausal subjects receiving tamoxifen (treatment group) and pre-menopausal subjects not receiving chemoprevention agents (control group). Participants are measured with DOSI and non-contrast MRI before, and 6, 12 and 18 months after beginning tamoxifen. Eligible subjects are pre- and peri-menopausal females older than 21 years of age who have not and do not intend to receive chemotherapy, radiation, or surgical cancer treatment to the imaged breast, and are not pregnant or nursing. Study sites include the University of California, Irvine and San Francisco campuses.

Accrual Update: Out of the target accrual of 36, 11 subjects (6 treatment and 5 control group) have been enrolled to date. Enrollment is open until 11/30/2015.
Title: PROMIS: PRospective study Of MammaPrint in breast cancer patients with an Intermediate recurrence Score (PROMIS)

Hatem Soliman¹, Sarah Untch² and Lisette Stork². ¹Moffitt Cancer Center, Tampa and ²Agendia Inc, Irvine, CA.

Body: Background:
Gene expression profiling in breast cancer offers the potential to improve prognostic accuracy, treatment choice, and health outcomes in women diagnosed with early-stage breast cancer. Numerous gene-profiling assays are now available, which can be applied to a single tumor specimen to provide physicians with a more complete basis for treatment decisions.

• MammaPrint is a 70-gene profile to estimate whether patients are at high or low risk of developing metastases within the first 10 years after curative surgery.
• BluePrint is an 80-gene molecular subtyping profile that discriminates between three breast cancer subtypes: Luminal, HER2, and Basal.
• TargetPrint provides a quantitative measurement of estrogen receptor (ER), progesterone receptor (PR), and HER2.
• Oncotype DX measures expression of five reference genes and 16 cancer-related genes, quantifying the risk of distant recurrence in patients with ER+ early breast cancer who are treated with adjuvant hormonal therapy.

Trial design:
PROMIS is a prospective study that will investigate the additional value of MammaPrint, BluePrint and TargetPrint in women with an intermediate Oncotype DX score. An initial CRF – capturing baseline patient characteristics, pathology information, Oncotype DX score and the recommended treatment plan – will be completed before receiving the MammaPrint result. A second CRF – capturing the actual treatment – will be completed within 4 weeks after receiving the MammaPrint result.

Eligibility: The study will include women aged ≥18 years with histologically proven invasive stage I-II, node negative or node positive (N1), hormone receptor positive, HER2 negative breast cancer, who received an Oncotype DX intermediate score (18-30) and who signed informed consent.

Objectives:
Primary objective:
Assess the impact of MammaPrint on chemotherapy + endocrine versus endocrine alone treatment decisions in lymph node negative, hormone receptor positive, HER2 negative breast cancer patients, who received an Oncotype DX intermediate score (18-30)

Secondary objectives:
• Assess the impact of MammaPrint on chemotherapy + endocrine versus endocrine alone treatment decisions in lymph node positive (N1), hormone receptor positive, HER2 negative breast cancer patients, who received an Oncotype DX intermediate score (18-30)
• Assess the distribution of MammaPrint Low and High Risk in patients with an intermediate recurrence score
• Assess concordance of TargetPrint ER, PR and HER2 results with Oncotype DX ER, PR and Her2 and with locally assessed IHC/FISH ER, PR and HER2
• Compare clinical subtype based on IHC/FISH ER, PR, HER2 and Ki-67 (if available) with BluePrint molecular subtype

Statistical methods:
A sample size of 820 lymph node negative, hormone receptor positive, HER2 negative breast cancer patients is required to detect a 20% overall treatment change (5% significance and 90% power). A McNemars test will be performed for the comparison of the two proportions treated (before and after), both expressed as a percentage.

Accrual: A total of 385 out of 820 have been enrolled from multiple institutions.

Contact information: Clinicaltrials.US@agendia.com
Clinical trial registry number: NCT01617954.
Title: ASTER 70s UNICANCER phase III trial: Can a genomic prognosticator help tailoring adjuvant systemic treatment for luminal breast carcinoma in elderly women?

Body: The benefit of adjuvant chemotherapy (CT) added to hormonal therapy (HT) compared with HT alone remains debated for women >70 with ER+ HER2- breast cancer (BC). Selection of valid indications might be improved by the use of better prognosticator. This trial compares the impact of both strategies on overall survival (OS) according to Genomic Grade (GG). Following surgery, ∼2,000 patients (Pts) will have a GG performed centrally on FFPE specimens by RT-PCR. Those with a high risk (high or equivocal GG) will be randomized to HT alone vs CT+HT. Pts with a low GG will be followed as an observational cohort.

OS (all deaths) is the primary endpoint. Secondary objectives include competing events, cost-effectiveness and Q-TWiST analysis, geriatric dimension, willingness and health-related quality of life including specific ELD15. Translational research will focus on prognostic biomarkers and pharmacogenetics.

Statistical design: sample size based on 4-year OS benefit favouring CT (87.5 vs 80%; HR 0.60); bilateral test α=0.05, β=0.20; 129 events expected in 700 randomized Pts enrolled over 4 years.

From 04/12-05/14, 67 centres in France and Belgium have included 990 Pts aged 70-92. Only 31 GG evaluations were not performed (tumour blocks not available, 14; consent withdrawal or central pathology review discordance, 7 each; treatment choice, 3). In the main recruiting site, the study was not proposed to 20% of pre-screened Pts mostly because of team choice (50%) and inclusion criteria (25%). Amongst those informed, 66% accepted to participate. Median time to get GG information was 17 days (11-25) from sending tumour sample to providing the information to patient.

Of 932 cases with GG report, 374 (40%), 187 (20%) and 362 (39%) were low, equivocal and high GG respectively; 9 tests (1%) failed for technical reasons. The proportion of high-risk tumours (high/equivocal GG 59%) is similar to that observed in general BC populations (40% to 60%) and only 21 of high-risk cases were not randomized (consent withdrawal, 6; treatment choice, 5; laboratory values, 4; tumour phenotype not confirmed or distant metastasis, 3 each).

With 75% of target recruitment in < 2 years, we confirm the feasibility of such innovative multicentre program in an usually underserved population. This might help to better select adjuvant strategy in the elderly BC population and to avoid jeopardising any benefit if stymied by uncontrolled side effects.
A randomized controlled trial comparing primary tumour resection plus systemic therapy with systemic therapy alone in metastatic breast cancer (JCOG1017 study; PRIM-BC)

Tadahiko Shien¹, Hiroji Iwata², Kenichi Nakamura³, Takayuki Kinoshita⁴, Fumikata Hara⁴, Tomomi Fujisawa⁵, Norikazu Masuda⁶, Kenichi Inoue⁷, Taro Shibata³ and Haruhiko Fukuda⁸. ¹Okayama University Hospital; ²Aichi Cancer Center Hospital, Nagoya, Japan; ³JCOG Data Center; ⁴Shikoku Cancer Center; ⁵Gunma Prefectural Cancer Center, Ota, Gunma, Japan; ⁶Osaka National Hospital; ⁷Saitama Cancer Center and ⁸National Cancer Center Hospital.

Body: A brief background discussion: The efficacy and indication of primary tumour resection for breast cancer patients with distant metastases are under debate. There were many retrospective analysis reports indicating the survival benefit of it. However, the first results of two randomized studies reported in SABCS 2013 could not demonstrate the survival benefit. Nevertheless, the results were not conclusive because the systemic therapy was not uniform (e.g. molecular target therapy) and the diagnostic procedures of metastases was different from the widely accepted guidelines.

Trial design: Our trial is being conducted to confirm the superiority, in terms of the overall survival, of surgery plus systemic therapy over systemic therapy alone in stage IV patients who are not refractory to primary systemic therapy (PST).

Eligibility criteria: The inclusion criteria for the study are as follows: untreated patients with histologically confirmed invasive breast cancer with one or more measurable distant metastatic lesions diagnosed by radiological examination.

Specific aims: All patients receive PST according to the ER and HER2 status of the primary breast cancer after the first registration. After three months, the patients without disease progression are randomized to the primary tumour resection plus systemic therapy arm or the systemic therapy alone arm. After randomization and surgery in the former arm, or after randomization in the latter arm, the same systemic therapies are continued until progression of diseases and next appropriate regimens are started after that.

Statistical methods: The primary endpoint is the overall survival, and the secondary endpoints are proportion of patients without tumour progression at the metastatic sites, yearly local recurrence-free survival, proportion of local ulcer/local bleeding, yearly primary tumour resection-free survival, adverse events of chemotherapy, operative morbidity, and serious adverse events.

Sample size for randomized patients was determined to attain at least 80% of power to detect a 6 months difference with one-sided alpha of 0.05.

Present accrual and target accrual: The patient recruitment was started in May 2011. Enrolment of 410 patients for randomization is planned over a 5-year recruitment period. More than two hundred twenty patients were already enrolled until May 2014.
Title: A prospective, randomized trial of sentinel lymph node biopsy versus no additional staging in patients with T1-T2 invasive breast cancer and negative axillary ultrasound

Natalia S Tucker1, William E Gillanders1, Timothy Eberlein1, Rebecca Aft1, Julie Margenthaler1, Feng Gao1, Catherine Appleton1, Imran Zoberi1, Ademuyiwa Foluso1 and Amy Cyr1. 1Washington University, School of Medicine, St Louis, MO.

Body: Background: The American College of Surgeons Oncology Group Z0011 prospective randomized trial demonstrated no local control or survival advantage with more extensive axillary surgery, even in the setting of known axillary disease. These results convincingly showed that axillary surgery provides little, if any, therapeutic benefit. Given that axillary surgery is not associated with local control or survival benefit, the current role of sentinel lymph node (SLNB) is limited to staging the axilla (in other words, SLNB provides staging information but is not therapeutic).

Objectives: In this randomized, controlled non-inferiority trial we aim to determine the utility of axillary ultrasound (AUS) as a pre-operative staging modality for patients with clinically node-negative invasive breast cancer with the hope that it will be a minimally invasive replacement for SLNB.

1. Primary Objective: To assess whether axillary recurrence rates for patients randomized to Arm 1 (no SLNB) is equivalent to axillary recurrence rates for patients randomized to Arm 2 (SLNB).
2. Secondary Objective: To assess disease-free survival in Arm 1 vs. Arm 2.
3. Tertiary Objective: To assess overall survival in Arm 1 vs. Arm 2.

Study Design: A randomized non-inferiority trial comparing no further axillary staging versus SLNB in women with clinical T1-T2, N0 M0 breast cancer and negative AUS. Following a negative AUS, four hundred sixty women will be randomized in a 1:1 fashion to no further axillary staging or SLNB. Subjects will be monitored for local-regional and distant recurrence per NCCN guidelines.

Eligibility Criteria: To be eligible the patient must be 18-y.o. or older; female; have tissue-diagnosis of invasive breast cancer; cT1-2N0M0 cancer; negative AUS; ECOG \( \leq 2 \); available for follow-up; candidate for SLNB. A patient is ineligible if pregnant or lactating; has concurrent invasive bilateral breast malignancies or multicentric disease or is considered a poor surgical candidate.

Statistical Methods:
Power analysis: A power analysis was performed to determine the accrual goal. The power analysis is based on axillary recurrence, our primary endpoint. We expect an axillary recurrence rate of 1% in patients undergoing SLNB. By assuming a noninferiority limit of 2% difference, our sample size will allow us 80% power at 1-sided 0.1 significance level to assure such a noninferiority.

Data analysis: Longer-term formal data analysis for the study will be performed following the intent-to-treat (ITT) principle. Demographic and clinical characteristics of the sample, as well as efficacy, complication rates and loss to follow-up will be summarized using descriptive statistics. The balance of demographic and baseline clinical characteristics between two arms will be compared using t-test, Mann-Whitney rank-sum test, or Chi-square test as appropriate. The differences in OS and DFS between treatment arms will be compared using log-rank test.
**Title:** The LORD trial: A randomized, non-inferiority trial, between active surveillance versus standard treatment in patients with low risk ductal carcinoma in situ

Lotte E Elshof¹, Konstantinos Tryfonidis², Leen Slaets², A Elise van Leeuwen-Stok³, Nicolas Dif², Victoria P Skinner¹, Claudette E Loo¹, Gonneke Warnars¹, Eveline Bleiker¹, Ruud M Pijnappel⁴, Nina Bijker²; Emiel JTh Rutgers¹ and Jelle Wesseling¹.

¹Netherlands Cancer Institute – Antoni van Leeuwenhoek, Amsterdam, Noord-Holland, Netherlands; ²European Organisation for Research and Treatment of Cancer, Brussels, Belgium; ³BOOG Study Center, Amsterdam, Noord-Holland, Netherlands; ⁴University Medical Centre, Utrecht, Netherlands and ⁵Academic Medical Center, Amsterdam, Noord-Holland, Netherlands.

**Body: Background**

The goal in treating patients with ductal carcinoma in situ (DCIS) is to prevent the development of invasive breast cancer (iBC). However, a substantial number of DCIS lesions will never form a health hazard, particularly if it concerns slow-growing, low-grade DCIS. The conventional treatment of low-grade DCIS is similar to that of early-stage iBC, i.e. breast-conserving surgery (BCS) often followed by radiotherapy (RT), or mastectomy, and possibly hormonal therapy (HT). This implies that many women might be unnecessarily going through intensive treatment resulting in a decrease in quality of life and an increase in health care costs, without any survival benefit.

**Trial Design**

LORD is a randomized, international, multicenter, phase III non-inferiority trial. Patients will be randomized between active surveillance and standard treatment according to local policy. Active surveillance comprises monitoring by annual mammography and treatment if there is progression to iBC or higher grade DCIS. Standard treatment encompasses BCS only, BCS + RT, or mastectomy, possibly followed by HT, and follow-up by annual mammography.

**Eligibility criteria**

- Women ≥49 years
- Referral to the hospital solely based on microcalcifications detected by population-based or opportunistic screening mammography
- Unilateral, pure DCIS grade I based on multiple vacuum assisted biopsies
- No prior history of iBC or DCIS

**Specific Aims**

Our aim is to investigate whether active surveillance of low-grade DCIS is as safe as the current standard treatment, and to study the effects on quality of life of these women by saving them from intensive treatment. The primary end-point is time to ipsilateral iBC (iiBC). Secondary end-points include rate of iBC at final pathology after standard treatment, radical intervention rate, and biopsy rate during follow-up. Tissue will be collected for genomic profiling and proteomics to detect iBC risk patterns in low-grade DCIS. Furthermore we aim to develop an online informational aid for clinicians and patients to facilitate the dissemination and understanding of information on low-grade DCIS and its treatment.

**Statistical Methods**

We apply a special type of non-inferiority design, where the alternative hypothesis corresponds to "minor inferiority". We assume that the iiBC-free rate in the standard arm at 5 years equals 97.6%. The hazard ratio under the null hypothesis is 3.4 and the hazard ratio under the alternative hypothesis is 2.1, corresponding to iiBC-free rates in the experimental arm of 92.0% and 95.0% respectively. With a one-sided log-rank test for non-inferiority with α=0.05 and β=0.2, 124 events are needed for which 1842 low-grade DCIS patients need to be randomized during an accrual period of 5.5 years, and the accrual period will be followed by a further follow-up period of 7.5 years.

**Present Accrual and Target accrual**

The LORD trial is endorsed by the Dutch Breast Cancer Research Group (BOOG 2014-04) and the European Organisation for Research and Treatment of Cancer (EORTC 1401). Participating sites will be identified mid-2014. Patient accrual is expected to start early 2015.
Title: Mammographic breast density and magnetic resonance (MR) imaging in women with mammographically occult breast cancer

Chun Jennifer¹, Freya Schnabel¹, Shira Schwartz¹, Jessica Billig¹, Jennifer Gillman¹ and Linda Moy¹. ¹NYU Langone Medical Center, New York, NY.

Body: Background: Recent data suggests a correlation between mammographically-occult breast cancer (MOBC) and increasing breast density. There is a dearth of information on the assessment of the amount of fibroglandular tissue (FGT) with contiguous MR images through both breasts and background parenchymal enhancement (BPE) in women with MOBC. The purpose of this study was to evaluate the relationship between mammographic breast density (BD), BPE, and FGT in women with MOBC and mammographically evident breast cancer (MEBC).

Methods: The Breast Cancer Database at our medical center was queried for all women who were newly diagnosed with breast cancer between 2010 and 2014. Variables included age, BD, BPE, FGT, tumor characteristics. Statistical analyses included Pearson’s Chi Square Tests.

Results: Out of a total of 1781 women, there were 110 (6%) with MOBC and 1671 (94%) with MEBC. The median age of the cohort was 59 years. Majority of the patients had early stage disease (72%) and invasive ductal carcinoma (61%). There was a higher proportion of women with DCIS with MEBC (22%) compared to women with MOBC (16%) and a higher proportion of invasive lobular carcinoma in women with MOBC (17%) compared to the women with MEBC (10%). Increased mammographic BD was significantly associated with mammographically occult breast cancer (p<0.001). However, BPE (p=0.29) and FGT (p=0.28) were not associated with MOBC. In the MOBC group, there was a higher proportion of women with dense breasts on mammography (74%) compared to women with dense breasts on MRI (48%).

Conclusions: For women who develop mammographically occult breast cancer, there are currently no guidelines regarding recommendations for future screening. Increased breast density reduces the sensitivity of mammography, which compromises the ability to detect meaningful findings. Our study shows that MRI may be less affected by obstacles of sensitivity that is usually associated with mammography. Our results support the use of MRI in women with dense breasts who are at higher risk of developing MOBC. By better understanding the patient population who are more likely to be diagnosed with mammographically-occult breast cancer, we can more effectively select patients who should be screened with breast MRI.

Value of breast MRI for preoperative axillary assessment of breast cancer patients

Sean C Dupont1, Judy C Boughey1, Tanya L Hoskin1, Katrina N Glazebrook1 and Tina J Hieken1. 1Mayo Clinic, Rochester, MN.

Body: Background: Many newly diagnosed breast cancer patients undergo preoperative breast MRI which includes visualization of some degree of the axilla. The impact of patient characteristics and tumor biology on the fidelity of MRI imaging of the axilla in these cases is not well-studied. We sought to examine the correlation between nodal findings on breast MRI and pathologic nodal status in newly diagnosed breast cancer patients.

Methods: With IRB approval, we identified 1868 consecutive breasts with invasive cancer in 1803 patients undergoing primary operation with axillary surgery from 1/2010-7/2013. Patients undergoing neoadjuvant chemotherapy (348) were excluded leaving 1510 breasts with cancer in 1455 patients. Preoperative MRI was performed in 763 patients (52%). We evaluated patient, imaging and pathology data.

Results: Patients evaluated with MRI were median age 57 years. The majority of tumors were T1 (63%) and T2 (28%). MRI identified suspicious axillary nodes in 240 cases (31%), of which 123 (51%) were node positive at operation. Suspicious axillary findings on MRI predicted both nodal status and pN stage at operation (both p<0.0001). The sensitivity, specificity, accuracy, positive (PPV) and negative predictive value (NPV) of MRI for nodal disease across tumor types is shown.

</table>

Diagnostic performance did not vary significantly based on patient body mass index (BMI) or approximated biologic subtype, but specificity was better for patients >age 50 (p=0.007) and sensitivity and PPV both were worse for grade 1 vs grade 2/3 tumors.

Node positivity rate at operation was 48% (51/106) for patients with a solitary abnormal node on MRI and 54% (72/134) when >1 suspicious node was seen (p=0.39). However, multiple vs solitary MRI suspicious nodes correlated with ≥3 positive nodes at operation (40 [30%] vs 19 [18%, p=0.03) and pN2/pN3 disease (29 [22%] vs 12 [11%, p=0.03).
Conclusion: Axillary lymph node findings on MRI for breast cancer predict nodal status and disease volume in invasive breast cancer patients. Tumor biologic subtype did not affect performance characteristics of preoperative MRI, but tumor grade did influence the sensitivity and PPV of MRI. When MRI is performed in the evaluation of newly diagnosed breast cancer, axillary findings inform pathologic nodal stage at operation regardless of tumor subtype.

Title: Evaluation of tumor response after neoadjuvant chemotherapy in breast cancer patients: Correlation between dynamic contrast-enhanced MRI and pathologic tumor cellularity

Hak Hee Kim, Won Kyung Kim, Joo Hee Cha, Hee Jung Shin, Eun Young Chae and Woo Jung Choi. 1Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea.

Body: Purpose: The objective of the study was to analyze whether the measurement of changes of the tumor on magnetic resonance imaging (MRI), could be applied to predict pathologic response after neoadjuvant chemotherapy.

Methods: Between January 2013 and October 2013, 155 patients (age range, 31-74 years; mean age, 47.6 years) with pathologically proven breast cancer who underwent neoadjuvant chemotherapy followed by surgery were retrospectively enrolled. Pre-and post-treatment measurements and changes in tumor size and dynamic curve pattern of MRI were analyzed. Histological regression was scored on the residual overall tumor cellularity based on Miller-Payne grading system.

Results: The change of maximal diameter (\( \rho = 0.681, p < 0.001 \)), angio-volume of tumor (\( \rho = 0.683, p < 0.001 \)) and washout ratio of dynamic curve (\( \rho = 0.607, p < 0.001 \)) measured on MRI showed strong correlation with histological regression. Among them, the correlation factor was highest in the change of angio-volume. The change of plateau ratio of dynamic curve showed moderate correlation (\( \rho = 0.574, p < 0.001 \)) with histological regression. However, the change of persistent ratio of dynamic curve showed weak correlation (\( \rho = 0.206, p = 0.011 \)).

Conclusions: The change of maximal diameter, angio-volume of tumor and washout ratio of dynamic curve measured on MRI showed strong correlation with residual cellularity in lesions after neoadjuvant chemotherapy and could be applied to predict pathologic response.
Title: Effects of preoperative MRI on rate of ipsilateral and contralateral recurrence of breast cancer

Amanda L Amin¹, Irene B Helenowski¹, Thomas E Kmiecik¹, Shruti R Zaveri¹, Nora M Hansen¹, Kevin P Bethke¹ and Seema A Khan¹. ¹Northwestern University, Chicago, IL.

Body: Introduction: Preoperative MRI of the breast is the most sensitive imaging modality in the detection of multifocal or multicentric breast cancer, as well as simultaneous contralateral breast cancer. The aim of this retrospective review was to evaluate the effect of preoperative MRI on local control for patients with breast cancer.

Methods: The Enterprise Data Warehouse of Northwestern Medicine was searched for women who underwent breast conserving surgery for ductal carcinoma in situ (DCIS) or primary invasive breast cancer in the interval of 2004-2010. The use of preoperative MRI, and the clinical and therapeutic details of the patients thus identified were extracted by direct review of the electronic medical record. A breast event was defined as a local recurrence in the treated breast more than six months after completion of treatment (ipsilateral) or a new breast cancer in the untreated breast (contralateral). Differences in the frequency of all events (local and distant), for ipsilateral breast events, and for contralateral breast events was evaluated with Cox proportional hazards model, adjusting for patient age, tumor size, nodal status, the presence of triple negative disease, and the use of radiotherapy and systemic therapy.

Results: In our cohort of 1097 patients, 526 had preoperative MRI and 571 had no MRI. The patients who had preoperative MRI were younger (59 vs. 66 years, p<0.0001), were more commonly premenopausal (37.8% vs. 27.3%, p=0.0004), were more likely to present with palpable tumors (34.8% vs. 26.6%, p=0.004), were more likely to have invasive lobular disease (16% vs. 11.6%), and less likely to have DCIS (16.5% vs. 29%, p=0.001 for differences in histologic pattern). Mean tumor size was equivalent in the two groups (17.5 and 17.3 mm), but nodes were more frequently positive in the MRI group (23.9% vs. 19.1%, p=0.045). Triple negative tumors were more frequent in the MRI group (14.1% vs. 7.5%, p=0.0003). Mean follow up was 51.5 months in the MRI group and 59.4 months in the no MRI group (p<0.0001). The number of events was 49 in the MRI group and 68 in the no MRI group. The Cox hazard ratio (HR) for all events (adjusted for follow-up duration and factors described in the Methods) was equivalent between the two groups (HR 0.90, 95% CI 0.59-1.36, p=0.61). The HR for ipsilateral (HR 0.93, 95% CI 0.57-1.51, p=0.76) and contralateral events (HR 1.22, 95% CI 0.57-2.62, p=0.61) was equivalent between the two groups.

Conclusions: In analyses adjusted for important prognostic features, the use of preoperative breast MRI was not associated with a reduced hazard of any breast cancer event, or of in-breast events (ipsilateral or contralateral). However, the MRI group had a more adverse tumor and patient profiles; a propensity score analysis will be performed, to further adjust for these differences. These findings add weight to the position that routine use of preoperative MRI for all breast cancer patients is not beneficial.
Title: Quantitative breast DCE-MRI risk biomarkers and breast tumor immunohistochemistry phenotypes: A preliminary assessment

Shandong Wu¹, Margarita L Zuley¹,², Brenda F Kurland¹, Rachel C Jankowitz¹,², Jules Sumkin¹,² and David Gur¹. ¹University of Pittsburgh, Pittsburgh, PA and ²UPMC Magee-Womens Hospital, Pittsburgh, PA.

Body: Purpose
Fibroglandular tissue (FGT) and background parenchymal enhancement (BPE) estimated from breast dynamic contrast enhanced MRI (DCE-MRI) have been correlated with breast cancer risk. We performed a preliminary study assessing in a small cohort of breast cancer patients the relationship between FGT and BPE both quantified from cancer-unaffected breasts and breast tumor’s immunohistochemistry phenotypes, including testing of estrogen (ER), progesterone (PR), and human epidermal growth factor receptor 2 (HER-2/neu) receptors.

Materials and Methods
We retrospectively identified 51 breast cancer patients who were diagnosed with unilateral breast cancer from 2009-2011. Six out of the 51 were excluded for analysis due to missing data in ER, PR, or Her-2 testing in their pathology reports. The 45 cancer patients (mean 47.3±7.6 YO; 24 IDC, 4 ILC, 16 mixed of IDC and DCIS, and 1 papillary carcinoma) consist of 25 premenopausal and 20 postmenopausal women. Breast DCE-MRI scans acquired at time-of-diagnosis were analyzed using fully automated computer algorithms. From the contralateral cancer-free breast, four quantitative variables were computed for each patient: the absolute volumes of FGT and BPE (i.e., |FGT| and |BPE|) and their relative amount over the whole-breast volume (i.e., FGT% and BPE%). BPE were assessed over the FGT region of the breast, and separately from each of the three sequential DCE post-contrast-subtracted sequences (i.e., SUB1, SUB2, and SUB3). Multivariable logistic regressions were performed to assess the quantitative FGT/BPE variables for distinguishing/predicting the status (+/-) of ER, PR, and HER-2 testing. Area under the curve (AUC) of the receiver operating characteristic (ROC) was used to evaluate the regression models’ discriminative performance. Odds ratios (ORs) were reported with 95% confidence intervals (CIs).

Results
In this cohort, the most common phenotypes were ER+/PR+ (14/45 each HER2+ and HER2-) and triple negative (9/45). Premenopausal status was associated with tumors that were HER-2+ (AUC=0.66; p=0.04), ER+ (AUC=0.73; p=0.02), and PR+ (ACU=0.66; p=0.04). FGT% (AUC=0.74; p=0.017; OR=5.3 [95% CI: 1.3, 21.1]) and BPE%-SUB3 (AUC=0.69; p=0.02; OR = 1.4 [95%CI: 1.1, 1.9]) were discriminative of HER-2 status; after adjusting for menopausal status, FGT% remained the association (AUC=0.77; p=0.04; OR=4.4 [95% CI: 1.1, 18.5]) but BPE%-SUB3 did not (p=0.06). BPE%-SUB1 was discriminative of PR status (AUC=0.70; p=0.03; OR=2.3 [95%CI: 1.1, 4.8]) but did not contribute to predict when adjusting for menopausal status (AUC=0.75; p=0.06). All FGT and BPE variables were not associated (p>0.05) with ER status.

Conclusions
In this preliminary study, FGT% and BPE% were associated with HER-2 and PR status, and none of FGT and BPE was associated with ER status, of breast tumor.

Clinical Relevance
Quantitative MRI variables of FGT and BPE that are predictive of breast cancer risk are related to breast tumor immunohistochemistry phenotypes. While FGT and BPE cannot replace the testing of these phenotypes, they may contribute to assess the risk of molecular subtypes of breast cancer, with potential implications for improving breast cancer screening strategies.
Title: Quantitative assessment of early- and delayed DCE-MRI background parenchymal enhancement in breast cancer risk prediction

Shandong Wu¹, Wendie A Berg¹,², Margarita L Zuley¹,², Brenda F Kurland¹, Rachel C Jankowitz¹,², Jules Sumkin¹,², Robert M Nishikawa³ and David Gur¹. ¹University of Pittsburgh, Pittsburgh, PA and ²UPMC Magee-Womens Hospital, Pittsburgh, PA.

Body: Purpose

Background parenchymal enhancement (BPE) estimated from breast dynamic contrast enhanced MRI (DCE-MRI) has been correlated with breast cancer risk. Multiple time-point post-contrast-subtracted sequences are acquired in typical clinical breast DCE-MRI protocols. We quantitatively assessed BPE using fully automated computer algorithms and investigated the relationship between BPE quantified from three time-point post-contrast sequences and breast cancer risk prediction.

Materials and Methods

A retrospective case-control study was performed using breast DCE-MRI scans from 102 patients (mean 47.2±7.3 YO) who underwent either open surgical biopsy or core biopsy from 2009-2011: 51 women had unilateral breast cancer and 51 were age- and date-of-MRI matched controls with a unilateral biopsy-proven benign. For each MRI scan, three post-contrast-subtracted sequences (i.e., SUB 1, SUB 2 and SUB 3) acquired over a total of 7 minutes were analyzed. BPE was quantified from each of the sequences using fully automated computer algorithms on the breasts contralateral to the cancers and the contralateral (negative) breasts of the controls. For each sequence, two quantitative BPE measures were generated: the absolute BPE volume (|BPE|) and its relative amount over the whole breast volume (BPE%). Volumetric absolute and relative amounts of fibroglandular tissue (|FGT| and FGT%) were also automatically quantified, from the pre-contrast sequence. BI-RADS breast density assessment was retrieved from the mammography report (< 6 months) prior to cancer diagnosis (for cases) or MRI (for controls). Multivariable conditional logistic regression was performed to assess BPE measures, quantified respectively from SUB 1, SUB 2, and SUB 3, as predictors of breast cancer risk.

Results

Breast cancer risk odds ratios (ORs) were reported by |BPE| and BPE% (Table 1), after adjustment for breast density, |FGT|, and FGT%. Breast density did not correlate with risk for breast cancer in this study cohort: OR for BI-RADS density alone was 0.75 (95% CI: 0.35, 1.59; p=0.5). OR was 1.14 (95% CI: 0.72, 1.81; p=0.6) for |FGT| alone and 0.70 (95% CI: 0.19, 2.52; p=0.6) for FGT% alone.

Table 1: Breast cancer risk odds ratios (ORs) with 95% confidence intervals [CIs] for BPE quantified from SUB 1, SUB 2, and SUB 3, respectively.

</tbody>
</table>

Conclusions

Increased BPE quantified from DCE-MRI are predictive of breast cancer risk, independent of measures of breast density and FGT. BPE estimated from three time-point SUB sequences has a similar predictive effect of breast cancer risk, while an early sequence (e.g., SUB 1) appears to have a larger magnitude of effect than that of a delayed sequence (e.g., SUB 3).

Clinical Relevance

Quantified BPE in breast DCE-MRI has potential for use as a biomarker of breast cancer risk and may be included to improve breast cancer risk prediction. A single post-contrast sequence (i.e., SUB 1) may be adequate for use to estimate breast cancer risk using breast MRI in the context of breast cancer screening for high-risk women.
Title: Changes in breast density with mammography and breast MRI among high-risk postmenopausal women

Parijatham S Thomas, Mary Beth Terry, Xiaotao Guo, Binsheng Zhao, Richard Ha, Swathi Namburi, Tong Xiao, Dawn Hershman, Susan Refice and Katherine D Crew. Columbia University Medical Center, New York, NY.

Body: Background: Mammographic density (MD) represents one of the strongest predictors of breast cancer risk. Tamoxifen, a selective estrogen receptor modulator (SERM) and proven chemopreventive agent, causes reductions in MD which correlate with subsequent breast cancer risk. Current methods for measuring MD, such as the Cumulus technique, are labor intensive and not fully automated, which limits utility in the clinical setting. Breast MRI is being used with increasing frequency in high-risk women for breast cancer screening and yields 3-dimensional views of breast volume. Breast MRI fibroglandular tissue volume (MRIV) has been correlated with MD in cross-sectional studies, but less is known about changes in breast density over time on MRI and its relation to breast cancer risk. One study reported a significant reduction in breast MRIV but not MD with the SERM, raloxifene, in high-risk women. We implemented a novel MRI segmentation method to measure MRIV compared to MD in 20 high-risk postmenopausal women that received high-dose vitamin D supplementation for 1 year.

Methods: Twenty high-risk postmenopausal women [defined as a 5-year breast cancer risk per the Gail model of ≥1.67%, lobular or ductal carcinoma in situ (LCIS/DCIS)] were assigned to a 1-year intervention of vitamin D3 20,000 IU or 30,000 IU weekly. Other eligibility criteria included baseline MD ≥25% (as assessed qualitatively by BIRADS category) and no current SERM use. Women underwent a digital mammogram and breast MRI at baseline and 12 months. MD was evaluated by the Cumulus technique and MRIV was measured using a novel segmentation method on noncontrast T1-weighted images from breast MRIs. The method incorporated two well-established image analysis techniques, the region-based active contour model and watershed algorithm, into a unified framework. Specific anatomical landmarks were introduced into the algorithm to consistently identify breast boundaries on longitudinal MRI slices. For fibroglandular tissue segmentation, an algorithm combining region-based active contours and level-set approach was used to allow for easy initialization and fast speed. Correlation coefficients and paired t-tests were used to compare MD and MRIV and changes from baseline to 12 months.

Results: From Nov 2007 to Jan 2011, 20 postmenopausal women were enrolled and 16 were evaluable at 12 months. Mean baseline breast density measurements were lower for MD compared to MRIV, 12.89% (SD 11.99) vs. 26.64% (SD 6.95), respectively. After 1 year of high-dose vitamin D, there was no significant change in MD or MRIV, mean absolute changes of -0.14% vs. -1.12%, respectively. We did not observe a significant correlation between MD and MRIV density measurements (correlation coefficient= -0.31, p=0.08).

Discussion: We observed greater changes over time in breast density on serial breast MRI compared to mammography, however, no significant changes in MD or MRIV was noted after a 1-year intervention of vitamin D. Longer follow-up may be required in order to detect changes in breast density with non-hormonal interventions.
**Title:** Optimization of magnetic resonance imaging predictive performance by breast cancer subtypes for predicting response to neoadjuvant chemotherapy

Wen Li¹, Wei-Ching Lo¹, Ella F Jones¹, David C Newitt¹, John Kornak², Lisa J Wilmes¹ and Nola M Hylton¹. ¹University of California San Francisco (UCSF), San Francisco, CA and ²UCSF, San Francisco, CA.

**Body:**

**Objective:** Change in functional tumor volume (FTV) measured by dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI), has been shown to be associated with response to neoadjuvant chemotherapy (NACT) for patients with stage II/III breast cancer. FTV reflects the vascularized volume of tumor and is calculated by applying minimum thresholds PE for the initial percent enhancement and SER for the early-to-late signal enhancement ratio following gadolinium contrast injection. In this retrospective study, we investigate the association of FTV influenced by PE and SER values with recurrence-free survival (RFS) in breast cancer subtypes defined by hormone receptor (HR) and HER2 status.

**Materials and Methods:** 64 patients with locally advanced breast cancer were imaged by DCE-MRI before treatment (MRI₁), after one cycle of adriamycin-cytoxan (AC) therapy (MRI₂), inter-regimen (MRI₃, taxane receivers only) and at the completion of chemotherapy prior to surgery (MRI₄). Because treatment length and regimen varied among patients, the MRI exam performed after all NACT and before surgery was designated as final MRI (MRI₅). FTV was calculated with varying PE (30–200% in steps of 10%) and SER (0–2 in steps of 0.2) values. A Cox proportional hazard model was used to analyze association with RFS, defined as the time between surgery and disease recurrence or last disease-free follow-up, for the following imaging predictors: early percent change in FTV (ΔFTV₂: MRI₁ vs. MRI₂), final percent change (ΔFTV₅: MRI₁ vs. MRI₅), and final FTV in MRI₅ (FTV₅). RFS association was evaluated for the full cohort and within subsets defined by tumor subtype (HR+/HER2-, HER2+, triple negative). Estimated hazard ratios per unit change in predictors, associated 95% confidence intervals (CI) and p-values were evaluated. The cutoff of p<0.05 was used to differentiate PE/SER values with higher predictive performance.

**Results:** For the full cohort, FTV₅ showed the most robust association with RFS among the three predictors, with p<0.05 across all measured combinations of PE/SER. The PE/SER combination with smallest p-value was found for PE=30% and SER=0.2, with hazard ratio 1.09 (95% CI 1.06–1.13, p<0.001). P-values less than 0.05 for the ΔFTV₂ predictor was found for the full range of SER values tested, but was mostly confined to PE in 30–110% range; ΔFTV₂ resulted in p<0.05 for very few PE/SER combinations. When analyzed by tumor subtypes, different prediction profiles were observed. FTV₂ showed p<0.05 for the lower PE range only in the HER2+ (n=15) and triple-negative (n=11) groups. A limited number of PE/SER pairs showed p<0.05 for ΔFTV₂, with the exception of the ΔFTV₂ in the triple-negative group, for which p <0.05 for many PE/SER combinations in the low PE range. **Conclusions:** This study was undertaken to explore the significance of FTV for predicting breast cancer recurrence following NACT. While this study is retrospective in nature and had small sample size, the findings nevertheless suggest that performance of imaging predictors based on FTV may be improved if threshold optimization is performed separately for the clinically-relevant subtypes defined by HR and HER2 receptor expression.
Title: A preoperative PET/MR imaging for diagnosing malignant axillary lymph nodes in women evaluated for breast cancer

Kyung Jun Yeu¹, Jeong Yeong Park¹, Jung Eun Choi¹, Su Hwan Kang¹, Eun-Jung Kong², Ihn-Ho Cho² and Soo Jung Lee¹. ¹Yeungnam University College of Medicine, Daegu, Korea and ²Yeungnam University College of Medicine, Daegu, Korea.

Body: Objective: We determined whether and how malignant node could be diagnosed preoperatively with simultaneous PET/MR imaging.

Materials and methods: Two hundred thirty-six consecutive women with breast cancer were recruited to undergo preoperative PET/MR imaging. 52 patients were excluded; 31 DCIS, 7 neoadjuvant chemotherapy and 14 previous excisional biopsy. Thus, 184 women (51.9 ±10.2 years old) were included. Axial T1w without fat saturation, contrast enhanced image and diffusion-weighted images with simultaneous acquired PET images were analyzed by nuclear medicine physicians who were blinded the histologic findings. Visual FDG avidity, long axis and cortical thickness of axillary lymph node (ALN), morphologic feature-loss of fat hilum, cortical thickening, round shape or irregular shape- and ADC value were analyzed in most suspicious ALNs.

Results: In total, 70 patients (15 patients have only micrometastasis) exhibited ALN metastasis. Mean size of breast mass was 2.1 ±1.5 cm. Macrometastatic ALN showed high FDG uptake, longer axis, thicker cortex, more frequent morphologic abnormalities, higher signal intensity at DWI and higher ADC values with statistical significance. No significant difference between micrometastatic ALN and benign ALN in PET/MR imaging. With pathologic diagnosis as the reference standard, the sensitivity, specificity and accuracy of PET for determining ALN metastasis were 84%, 58% and 68%, respectively. Those are 77%, 84% and 82% in considering both PET with morphologic change and 81%, 66% and 72% in considering PET, morphologic change and DWI, respectively.

Conclusion: PET/MR imaging techniques showed high accuracy in the preoperative evaluation of axillary status in patients with breast cancer. Additional information by DWI is unlikely to be useful in predicting metastatic ALN.
Title: The impact of a critical look at the consequences of preoperative MRI in breast cancer patients

I Ching Yeung1, Mehrzad Namazi2, Valerie Deslauriers1, Fatima Haggar2 and Angel Arnaout1,2. 1Ottawa Hospital, Ottawa, ON, Canada and 2Ottawa Hospital Research Institute, Ottawa, ON, Canada.

Body: BACKGROUND: Despite the fact that routine use of preoperative breast MRI for breast cancer has not been shown to improve oncologic outcomes, it is still an exceedingly popular test. Due to low MRI specificity, patients may be subjected to additional invasive test. There have been few studies specifically evaluating the outcomes from these additional tests and its implications on the health care system. The objective of this study was to critically evaluate the impact of performing a preoperative MRI on breast cancer patients at our institution.

METHODS: A retrospective chart review was performed on all female breast cancer patients diagnosed and awaiting surgery (2010-2012). Based on extracted data, indications for preoperative breast MRI were established for our institution (2013). Adherence to these guidelines was then assessed over the next year.

RESULTS: In 2010-2012, 1159/1674 breast cancer patients underwent a preoperative breast MRI. The MRI group was younger (p<0.0001), but not different in histologic subtype (p=0.06) or biomarker status (p=0.61). 421/1159 (36%) of MRI patients underwent at least one additional MRI induced imaging test (ultrasound, mammogram, 6 month MRI) following the MRI. 35% (415/1159) of patients underwent an additional MRI-induced biopsies, 52% of which were benign in the breast and 62% of which were benign in the axilla. Post-MRI biopsies resulted in upstaging (DCIS to invasive cancer; node negative to node positive) in 25/1159 (2%) of patients.

Preliminary data assessing local guideline adherence demonstrated that 188/349 (54%) of new breast cancer patients underwent a preoperative MRI. Locally accepted indications for MRI use included: dense breast (26%); assessment of tumor extent; (19%); lobular carcinoma (16%); assessment of locally advanced cancer (16%). 71% of MRI studies were ordered by the radiologist. 22% of patients had no obvious indication for MRI according to our local guidelines. MRI-induced biopsies occurred in 76/189 (40.2%) of patients, 60% of which were benign in the breast and 71% of which were benign in the axilla.

CONCLUSION: We have critically evaluated the impact of preoperative breast MRI on a large volume of patients. Often, MRI results did not result in significant treatment change. Barriers to guideline evidence based care implementation continue to exist in the setting of multidisciplinary breast cancer care. We must continue to work together to best counsel our patients and effectively manage our health care cost, in keeping with the Choosing Wisely Campaign Canada.
Title: Preoperative breast MRI does not affect survival outcomes in T1-2 breast cancer patients who underwent breast-conserving therapy

Jegyu Ryu¹, Sanghwa Kim¹, Jee Ye Kim¹, Hyung Seok Park¹, Seho Park¹ and Seung il Kim¹. ¹Yonsei University College of Medicine, Seoul, Korea.

Body: Purpose: The aim of the study is to evaluate the efficacy of preoperative breast MRI in T1-2 women with breast cancer. Methods: Total 1179 patients, who had T1-2 breast cancer and underwent definitive surgery between 2007 and 2010, were reviewed in this study. Preoperative breast MRI was performed in 981 women with breast cancer. We divided patients into two groups: Patients underwent preoperative MRI and breast-conserving therapy (BCT), those who did not undergo preoperative MRI but BCT. Patients underwent preoperative MRI and total mastectomy were excluded. Clinicopathological features were analyzed using Chi-square or Fisher's exact test if indicated. Survival analyses were examined using Kaplan-Meier method and log-rank test. Cox-proportional hazard model was accessed as multivariate analysis.

Results: In 873 patients who underwent BCT, 675 patients (77.3%) received preoperative MRI, and 198 (22.7%) patients did not. Clinicopathological features including T-stage, Nodal status, histologic type, progesterone receptor, histologic grade, age group (≤ 35 vs. > 35 yr), adjuvant chemotherapy, radiation, and hormone therapy were not significantly different between two groups. Patients aged 50 or younger received more preoperative MRI than those over aged 50 years (42.8 % vs. 51.5%, p=0.02). Estrogen receptor positive-tumors were more common in patients with preoperative MRI (74.9% vs. 67.2%, p=0.03). HER2 over-expression was frequently found in women without preoperative MRI (7.9% vs. 14.6%, p<0.001). In univariate analyses, there was no significant difference in recurrence-free and overall survival between patients who underwent breast MRI and those who did not (p for RFS = 0.75, p for OS = 0.48). In multivariate analyses, preoperative MRI did not influence on RFS and OS (HR for RFS = 0.82, 95%CI= 0.35-1.91, HR for OS = 1.52, 95% CI= 0.40-5.76). Age group and HER2 were not associated with RFS and OS (all p>0.05). ER was an independent prognostic factor for RFS and OS (all p<0.01).

Conclusions: Routine use of preoperative MRI in women with T1-2 breast cancer may not translate into better RFS and OS.
Title: Evaluation of second-generation photoacoustic mammography in detecting the breast cancer vasculature and hypoxic status; a preliminary study

Masahiro Kawashima¹, Iku Yamaga¹, Masae Torii¹, Mariko Tokiwa¹, Fakhrejahani Elham¹, Masako Kataoka¹, Shotaro Kanao¹, Masahiro Takada¹, Yasufumi Asao¹, Tsuyoshi Shiina¹ and Masakazu Toi¹. ¹Kyoto University, Kyoto, Japan and ²Canon Inc, Tokyo, Japan.

Body: Background: Functional imaging of tumor vasculature and oxygenation status is essential for monitoring the therapeutic response to the manipulation of abnormal vasculature. Moreover, it could be also applicable for the detection and risk assessment of breast lesion with borderline malignancy since hypoxia and angiogenesis is known to be associated with the malignant potential of precursor lesion of solid tumor. Photoacoustic mammography (PAM) is a novel optical imaging technology that can visualize the hemoglobin distribution and its oxygen saturation (SO2) noninvasively. We have previously reported a promising clinical result of a prototype model of PAM (Canon Inc., Tokyo, Japan) in breast cancer patients. However, the improvement of spatial resolution and the identification of signal origin are still big challenges when considering its application for clinical settings.

Materials and methods: We developed the second-generation model of PAM (PAM-02). This instrument has achieved the improved spatial resolution (1.3mm) and enhanced detectability by carrying a high-sensitive detector. Moreover, it is equipped with B-mode ultrasound, which enables us to identify the tumor location in PAM images more precisely. The distribution of hemoglobin within breast tissue carrying solid tumor was evaluated by using PAM-02 under the approval of the ethics committee in Kyoto University Hospital, Japan. Contralateral breast without tumor was also evaluated as a control if possible. Calculated SO2 from photoacoustic (PA) signals were illustrated by using color scale.

Results: Seventeen breast lesions from 15 patients were analyzed including 4 ductal carcinoma in situ (DCIS), 12 invasive ductal carcinoma (IDC) and one usual ductal hyperplasia. Tumor locations were successfully identified in 14 out of 17 lesions (82.3%) by B-mode ultrasound imaging. The location of 3 lesions undetectable by B-mode ultrasound imaging could be identified by comparing with corresponding MRI images. B-mode ultrasound imaging made it easy to distinguish intra-tumoral PA signals from peri-tumoral PA signals. Intra-tumoral PA signals were detectable in 68.7% of malignant lesions (11 out of 16 lesions). Peri-tumoral PA signals, which were suggested to be from feeding vessels, were detectable in 81.3% of malignant lesion (13 out of 16 lesions). In the case of benign UDH, PA signals were not detected in either intra- or peri-tumoral region. Intra-tumoral SO2 was estimated to be lower than peri-tumoral SO2 in malignant lesion. While peri-tumoral PA signals were often described as continuous vasculature, intra-tumoral PA signals often showed the spotty patterns. In addition, PA signal density was relatively higher in DCIS compared with IDC. These findings was supposed to reflect the decreased hemoglobin perfusion within solid structure of breast cancer. The minimum detectable lesion was DCIS with a diameter of 8mm.

Conclusion: Improved spatial resolution and combination with B-mode ultrasound imaging facilitate the region-specific evaluation of PAM imaging. PAM-02 was supposed to be feasible for evaluating the hypoxic status within small breast tumor and its microenvironment.
Title: Locoregional assessment by FDG PET/CT in stage II/III breast cancer patients: A multivariate analysis

Suzana C Teixeira¹, Bas B Koolen¹, Wouter V Vogel¹, Marcel P Stokkel¹, Marie-Jeanne Vrancken-Peeters¹, Vincent van der Noort¹, Emiel J Th Rutgers¹ and Renato A Valdés-Olmos¹. ¹Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands; ²Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands; ³Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands; ⁴Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands; ⁵Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands; ⁶Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands and ⁷Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands.

Body: Aim: Previously we demonstrated the additional value of PET/CT in prone position for breast cancer detection. The purpose of the present study was to evaluate, with a multivariate analysis, the factors influencing detection and quantification of FDG–avid primary tumors (PT) and regional lymph node metastases (LN) detected with PET/CT in patients with stage II/III breast cancer.

Materials and methods: From August 2010 to April 2012 we included 198 patients (mean 51 yr, range 26–82), with stage II/III breast cancer. A dose of 18F–FDG between 180–240 MBq, was administered intravenously. After 60±10 minutes a PET/CT of the thorax in prone position was acquired, scanning 3.00 min per bed position and reconstructed in high–resolution using 2x2x2 mm voxels and 2 mm CT slice thickness. Subsequently, a standard PET/CT was performed in supine position from skull base to thighs, scanning 1.30 min per bed position and using a standard reconstruction with 4x4x4 mm voxels, a standard 5mm CT slice reconstruction and an extra 2 mm CT slice reconstruction. On all PET/CT images we quantitatively assessed the SUVmax of FDG–avid PTs and LNs. We qualitatively assessed tumor multifocality, PT visibility, LN detection in defined regions and the occurrence of anatomical mismatch between PET and CT. The obtained results were then evaluated with a multivariate analysis for scanning position, patient age, breast size, tumor volume, number of FDG–avid lesions, lymph node location and anatomical mismatch between PET and CT.

Results: Prone position imaging positively influenced the visualization of tumor multifocality (p<0.001), the total number of lymph nodes (p<0.001) and of axillary LNs (p<0.001). PT visibility was not significantly influenced by any of the parameters.

A higher SUVmax of the primary tumor was found solely with increased tumor volume (p=0.001) or breast size (p<0.001). The standard 5mm CT slice reconstruction of the supine PET/CT was the only factor causing an increase in anatomical mismatch between PET and CT for axillary lymph nodes (p=0.004).

Conclusion: Prone position for PET/CT influences the visualization of primary tumor multifocality and the number of FDG avid loco-regional lymph nodes. Tumor FDG-uptake appears to be most influenced by tumor volume and breast size. Both results can be important for adequate staging and subsequent breast cancer treatment.
Title: The effect on short-term progression free survival of the detection of ≥4 FDG-avid nodes or occult N3–disease in breast cancer patients with PET/CT

Suzana C Teixeira1, Bas B Koolen1, Paula HM Elkhuizen1, Vincent van der Noort1, Marie-Jeanne Vrancken-Peeters1, Marcel P Stokkel1, Emiel J Th Rutgers1 and Renato A Valdés-Olmos1. 1Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands; 2Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands; 3Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands; 4Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands; 5Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands; 6Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands; 7Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands and 8Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands.

Body: Aim: The risk for locoregional recurrence (LRR), after neoadjuvant chemotherapy (NAC), is based on staging before NAC as well as the final pathology after NAC. Especially the number of tumour-positive axillary nodes, which is also an important selection factor for postoperative radiotherapy, is not adequately assessed by ultrasound before NAC or axillary lymph node dissection after NAC. PET/CT has a high positive predictive value for the detection of lymph node metastases. Newly found lymph node metastasis on PET/CT incentivized us to change the radiotherapy plan for patients with primary breast cancer scheduled for NAC in our institute.

Koolen et al. reported an upstaging of 23% stage II–III breast cancer patients to the radiotherapy requiring high-risk group (≥4 FDG-avid axillary nodes or detection of occult N3–disease) due to new lymph node metastasis detected with FDG PET/CT imaging. In this study, we report the effect of this upstaging with PET/CT short-term progression free survival (PFS).

Materials and methods:
Between 2007 and 2011 a total of 278 breast cancer patients (mean age 48.9y, range 19–75y), with a tumour of at least 3 cm and without metastases, received a baseline PET/CT for staging purposes and subsequent response monitoring to NAC. The group was divided in three groups: a low-(T2N0), intermediate- (T0–2N1 and T3N0) and a high-risk group (T0–3N2–3, T3N1 and T4). We classified LRR, distant metastases and death as an "event"; including all patients in the PFS analysis of the first 3 years.

Results:
With a median follow-up (FU) of 37 months and the upstaging as depicted in table 1

Table 1: The group was divided in three groups: a low- (T2N0), intermediate- (T0–2N1 and T3N0) and a high-risk group (T0–3N2–3, T3N1 and T4). The table shows the upstaging of breast cancer patients from low- and intermediate- to the high-risk group, and thus, after PET/CT, requiring radiotherapy.

: The patients not upstaged by PET/CT showed no difference in PFS between the high-risk, intermediate-risk and low-risk groups (Logrank p=0.18). Due to the migration of the 43 patients from the low- and intermediate group to the high-risk group, based on PET/CT findings, the PFS differed significantly between the risk-groups (Logrank p=0.04). No difference in loco-regional recurrence was seen between the low-risk and the high-risk group (P=0.18).

Conclusion:
After upstaging with PET/CT, into the high-risk group requiring radiotherapy, a significant difference is seen between the three risk-groups. PET/CT restaging may more adequately predict progression free survival. The detection occult lymphatic metastasis with PET/CT leads to upstaging in clinically unsuspected patients with primary breast cancer, enabling adequate radiotherapy treatment.
Impact of perflubutane-enhanced ultrasonography for evaluating malignancy grade of breast cancer

Noriko Yoshimura¹, Norio Masumoto¹, Ai Amioka¹, Keiko Kajitani¹, Hideo Shigematsu¹, Akiko Emi¹, Takayuki Kadoya¹, Tsuyoshi Kataoka¹, Rumi Haruta¹ and Morihito Okada¹. ¹Hiroshima University, Horoshima, Japan.

Body: Objectives
This study aimed to determine whether or not signal intensity caused by the contrast effects of Contrast-enhanced ultrasonography (CEUS) using perflubutane could predict malignancy grades of invasive breast cancer.

Methods
Fifty-four patients with clinical stages I – III breast cancer between April 2013 and April 2014 underwent CEUS using perflubutane. We analyzed the association between contrast-effect intensity and contrast time in CEUS and the prognostic factors based on tumor size, nodal status and immunohistochemical markers (ER, HER-2 status, nuclear grade, Ki-67) in breast cancer.

Results
Time to washout of time required to reach plateau intensity from the start of the maximum intensity was significantly associated with the Ki-67 value (p = 0.03). Also, A parameter of intratumoral blood perfusion, peak intensity (PI), was significantly associated with the Ki-67 value (p = 0.006) and ER status (p = 0.002) (Table 1), but not with tumor size (cT; p = 0.25, pT; 0.96), node status (p = 0.99), HER-2 status (p = 0.32) and nuclear grade (p = 0.61).

Also, Thirty-eight, 7, and 9 patients had luminal, HER-2-positive and triple-negative tumors, respectively. The PI values for these tumors were 56.8 ± 20.9, 71.9 ± 20.5, and 85.7 ± 23.2, respectively. And, the PI value was significantly greater in the triple-negative, than in luminal tumors (p = 0.001).

Furthermore, PI significantly correlated with the Ki-67 value (Spearman r = 0.54, P = 0.00002).

**Conclusions**

These findings indicated that PI has excellent predictive value for grade malignancy in breast cancer and might help to determine appropriate therapeutic strategies.

**Key points**

- Contrast-enhanced ultrasonography (CEUS) enables the real-time evaluation of detailed hemodynamics in breast cancer.
- Peak intensity (PI) was significantly associated with Estrogen Receptors and Ki-67 assessed by immunohistochemistry.
- PI significantly correlated with the Ki-67 value, indicating that PI reflects the grade of proliferative activity in tumors.
- Analyses of contrast-effect intensity will be applied to evaluate grades of malignancy and determine treatment strategies.
Title: An analysis of lesions diagnosed on screening breast ultrasound in women with dense breasts: Four years of data

Jean M Weigert¹, ¹Hospitals of Central Connecticut, New Britain, CT and ²Mandell and Blau MD's PC, New Britain, CT.

Body: Objective: To analyze the type of cancers and high risk lesions diagnosed in women with normal mammograms with dense breasts with the addition of bilateral breast ultrasound and determine whether these lesions make an impact on clinical outcomes. Methods: Four years of ultrasound data from two sites with five offices in Connecticut was analyzed. The type of lesion including size, nuclear and histologic grade, ER/PR/Her2 status, node status, patient age and risk factors was reviewed. Results: A total of 532 Ultrasounds with Birads 4 or 5 were reported with 46 cancers or high risk lesions. There were 14 Invasive Ductal Carcinoma, 10 Invasive Lobular Carcinoma, 8 Mixed type, 1 Mucinous, 1 Tubular, 6 Ductal carcinoma in situ, 3 Atypical Ductal Hyperplasia with papilloma and 3 Lobular Carcinoma in situ. Of the invasive cancers and DCIS, 9 were nuclear grade 1, 25 nuclear grade 2 and 7 nuclear grade 3. They ranged in size from .3 to 8 .0 cm and the patient age was 45-77 years. Four patients had positive metastatic lymph nodes. 3 were in tumors that were nuclear grade 3 and one with micro metastasis was in a nuclear grade 2 tumor. 29 cancers had known hormonal status of which 27 were ER/PR+ and 2 were ER+/ PR-. 5 patents had a family history of breast cancer and 2 patients had prior history of their own breast cancer, one had uterine cancer. In the third and fourth year of screening usg, 4 cancers were diagnosed in patients who had a negative usg either one year or two years prior. They ranged in size from .4 to 1.2 cm and were all node negative.

Discussion: In our first four years of tracking patients with dense breasts, the addition of bilateral breast ultrasound diagnosed a variety of cancers and high risk lesions. These were not visible on screening mammography and were not palpable. There were 4 with node positive disease diagnosed in high nuclear grade tumors. Most patients had no additional risk factors other than dense breasts. In the third and fourth year, cancers were found in patients who had a prior screening usg. Their mammograms remained negative. The cancers were small and node negative.

Conclusion: The successful treatment of breast cancer is based on several variables including type of cancer, grade, size at diagnosis, and stage at diagnosis. We do not know at what point these lesions diagnosed with screening breast usg would have

been clinically evident, either on mammography or physical examination. One might consider that the treatment outcome would be altered if the lesions were larger and with more positive lymph nodes.
Title: Retrospective comparison of sensitivity and positive predictive value (PPV) of contrast enhanced spectral mammography (CESM) to contrast enhanced breast MRI (BMRI) in 50 malignant breasts

Luna Li¹, Lydia Liao¹, Pauline Germaine¹, Elizabeth Tinney¹, Kristin Brill² and Karen Hendershott². ¹Cooper University Hospital Women's Imaging, Voorhees, NJ.

Body: Objective: Contrast enhanced spectral mammography (CESM) is a new study using contrast for early breast cancer detection. It utilizes dual energy digital mammographic technology to detect contrast enhanced cancer that may be invisible on conventional mammogram. Limited studies have shown that adding CESM to diagnostic workup adjunct with mammogram and breast ultrasound does increase sensitivity for breast cancer detection. More studies are needed to compare the sensitivity and positive predictive value (PPV) of CESM to BMRI to further define the role of CESM in breast cancer diagnosis.

Methods: This study involved 50 malignant breasts in 48 women retrospectively chosen from of 960 patients in our institution during the period of October 2012 to March 2014. Both CESM and BMRI were done for each patient within 30 days. The cancer diagnoses were confirmed by tissue diagnoses. The number of malignant lesions was quantified in each breast. The size of lesions was classified into three categories based on standard of breast cancer stages: 1 (0.2cm - <= 2cm), 2 (2cm<lesion<=5cm), 3(>5cm). The enhancement intensity of both lesions and background has been quantified based on a scale of 0-3. Statistical significance was analyzed using T test for mean size of index cancer and mean score of enhancement intensity of background and lesions on CESM and BMRI. Sensitivity and PPV were calculated for both CESM and BMRI. Morphology consistence was calculated on both studies.

Results: Both CESM and BMRI have sensitivity of 100% for breast cancer detection. CESM has a PPV of 98% versus 93% for BMRI. No statistical significance was identified on mean size of index cancer (3.7cm for CESM and 3.8cm for BMRI). The enhancement intensity of background and lesions is significantly higher on CESM than on BMRI (p<0.01). The smallest cancer can be detected by both CESM and BMRI is less than 0.5 cm. Morphology consistence was 46/50 (92%). Of the 50 breasts, there was one false-positive finding at CESM mammography, and four false-positive findings at MR imaging.

Conclusions: Our study indicates that CESM and BMRI have comparable high sensitivity on breast cancer detection. CESM has a higher PPV than BMRI that may indicate a better specificity (no significant difference due to the small sample size). Significantly less background enhancement intensity on CESM than on BMRI reflect an increased specificity. More studies need to be conducted for further evaluation.
Title: Contrast-enhanced ultrasound for evaluation of therapeutic efficacy of radiofrequency ablation for primary breast cancer

Toshikazu Ito¹, Jyunji Okayama¹, Kumiko Uji¹ and Masaaki Izukura¹. ¹Rinku General Medical Center, Osaka, Izumisano, Japan; ²Rinku General Medical Center, Osaka, Izumisano, Japan; ³Rinku General Medical Center, Osaka, Izumisano, Japan and ⁴Rinku General Medical Center, Osaka, Izumisano, Japan.

Body:
To evaluate therapeutic efficacy of percutaneous ultrasound (US) guided radiofrequency (RF) ablation therapy for primary breast cancer using contrast-enhanced US.

The study was approved by the institutional ethics committee, and written informed consent was obtained. Between January 2012 and April 2014, 25 patients with biopsy-confirmed T1 breast cancer underwent RF ablation therapy in one institution. We examined 25 patients with 25 T1 breast cancers by contrast-enhanced MRI/CT, and contrast-enhanced US before and after RF ablation therapy. US guided RF ablation was performed using a 17-gauge internally cooled electrode (Cool-Tip™, Valleylab, Boulder, CO, USA) under general anesthesia. After injection 0.015mL/kg body weight of Sonazoid®(perflubutane), contrast-enhanced US was performed at a low mechanical index (0.17-0.24). Therapeutic success was defined as a lack of contrast enhancement by contrast-enhanced MRI, US and non-viable cancer tissues by US guided vacuum assisted biopsy (VAB) or core needle biopsy (CNB).

Contrast-enhanced US and MRI four weeks or more after RF ablation therapy showed ablation zones and adequate tumor necrosis in all 25 cancer lesions treated. Contrast-enhanced US made it possible to see that tumor vessels of treated lesions had disappeared after treatment. Contrast enhanced MRI showed a lack of stain with ring-like enhancement of ablation zone and non-viable tissues were seen by VAB and/or CNB in 25 ablation zones.

Contrast-enhanced US using Sonazoid® was useful modalities for evaluating the efficacy of RF ablation therapy in breast cancer lesions.
Title: $^{18}$F-fluoro-2-deoxy-glucose positron emission tomography/computed tomography evaluation shows the utility for predicting postoperative outcomes on Luminal types breast cancer patients

Kenjiro Aogi¹, Yoshifumi Sugawara¹, Sachiko Kiyoto¹, Takayuki Kadoya², Hideo Shigematsu², Norio Masumoto² and Morihito Okada³. ¹NHO Shikoku Cancer Center, Matsuyama, Ehime, Japan and ²Hiroshima University, Hiroshima, Japan.

Body: Background: Hormonal receptor-positive, i.e. Luminal types, breast cancer has better prognosis compared with other phenotypes, but predictive factors for postoperative outcomes have been in research besides hormonal receptor expressions. $^{18}$F-fluoro-2-deoxy-glucose positron emission tomography/computed tomography ($^{18}$F-FDG PET/CT) using maximum standardized uptake value (maxSUV) has been reported its utility as one of predictive markers for relapse-free survival (RFS) on breast cancer patients. In this retrospective study, the utility of $^{18}$F-FDG PET/CT was evaluated on predicting postoperative outcomes especially on Luminal types breast cancer patients. Methods: Three hundred forty four breast cancer patients with clinical Stage I-III who underwent preoperative $^{18}$F-FDG PET/CT were enrolled between January 2006 and December 2011 in two institutes. Patients classified into Luminal types, Luminal A (166 patients): Estrogen receptor (ER)(+), Progesterone receptor (PR)(+), Nuclear grade (NG) 1-2 or Luminal B (96 patients): ER(+) or PR(+), HER2(-), NG3, were evaluated in this study. Moreover, patients were also divided in two groups according to cut-off maxSUV on receiver operating characteristic (ROC) analysis (≤4.0 group vs >4.0 group, AUC=0.830). Statistical analyses were performed using Student t test and log-rank test, and p values of less than 0.05 were considered to be statistically significant. Results: Significant correlations were shown between maxSUV and clinical T-factor, nuclear grade, vascular invasion and presence or absence of recurrence (p<0.0001, p<0.0001, p=0.0181, and p=0.0056, respectively). In uni- and multivariate analyses using Cox model for recurrence, only maxSUV was shown to be significant (p=0.021 and p=0.043, respectively). In RFS, the maxSUV≤4.0 group showed significantly better prognosis compared to that of the maxSUV >4.0 group (p=0.003). Conclusion: $^{18}$F-FDG PET/CT using maxSUV was concluded to be useful for predicting postoperative prognosis on luminal types breast cancer patients.
Title: Clinical studies of palpation imaging of the breast on over 1000 patients

Cary S Kaufman¹, Jae S Son², Eli Yered² and Armen Sarvazyan³. ¹Bellingham Regional Breast Center, Bellingham, WA; ²Medical Tactile, Inc, Los Angeles, CA and ³ARTANN Laboratories, Inc, West Trenton, NJ.

Body: INTRODUCTION
Palpation Imaging (PI) of the breast is based on the principles of tactile imaging, a method for measuring the elasticity lesions using a tactile sensor array. PI provides objective data beyond subjective manual palpation by quantifying the shape and hardness of a lesion as well as creating a permanent digital image. PI is also known as "Tactile Imaging", "Mechanical Imaging", "Stress Imaging" or "Computerized Palpation". It quantitatively evaluates mechanical and structural properties of a breast lesion that is altered by tumor growth, and provides a quantitative characterization of the detected lesion. PI is a radiation-free and an inexpensive in comparison to other imaging devices. The purpose of this paper is to evaluate the clinical efficacy of PI by summarizing all clinical studies conducted to date with this technology.

METHODS
The two step process to identify the clinical presence of a breast cancer include identifying the presence of an abnormality and secondarily to determine if that abnormality is malignant. Not all studies examined each portion of this two-step process. There have been 9 clinical studies involving 1,155 symptomatic patients using PI in the U.S., China, and UK. To examine the ability of PI to detect an abnormal breast mass, we reviewed the sensitivity comparisons with CBE. To determine whether a breast lesion was malignant, we reviewed the analysis of the sensitivity, specificity and accuracy for the standard imaging modalities; mammography, breast ultrasound, clinical breast examinations (CBE) and MRI using pathology as the gold standard. Calcifications were not included because they represent DCIS which does not present clinically and is the subject of over diagnosis.

RESULTS
All studies included in this initial meta-analysis were on symptomatic patients.
To identify the presence of an abnormality, the sensitivity of PI to detect breast masses was 89% in comparison with CBE which was 83%.
To identify the presence of breast cancer,
- The sensitivity of PI in detecting breast cancer was 85%, in comparison to CBE (59%), mammography (76%) and ultrasound (90%).
- The specificity of PI in detecting breast cancer was 79% in comparison to CBE (78%), mammography (71%) and ultrasound (79%).
- The Accuracy of PI in detecting breast cancer was 82% comparison with CBE (67%), mammography (74%) and ultrasound (84%).

CONCLUSIONS
A summary of clinical studies conducted on symptomatic patients to date suggest that PI is (a) sensitive in the detection of breast masses and b) identifies breast cancer with similar sensitivity and specificity compared with other standard imaging modalities while being cost effective. PI may fill a gap in developing countries where little breast screening infrastructure exists. Ongoing
clinical research with PI is warranted to evaluate its potential in the early diagnosis and screening for breast cancer in the U.S.
Contrast enhanced spectral mammography (CESM) is a new breast imaging contrast study: A review of indications, protocol, interpretation and pitfalls

Lydia Liao¹, Luna Li¹, Pauline Germaine¹, Elizabeth Tinney¹, Kristin Brill² and Karen Hendershott². ¹Cooper University Hospital Women's Imaging, Voorhees, NJ.

Purpose: This presentation is to discuss the indications, protocol, interpretation and pitfalls of CESM using illustrations of breast malignant and benign cases performed in our institution, after a brief literature review. CESM characteristics for both benign and malignant lesions are defined after comparison to other imaging studies and correlation to final tissue diagnosis.

Methods: 1000 CESM cases including 100 breast cancer and 200 benign lesions were retrospectively analyzed. These cases were performed in our institution from October 2012 to March 2014. GE Senographe Essential Full Field Digital System (SenoBright) was utilized for CESM studies. Both low and high energy images were obtained after intravenous 75-100cc Isovue 370 administration at flow rate of 1.5-2cc per second. Both low energy and subtracted images were reviewed on GE Centricity Imagecast on 5 megapixel monitor. Abnormal CESM lesions underwent further evaluation and tissue sampling for a final diagnosis to determine the presence of breast cancer.

Results: CESM is one of the contrast studies. It provides both morphologic and functional information of breast lesions. The sensitivity of CESM for cancer detection was 93-100% per patient in contrast to 95-100% of breast MRI. There are morphological and enhancement features for both malignant and benign lesions on CESM. CESM could pick up lesions when regular digital mammography and ultrasound are negative. CESM is a part of diagnostic study on selected patients. It has a short duration exam time and results are easily accessible. Some CESM artifacts are unique and commonly occurred.

Conclusion: CESM is a new breast imaging contrast study. The sensitivity for breast cancer detection is comparable to breast MRI. With its easy accessibility and cost effectiveness, CESM may play an important role in breast cancer detection in conjunction with diagnostic mammography and breast ultrasound. Recognition of CESM artifacts helps to increase diagnostic accuracy.
Role of FDG-PET/CT in prediction of underestimation of invasive breast cancer in cases of ductal carcinoma in situ diagnosed at needle biopsy

Hideo Shigematsu\(^1\), Takayuki Kadoya\(^1\), Noriko Yoshimura\(^1\), Keiko Kajitani\(^1\), Akiko Emi\(^1\), Noriko Masumoto\(^1\), Rumi Haruta\(^2\), Tsuyoshi Kataoka\(^2\) and Morihito Okada\(^1\). \(^1\)Research Institute for Radiation Biology and Medicine, Hiroshima University, Hiroshima, Japan and \(^2\)Hiroshima University, Hiroshima, Japan.

**Body:** Background: The aim of this study was to evaluate the significance of 18F-fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) for predicting the underestimation of invasive breast cancer in cases of ductal carcinoma in situ (DCIS) at needle biopsy.

Patients and Methods: Of 83 consecutive cases with diagnoses of DCIS at primary needle biopsy who underwent curative surgery between 2010 and 2013, the association between the maximum standardized uptake value (SUVmax) on FDG-PET/CT before excision and the underestimation of invasive breast cancer was examined.

Results: There were 29 (34.9%) cases diagnosed to have invasive breast cancer at excision. Receiver operating characteristics (ROC) curve analysis showed the cutoff value of SUVmax to predict underestimation of invasive breast cancer was 1.6. The rates of underestimation were 61.5% for patients with a tumor of SUVmax > 1.6 and 11.4% for patients with a tumor SUV max \(\leq\) 1.6 (p < 0.001). High value of SUVmax was significantly associated with symptomatic presentation (p < 0.001), palpability (p < 0.001), mass formation (p = 0.013), high Breast Imaging Reporting and Data System category (p = 0.01) and core needle biopsy (p = 0.007). In multivariate analysis, high SUVmax was only significant predictive factor of underestimation of invasive breast cancer (HR 11.7, 95% CI 3.70-37.0, p < 0.001).

**Conclusion:** SUVmax on FDG-PET/CT is useful for predicting the underestimation of invasive breast cancer in cases of DCIS at needle biopsy.
**Title:** Cardiac function in BRCA1/2 mutation carriers with a history of breast cancer (BC) treated with anthracyclines (anthra)

Filipa Lynce¹, Ana Barac², Karen L Smith⁴, Mihriye Mete⁵, Lynette Wray², Madeline Nardacci², Pia Herbolsheimer¹, Raquel Nunes¹, Sandra M Swain¹, Robert Warren³ and Claudine Isaacs¹. ¹Washington Cancer Institute, MedStar Washington Hospital Center, Washington, DC; ²MedStar Heart Institute, MedStar Washington Hospital Center, Washington, DC; ³Lombardi Comprehensive Cancer Center, MedStar Georgetown University Hospital, Washington, DC; ⁴Johns Hopkins Sidney Kimmel Cancer Center, Washington, DC and ⁵MedStar Health Research Institute.

**Body:** Introduction: Animal data suggest that cardiac-specific loss of BRCA1/2 genes leads to increased cardiac dysfunction in the setting of stressors such as ischemia or anthra chemotherapy (CT). Women with BRCA1/2 mutations who develop BC may receive anthra-based CT. It is not known whether BRCA1/2 mutation carriers treated for early stage BC with anthra-based CT are at higher risk for anthra-induced cardiac toxicity than similarly treated women with sporadic BC. This study investigates left ventricular ejection fraction (LVEF) and myocardial global longitudinal strain (GLS), a novel echocardiographic measure of cardiac contractility, in women with and without BRCA1/2 mutations who were treated with anthra-based CT.

Methods: We identified 41 women with a history of BRCA1/2 mutation-associated BC and 52 women with a history of sporadic BC, all of whom received anthra-based adjuvant or neoadjuvant CT. We excluded women who received HER2 therapy or who had stage IV disease. BC CT was completed at least 6 months prior to study enrollment. All participants completed a cardiac questionnaire and underwent a comprehensive 2D and 3D echocardiographic exam with assessment of myocardial GLS using speckle-tracking software (QLAB10, Philips, Andover, MA). Abnormal LVEF was defined as less than 55% (50-54.9% borderline reduced and 40-49% mildly reduced) and abnormal GLS was defined as absolute value of less than 18.9%. Patients with history of hypertension (HTN) were excluded from this analysis to avoid confounding effects of HTN on GLS.

Results: We present data on 57 normotensive participants, 34 BRCA1/2 mutation-carriers and 23 non-mutation carriers. Mean age was 49.5 +/- 8.7 years in the BRCA mutation-carrier group and 51.1 +/- 8.7 years in the non-mutation carrier group (p=0.496). Women with BRCA1/2 mutations were more likely to be Caucasian (p=0.026) and have undergone oophorectomy (p<0.001). The average time from anthra treatment to study enrollment was 5 +/- 4.4 years. Groups were well balanced with regards to age, diabetes, hyperlipidemia, history of coronary disease, smoking and cumulative dose of anthra. Four BRCA1/2 mutation-carriers (12%) and 4 non-mutation carriers (17%) had reduced GLS (p= 0.450). Mean LVEF was similar between the groups: LVEF was borderline reduced in one BRCA1/2 mutation-carrier (3%) and borderline or mildly reduced in 4 non-mutation carriers (18%)(p= 0.091).

Conclusions: In this population, reduced LVEF and myocardial GLS were present in a small percentage of women treated with anthra-based CT for early stage BC. However, reduction in LVEF and myocardial GLS did not differ between the BRCA1/2 mutation carriers and the women with a history of sporadic BC. Larger studies are needed to definitively rule out a difference in cardiac toxicity by BRCA mutation status in BC survivors treated with anthra. AB is supported by Georgetown-Howard Universities Center for Clinical & Translational Science (GHUCCTS) post-doctoral KL2 Award (5KL2TR000102-04).
Title: CYP2D6 intermediate metabolizers includes patient groups with distinct metabolic activity

Daniel L Hertz¹, Anna C Snavely², Howard L McLeod³, Christine M Walko³, Joseph G Ibrahim², Steven Anderson⁴, Karen E Weck², Peter Rubin³, Oludamilola Oajide⁶, Susan Moore⁶, Rachel Raab³, Daniel R Carrizosa⁶, Steven Corso⁶, Gary Schwartz⁸, Jeffrey M Peppercorn¹⁰, James P Evans¹⁰, Zerusesenay Desta¹³, David A Flockhart¹³, Lisa A Carey² and William J Irvin Jr¹⁴.

Background: Tamoxifen is a selective estrogen receptor modulator that is the most commonly used and cost effective hormonal agent for pre-menopausal hormone-receptor positive breast cancer patients. CYP2D6 activity phenotype, which is classified by genotype, predicts the extent of metabolic activation of tamoxifen to endoxifen. We previously reported that increasing the daily dose to 40 mg/day in intermediate metabolizers (IMs), but not poor metabolizers (PMs), achieves target endoxifen concentrations, defined as that of extensive metabolizers (EMs) on 20 mg/day. There was substantial endoxifen variability in the IM phenotype group, which is composed of several discrete diplophenotypes (EM/IM, EM/PM, IM/IM, IM/PM). We enrolled a second, larger cohort of patients in order to determine whether these diplophenotypes should be combined into a single IM phenotype or segregated.

Methods: 380 patients on tamoxifen ≥ 4 months and not on potent CYP2D6 inhibiting medications enrolled in Lineberger Comprehensive Cancer Center (LCCC) trial 0801. Genotyping was performed using the Amplichip® CYP450 test (Roche Diagnostics) for CYP2D6, followed by systematic assignment of phenotype based on diplophenotype. Tamoxifen was increased from 20 to 40 mg/day in PMs and IMs. Endoxifen concentrations in IM diplophenotypes were compared with EM/EMs and PM/PMs at baseline and at 4 months (after dose increase in patients with IM and PM phenotypes).

Results: After exclusion of UM patients and patients missing endoxifen data at baseline and/or 4 months, 295 patients were included in this analysis. At baseline the EM/IM patients had similar endoxifen level to the EM/EM patients while the IM/IM and IM/PM patients had similar levels to the PM/PMs. After 4 months on 40 mg/day the endoxifen concentrations in EM/IM patients were significantly greater than EM/EMs; EM/PM and IM/IM patients were similar to EM/EMs; but IM/PM patients remained significantly lower than EM/EMs and similar to PM/PMs (See Table 1 for results).

Conclusions: The large group of patients currently defined as CYP2D6 intermediate metabolizers is comprised of four distinct CYP2D6 diplophenotypes. The most metabolically active diplophenotype (EM/IM) are very similar to EM/EMs while the least active diplophenotype (IM/PM) are similar to PM/PMs. A more accurate CYP2D6 activity classification system may be necessary if genetic association testing and genotype-guided therapy are pursued.

Title: Experience in the community oncology practice with a 25-gene hereditary cancer panel

Sami Diab1, Patricia Rodriguez2, Anna Leininger3, Lisa Clark4, Mike F Janicek5, Ellen B Smith6, John Sandbach6, Jennifer Saam7 and Lucy Langer5. 1Rocky Mountain Cancer Centers and Colorado Integrative Care, Aurora, CO; 2Virginia Cancer Specialists, Arlington, VA; 3Minnesota Oncology, Woodbury, MN; 4Compass Oncology, Portland, OR; 5Arizona Oncology, Scottsdale, AZ; 6Texas Oncology, Austin, TX and 7Myriad Genetic Laboratories, Inc, Salt Lake City, UT.

Body: Introduction:
The identification of patients with an inherited cancer syndrome is becoming increasingly relevant in the treatment and prevention of cancer. Testing with a panel of genes provides the opportunity to rapidly identify or rule out deleterious mutations in several genes simultaneously and, thus, has the potential to streamline the testing process and more efficiently and accurately provide results. We report on the experience of panel-based testing in the community oncology setting.

Objectives:
To evaluate the performance of a 25-gene hereditary cancer test in the community oncology setting and describe the patient characteristics and test findings.

Methods:
We retrospectively evaluated the 25-gene panel testing data obtained between September 2013 and February 2014 in 6 large community oncology practices. The gene panel was based on next generation sequencing and rearrangement analysis of 25 genes with cancer risk data: BRCA1, BRCA2, MLH1, MSH2, MSH6, PMS2, EPCAM, APC, MUTYH, CDKN2A, CDK4, PALB2, CHEK2, SMAD4, BMPR1A, STK11, TP53, CDH1, PTEN, ATM, NBN, BARD1, BRIP1, RAD51C, and RAD51D. Personal and family history was obtained by health care provider report on test requisition forms.

Results:
The panel test was performed on 359 individuals during the time period. 69.9% of these patients had a phx of at least one of the eight panel cancers: breast, ovarian, colorectal, endometrium, pancreas, melanoma, prostate, and/or stomach. cancer diagnosis. 97.8% of the patients tested met the 2013 NCCN guideline criteria for HBOC, 2012 NCCN guideline criteria for Lynch Syndrome, or both. 37 pathogenic mutations were found in 34 distinct patients. The variant rate in this population was 35.4%. Mutations were identified in 16 different genes, and only 20 of the 37 mutations (54.1%) were found to be in the 6 genes included in HBOC and Lynch Syndrome testing (BRCA1, BRCA2, MSH6, MLH1, MSH2, PMS2).

Conclusion:
The 25-gene hereditary cancer panel increased the identification of deleterious mutations which would otherwise not have been detected. The variant rate in this setting is similar to the rate reported previously in both community and academic centers where panel testing is used. Use of a hereditary cancer panel in the community oncology practice may improve detection rates and provide an opportunity for enhanced cancer management.

Title: The impact of Angelina Jolie (AJ)'s story on genetic referral and testing at an academic cancer centre

Jacques Raphael¹, Sunil Verma¹, Paul Hewitt¹ and Andrea Eisen¹. ¹Sunnybrook Odette Cancer Centre, Toronto, ON, Canada.

Body: Background
In May 2013, AJ revealed to the media that she had undergone preventive double mastectomy. The actress had a family history of breast and ovarian cancer and tested positive for the BRCA1 gene mutation. Media coverage has been extensive, but it's not clear what messages the public and professional medical staff took from this personal story.

Methods
We conducted a retrospective review using data from the clinical database of the Familial Cancer Program in a tertiary care cancer centre. The impact of AJ's story on genetic counseling referrals was assessed by comparing the number of referrals made before and after the story. In addition, the appropriateness of referrals was reported by comparing the number of patients who qualified for genetic testing as defined by the Ontario Ministry of Health and Long Term Care and the ones who were found to carry a BRCA1/2 mutation before and after the media release. We previously reported the impact of AJ's story, 6 months before and after, and showed that all the numbers practically doubled. This is an update of this assessment 1 year before and after the story.

Results
The increase in the number of women referred for genetic counseling was persistent after one year with an increase by 88% compared to 90% originally: 1042 referrals before versus 1962 referrals after. There was still an increase in the number of women who qualified for a genetic testing, but it was was less than previously reported. Originally there was an increase of 105% after 6 months. After 12 months, the increase is 68%: 493 women qualified for the testing before versus 827 women after. Furthermore the preliminary increase in the number of BRCA1/2 carriers identified is also less pronounced. The preliminary increase was by 110%. After 12 months, it is 42%: 80 BRCA1/2 carriers identified (45 BRCA1, 35 BRCA2) before versus 114 after (63 BRCA1, 51 BRCA2).

Conclusion
In our preliminary report we showed that after AJ's story, the number of referrals doubled and the quality of referrals remained the same. In this updated analysis, the number of referrals after the story remained as high as previously, however the quality of referrals did not remain the same. With the longer period of observation, fewer referred women qualified for genetic testing and fewer BRCA1/2 carriers were identified. If the positive "celebrity effect" reported previously will begin to subside, our next challenge will not only be to meet the increased demand for cancer genetic services but also to ensure that referrals to our clinic are appropriate by working to reduce the referrals of low risk women triggered by media attention.
Title: Genetic variant in the OPG gene is associated with aromatase inhibitor-related musculoskeletal toxicity in breast cancer patients

Anneleen Lintermans¹, Kathleen Van Asten¹, Annouschka Laenen¹, Thomas Van Brussel¹, Johan Verhaeghe¹, Dirk Vanderschueren¹, Diether Lambrechts¹ and Patrick Neven¹. ¹KU Leuven, Leuven, Belgium; ²VIB and ³University Hospitals, Leuven, Belgium.

Body: Background
Aromatase inhibitor (AI) therapy is associated with musculoskeletal toxicity, which adversely affects quality of life and therapy adherence. Our objective was to evaluate genetic predictors for endocrine therapy-related musculoskeletal pain in a prospective cohort study, which was previously published.

Patients & methods
254 early breast cancer patients starting AI (n=159) or tamoxifen therapy (n=95) were included in this genetic biomarker study. Musculoskeletal symptoms were assessed at baseline and at 3, 6 and 12 months thereafter. AI-induced musculoskeletal pain was defined as an increase in arthralgia or myalgia relative to baseline. Single nucleotide polymorphisms (SNP) in candidate genes involved in estrogen signaling or reported to have associations with AI-related musculoskeletal pain or estrogen levels were selected. Of the 40 selected SNPs, 7 failed genotyping and were excluded from further analysis.

Results
Twenty SNPs exhibited a minor allele frequency <0.05 and were omitted from the final analysis. Overall, 13 SNPs in CYP19, CYP17, osteoprotegerin (OPG) and estrogen receptor 1 were included.

74% of AI-users reported new or worsened musculoskeletal pain compared to 33% of tamoxifen-treated patients. The OPG SNP rs2073618 was significantly associated with AI-induced musculoskeletal toxicity after correction for multiple testing (p=0.039). None of the other SNPs showed significant associations, both in AI and tamoxifen-treated patients.

Conclusion
The SNP rs2073618 in OPG predicts the risk of musculoskeletal symptoms with AI therapy, which has not been reported so far. Validation of this finding and further functional studies are needed.
Title: BRCA1 and BRCA2 mutations in ethnic Lebanese Arab high risk women for hereditary breast cancer

Nagi El Saghir¹, Nancy Uhrhammer², Hussein Assi¹, Katia Khoury¹, Stephanie Decousous², Yannick Bidet², Sara Jaber¹, Raghid Charara¹, Rania Farhat¹, Ziad Salem¹, Ali Shamseddine¹, Arafat Tfayli¹, Jaber Abbas¹, Faek Jamal¹, Muhieddine Seoud¹, Deborah Armstrong³, Yves-Jean Bignon² and Nathalie Zgheib¹. ¹American University of Beirut Medical Center; ²Centre Jean Perrin, Clermont-Ferrand, France and ³Johns Hopkins Kimmel Cancer Center.

Body: Background: Breast cancer is the most common malignancy in women in Lebanon and Arab countries with 50% of cases below age 50. The incidence of hereditary breast cancer in Lebanese and Arab women is unknown.

Methods: 250 Lebanese women with breast cancer, of young age with or without family history, were recruited at the American University of Beirut Medical Center (AUBMC) between 2009 and 2012. Study was approved by IRB. All signed an informed consent. Risk assessment questionnaire, medical chart review, and whole blood were collected. Coding exons and intron-exon boundaries of BRCA1 and BRCA2 were sequenced. Full BRCA gene sequencing was performed at Institut Jean Perrin, France. Study was funded in part by an Ethnic Research Initiative (ERI) grant awarded by GSK.

Results:
14 out of the 250 patients (5.6%) had a deleterious BRCA mutation (7 BRCA1, 7 BRCA2) and 31 (12.4%) had a variant of uncertain significance (VUS). Table 1 shows deleterious BRCA mutations based on age group and FH.

All 7 BRCA1 mutation carriers had a positive family history, were between 32 and 48 years of age, and had Grade 3 IDC with negative ER, PR, HER2 receptors (TNBC). Six BRCA2 mutation carriers had IDC with positive hormone receptors (HR) and 2 had HER2-positive disease. We found 31 VUS. One VUS (BRCA2) was seen in two sisters with breast cancer. One VUS (BRCA2) was seen in 4 patients and another in 2 patients, while 2 VUS (BRCA1) mutations were seen in 2 sets of 2 patients. The significance of these VUS cannot be ascertained at this time. Haplotype analysis is ongoing.

Conclusions:
This is the first large study of ethnic Lebanese Arab women with breast cancer. The prevalence of BRCA deleterious mutations in women with breast cancer who are considered high risk of carrying a BRCA mutation is 5.6% in our total cohort, while in patients ≤40 with positive FH it is 10.6%. Those numbers are lower than expected from US and European populations. Tumor grade and pathology characteristics in this patient population correlated with that previously documented for BRCA1 (TNBC) and BRCA2 (positive HR) associated breast cancers. Our data supports use of young age together with positive FH should be used to select patients for counseling and BRCA testing in Lebanon and Arab countries with resource-sensitive guidelines. Several VUS were found in patients and sisters with breast cancer. The finding that 94.4% of high risk patients had no deleterious BRCA mutations suggests the need to look for alternate gene mutations and other factors that may contribute to the development of breast cancer in these high risk patients. Conclusions regarding haplotypes and diversity will be reported at the meeting.

Title: Different genomic rearrangements account for 17% of BRCA1/2 mutations in Greece

Angela Apessos¹, Eirini Papadopoulou¹, Vassiliki Metaxa-Mariatou¹, Konstantinos Agiannitopoulos¹, Christos Markopoulou², Vasileios Venizelos³, Grigoris Xepapadakis⁴, Maria Vasilaki-Antonatou⁵, Antonios Keramopoulos⁶, Nikolaos Bredakis⁶, Aristidis Tsiftsoglou⁷, Georgios Kesisis⁷, Stylianos Kakolyris⁸, Nikolaos Touroutoglou⁹, Ioannis Natsiopoulos⁹, Konstantinos Papazisis¹⁰ and Georgios Nasioulas¹.

¹Genekor MSA, Athens, Greece; ²Medical School, University of Athens, Athens, Greece; ³Metropolitan Hospital, Athens, Greece; ⁴Rea Maternity Hospital, Athens, Greece; ⁵IASO General Hospital, Athens, Greece; ⁶IASO Maternity Hospital, Athens, Greece; ⁷St Luke's Hospital, Thessaloniki, Greece; ⁸University General Hospital of Alexandroupoli, Alexandroupoli, Greece; ⁹Interbalkan Medical Center of Thessaloniki, Thessaloniki, Greece and ¹⁰Euromedica General Clinic of Thessaloniki, Thessaloniki, Greece.

Body: AIM: The aim of this study was to further delineate the extent and nature of mutations in the BRCA1 and BRCA2 genes, responsible for hereditary breast and ovarian cancer in Greek families.

MATERIALS & METHODS: Genomic DNA was isolated from whole peripheral blood of patients referred to our center for mutation analysis of the BRCA1 and BRCA2 genes. Patients were included on the basis of affected family members, types of cancer present in the family and age at diagnosis of breast cancer in the proband. Families were subdivided into high, medium and low risk depending on the number of affected family members, types of cancer diagnosed in the family and age at diagnosis of affected family members. In total, 675 families have been analyzed by our group in the past 4 years. Mutation analysis in all cases included sequencing of the coding region and the splice sites of the two genes. In addition, MLPA analysis was carried in 585 of the patients.

RESULTS: In total, a pathogenic mutation has been identified in 12% of the 675 patients analyzed. Of the 78 mutations identified in total, 13 (17%) were large genomic rearrangements. These were deletions of exons 8, 20, 23, 23-24 and the entire BRCA1 gene, in addition to a duplication of exons 3-8 of the BRCA1 gene. As far as BRCA2 is involved deletions of exons 3, 15 and the entire BRCA2 gene were detected. All deletions were confirmed by use of other MLPA probe sets and/or relative quantitation by Real Time PCR. Of the rearrangements identified, two, namely deletions of exon 20 and exons 23-24 of the BRCA1 gene were identified in more than one unrelated families. In addition, the recurrent mutations 5382insC and G1738R, which have been previously identified as founder mutations in the Greek population, were identified in multiple unrelated analyzed families.

CONCLUSIONS: Our results indicate that different large genomic rearrangements account for an important proportion (17%) of the mutations in the BRCA1 and BRCA2 genes, in Greek families at risk of carrying a germline mutation as judged by family / personal history. The use of the available technologies for the identification of such mutational events is therefore necessary when carrying out complete analysis of the genes in high risk families of Greek background.
Title: Identification of BRCA1 and BRCA2 founder mutations in population isolates from Colombia

Luis G Carvajal-Carmona, Anna Marie D Tuazon, Carolina Ramirez, Mabel Bohorquez, Rodrigo Prieto, Jorge Castro, Gilbert Mateus, Magdalena Echeverry, COLOMBUS Consortium, Justo Olaya and Alejandro Velez. 1University of California, Davis, CA; 2University of Tolima, Colombia and 3Hospital Pablo Tobon Uribe, Colombia.

Body: Breast cancer (BC) is the most common malignancy in women. Germline mutations in breast cancer risk genes, such as BRCA1 and BRCA2, account for a large portion of hereditary breast cancer families. The contribution of mutations in breast cancer susceptibility genes has been poorly investigated in minority populations, such as in Hispanics from South America. While mutations in BRCA1 and BRCA2 display a heterogeneous mutation spectrum, specific mutations often occur in population isolates. Using the KASP genotyping technology, we screened unselected Colombian breast cancer patients for three common BRCA1 and one BRCA2 founder mutations in the Hispanic population. The BRCA2 c.2806_2809delAAAC founder mutation was identified in 3 of the 476 BC cases (0.6%). Strikingly, 28 out of 580 cases (5.0%) harbored the BRCA1 founder mutation c.3331_3334delCAAG, which has also been reported in Southern European populations, including Spain and Portugal. The clinical data and family history of these patients have highlighted a distinct geographic region, Neiva, from where these cases originate. 10% of the BC cases recruited from Neiva harbored the same BRCA1 mutation, potentially representing one of the most remarkable founder effects reported in human populations. To date the arrival of the BRCA1 c.3331_3334delCAAG mutation to Colombia, we are completing haplotype analysis of the patients and their families, along with BC cases from Spain and Portugal that harbor the same mutation. Interestingly, haplotype analyses of our BC cases have revealed a haplotype larger than 3.5 cM. In the future, we aim to perform haplotype analysis of family members of the mutation carriers and BC cases from Portugal and Spain to further study the haplotype around this BRCA1 mutation, which will allow us to date the origin of the mutation. By understanding the prevalence of mutations in known breast cancer risk genes in minority populations, cancer disparities can be better addressed and breast cancer screening can be improved. Furthermore, the ability to identify such strong founder effects highlights an advantage of using this Colombian population isolate in facilitating the identification of novel BC risk genes.
Exome sequencing identified emergence of HER2 kinase domain mutations in trastuzumab-resistant breast cancer

Yizhou Jiang¹, Ke-Da Yu¹, Wen-Jia Zuo¹, Yu-Jie Wang¹ and Zhi-Ming Shao¹. ¹Fudan University Shanghai Cancer Center, Shanghai, China.

Purpose
Human epidermal growth factor receptor 2 (HER2)-positive breast cancer is primarily treated with trastuzumab and other HER2-targeted therapies. However, approximately 30% of HER2-positive tumors exhibit de novo resistance, whereas 40% acquire resistance to these therapies. The mechanisms underlying drug resistance are unclear, and a better understanding of acquired resistance to HER2-targeted therapy is essential for the development of more effective therapeutics.

Methods
We enrolled 11 patients with HER2-positive breast cancer, all of whom had been treated with trastuzumab for one year and developed lung metastasis in the follow-up. We conducted exome sequencing of the primary and paired metastatic tumors from four patients. We identified somatic mutations in HER2 (K753E and L755S) affecting the kinase domain only in the metastatic lesions of two cases. Sanger sequencing was performed to analyze all exons of the HER2 gene in the paired primary and metastatic tumors of the remaining seven cases. Furthermore, we enrolled 48 patients with HER2-positive disease who underwent trastuzumab-based neoadjuvant therapy. We performed Sanger sequencing of the HER2 gene in paired tumor DNA before and after neoadjuvant therapy. To determine the phenotype of these mutations, we functionally characterized the HER2 mutations using protein structure analysis, in vitro kinase assays, cell culture, and xenograft experiments.

Results
We identified somatic mutations in HER2 affecting the kinase domain in four of 11 metastatic tumors (one case with K753E and three cases with L755S). None of the primary tumors harbored HER2 mutations. Furthermore, Sanger sequencing in the neoadjuvant setting revealed two of 48 cases harboring HER2 mutations (K753E and L755S) in the post-treatment samples, none of whom had any HER2 mutation in the paired pre-treatment tumor. Protein structure visualization hinted that the HER2 L753 and L755 side chains were in close proximity to the binding site for small-molecule inhibitors, indicating mutations at this residue might produce drug resistance. In vitro kinase assays revealed that HER2 K753E had greater tyrosine kinase-specific activity than wild-type. HER2 autophosphorylation, phosphorylation of HER2’s dimerization partners (EGFR or HER3) and downstream signaling proteins were significantly upregulated in MCF10A and MCF7 cells overexpressing HER2 K753E or L755S. Trastuzumab or lapatinib treatment did not decrease the number of colonies formed in MCF10A cells transduced with K753E or L755S. MCF7 cells bearing K753E or L755S mutant could reverse the inhibition of lapatinib in xenografts. The MCF10A-HER2 K753E and L755S cells were resistant to trastuzumab (IC₅₀>1000μg/mL) and lapatinib (IC₅₀>10μmol/L) but could be readily inhibited by neratinib (IC₅₀ of 15 nmol/L), an irreversible kinase inhibitor of HER2.

Conclusion
These data implicate that mutations in HER2 kinase domain are a key mechanism in resistance to HER2-targeted therapy. The selection of functional HER2 mutations might act as potential drivers of trastuzumab resistance during the progression of HER2-positive disease. Furthermore, more potent HER2 inhibitors such as neratinib might be of therapeutic benefit for trastuzumab-resistant breast cancer.
Title: Prognostic and predictive implications of monosomy 17 in curable HER2-amplified breast cancer

David Page¹, Yong H Wen¹, Dana Dure¹, Clifford Hudis¹, Edi Brogi¹ and Heather McArthur¹. ¹Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Background: Monosomy of chromosome 17 is identified in approximately 6% of HER2-amplified breast cancers. Monosomy 17 has been retrospectively associated with inferior response to trastuzumab in the metastatic setting. The adverse impact of monosomy 17 could be related to the loss of putative genes encoding DNA-binding regulatory proteins, such as ROX or TOP2A. To date, the prognostic or predictive significance of monosomy 17 in women with potentially curable HER2-positive breast cancer has not been fully evaluated.

Methods: Through a search of institutional databases, we identified women with HER2+ breast carcinoma with monosomy 17 by fluorescence in situ hybridization (FISH) and treated at our center between 1/1/00 and 6/1/11. HER2-amplification was defined as a HER2/CEP17 copy ratio ≥2.0, and monosomy 17 was defined as the presence of ≤1.4 CEP17 copies/cell. Clinical outcomes were determined by chart review, defined by Standardized Definitions for Efficacy (STEEP). Differences in treatment and other disease characteristics were compared by the log-rank test.

Results: We identified 99 women with stage I-III HER2-positive breast cancer showing monosomy 17 by FISH: 51% (n=50) were treated with trastuzumab plus chemotherapy (tras/chemo), 31% (n=31) with chemotherapy (chemo alone), and 18% (n=18) with neither (no tras/chemo). An adjuvant anthracycline was administered in 82% of women in the tras/chemo group and 97% of women in the chemo group. The 3 treatment groups were balanced for age (median: tras/chemo 49y; chemo 53y; neither 56y), but were not balanced for hormone receptor (HR)-status (HR+: tras/chemo 96%; chemo 81%; neither 78%, p=0.04) or TNM stage (stage III: tras/chemo 16%; chemo 27%; neither 0%, p=0.01). With a median follow-up of 7y (0.16-13.4y), 4y distant relapse free survival (DRFS) was 100% for the tras/chemo group, 87% for the chemo alone group, and 80% for the no tras/chemo group (p=0.018); and 4y overall survival (OS) was 100% for the tras/chemo group, 93% for the chemo alone group, and 81% for the no tras/chemo group (p=0.005).

Conclusions: Here we report the largest retrospective series of patients with curable HER2-amplified breast cancer and monosomy 17. HER2-amplified monosomy 17 does not appear to adversely affect survival in the curative setting, with outcomes comparable to those reported in large phase III adjuvant trastuzumab trials. Despite receiving less anthracycline-based chemotherapy, better OS and DRFS were observed in women treated with tras/chemo compared with women treated with chemo alone, thereby supporting the critical role of trastuzumab in this patient population, despite data to the contrary from the metastatic setting.
Title: Activating HER2 mutations promote oncogenesis and resistance to HER2-targeted therapies in breast cancer

Wen-Jia Zuo1, Yi-Zhou Jiang1, Ke-Da Yu1 and Zhi-Ming Shao1. 1Fudan University Shanghai Cancer Center, Shanghai, China.

Body: Purpose: Somatic mutations in the tyrosine kinase domain of human epidermal growth factor receptor2 (HER2) have been reported to lead to resistance to HER2-targeted therapies in HER2-positive breast cancer, while activating mutations of HER2 have been described in HER2-negative breast cancer. The prevalence, clinicopathological characteristics, and phenotypes of HER2 mutations are not well established, thus we sought to describe the HER2 mutation profile of Chinese breast cancer patients.

Methods: DNA samples were gathered from breast cancer patients undergoing neoadjuvant (N=102) or adjuvant therapy (N=498) at Fudan University Shanghai Cancer Center between January 1, 2006 and December 31, 2012. Sanger sequencing was performed to analyze all exons of HER2 to identify somatic mutations. To determine the phenotypes of novel HER2 mutations, in vitro kinase assays, protein structure analysis, cell culture, and xenograft experiments were conducted.

Results: 10 HER2 somatic mutations were observed in 17 patients (17/600, 2.83%). 7 novel HER2 mutations were uncovered, 4 in the transmembrane domain and 3 in the kinase domain. Kinase domain mutations L768S and V773L were detected in HER2-negative tumors, while K753E was found in HER2-positive disease. In vitro kinase assays found that L768S and V773L exhibited a significant increase of tyrosine kinase-specific activity, while Western blots showed that L768S and V773L strongly increased phosphorylation of all signaling proteins in both MCF10A and MCF7 cell lines, indicating that they were activating mutations. In Matrigel cultures, L768S and V773L formed acini when seeded in vehicle, but maintained spherical morphology when seeded in culture containing trastuzumab. The addition of lapatinib in Matrigel culture inhibited the growth of all except K753E, which was successfully inhibited by neratinib. Similarly, L768S, V773L and K753E increased the number of cell colonies formed in soft agar, trastuzumab and lapatinib treatment decreased the number of colonies formed by L768S and V773L, but only neratinib could inhibit the colony growth of K753E. Xenograft showed L768S and V773L displayed a more rapid growth, while K753E showed resistance to lapatinib in vivo. MCF10A cells bearing K753E mutation were found to be resistant to lapatinib (IC50>10,000 nmol/L), but could be inhibited by neratinib, though requiring a relatively higher dosage (IC50 of 32 nmol/L) than HER2 WT (IC50 of 480 nmol/L for lapatinib, <2 nmol/L for neratinib) and other HER2 mutations. Meanwhile, clinical follow-up showed that the 2 patients with K753E mutation who received adjuvant trastuzumab treatment presented with either brain or bone metastasis, in their 3rd and 5th year after initial cancer diagnosis, suggesting K753E mutation may have a role in trastuzumab resistance as well.

Conclusions: HER2 somatic mutations were found in 2.83% of patients in this study. HER2-positive tumors harboring certain HER2 kinase domain resistance mutations may not benefit from trastuzumab or lapatinib treatment, and neratinib may offer an alternative treatment option for these patients. HER2-negative disease with activating mutations may benefit from HER2-targeted therapies, and may be of interest in prospective clinical trials.
Title: Heterogeneity and clonal evolution revealed by exome sequencing of primary breast cancers with paired metastatic lesions

Una Kjällquist¹, Nicholas Tobin², Rikard Erlandsson¹, Eva Karlsson², Linda Lindström³, Siker Kimbung⁴, Anna Danielsson⁵, Ingrid Hedenfalk⁴, Thomas Hatschek², Sten Linnarsson¹ and Jonas Bergh². ¹Karolinska Institutet, Stockholm, Sweden; ²Karolinska Institutet, Cancer Center Karolinski, Stockholm, Sweden; ³Karolinska Institutet, Stockholm, Sweden; ⁴Lund University, Lund, Sweden and ⁵University of Gothenburg, Institute of Clinical Sciences, Sahlgrenska Academy, Gothenburg, Sweden.

Body: Genomic heterogeneity in primary solid tumors has been extensively studied using deep sequencing technologies during the last decade. However, little has been described about the genomic profiles of the metastatic lesions and their relation to its original malignant cell population. Here, we report the exome sequences of paired primary-metastasis tumors from ten breast cancer patients. The heterogeneity of cancer tumors is today a well-established concept with a low number of genes being recurrently mutated in over 10% of the tumors, for example TP53 and PIK3CA. However, most available data relates to the primary breast cancer tumors and little has been described about the mutational profiles of the metastatic lesions and their relation to its original malignant cell population. Prospective and numerous retrospective studies have demonstrated lack of stability of the standard breast cancer prognostic and therapy predictive factor Er, Pr and Her-2. Altered receptor status in the metastatic lesion occurs at high rates ranging from during cancer progression and is additionally affected by adjuvant therapy with major implications for management of the metastatic disease. Recently, a number of studies have described how genetic diversity develops sequentially from primary tumor, to lymph node and distant metastasis.

We compared the exome sequences from ten pairs of primary breast carcinomas and their metastatic lesion. We found a marked heterogeneity of somatic mutations as well as chromosomal aberrations in the metastatic lesions, which had sometimes greatly diverged from the primary tumors. A number of mutated genes were enriched in the metastases including, significantly, members of the A-kinase anchoring protein (AKAPs), a family of adaptor proteins that anchor Protein kinase A (PKA) to diverse subcellular locations. In addition to somatic mutations and deletions the gene expression of the AKAP family followed a pattern that relates tumor intrinsic subtype with PKA subcellular localization.

Our findings indicate that in metastatic lesions, the primary tumor genome is extensively transformed, with enrichment of mutations in a distinct set of genes. Together, these findings suggest the involvement of AKAPs in the metastatic process and provide a potential avenue for targeted therapy directed at metastatic breast cancer. Molecular and genetic characterization of the metastatic lesions is not only important in the clinical setting but should also provide the means to reveal genetic patterns specific for the disseminated malignancy.
Title: Prevalence of PIK3CA mutations in tumor tissue of a consecutive cohort of breast cancer patients (n=700)

Martina Vetter¹, Kristin Reinhardt¹, Silke Wegener¹, Juergen Dittmer¹, Tilmann Lantzsch², Christoph Uleer³, Susanne Peschel⁴, Jutta John⁵, Volker Hanf⁵, Joerg Buchmann⁷, Karl-Friedrich Bürrig⁸, Edith Weigert⁹, Christoph Thomssen¹ and Eva J Kantelhardt¹.

¹GYN Universitaet Halle-Wittenberg, Halle (Saale), Germany; ²GYN St Elisabeth & St Barbara Hospital, Halle (Saale); ³GYN Praxis Uleer, Hildesheim; ⁴GYN St Bernward Krankenhaus, Hildesheim; ⁵GYN Städtisches Klinikum, Hildesheim; ⁶GYN Klinikum Fürth, Fürth; ⁷Institut fuer Pathologie Martha Maria, Halle (Saale) and ⁸Institut fuer Pathologie Hildesheim, Hildesheim.

Body: Introduction:
The AKT / mTOR pathway is activated by phosphorylation of the lipid kinase phosphatidylinositol 3-kinase (PI3K) and regulates proliferation, apoptosis, survival and adhesion of tumor cells. In up to 30% of breast cancers, dysregulation of PI3K is reported, resulting from mutations in the PIK3CA gene that encodes the catalytic subunit (p110a). Hotspots of mutations were described in exon 9 (helical domain, E542K, G > A) and exon 20 (kinase domain, H1047R, A > G). Prevalence and the prognostic impact of the PIK3CA mutations as well as the predictive value with regard to endocrine therapy are controversially discussed. In this study we describe the prevalence of PIK3CA mutations in a consecutive cohort of breast cancer patients and its association to tumor characteristics and known prognostic factors.

Material & Methods:
Fresh frozen tumor samples were obtained from a consecutive cohort of 700 breast cancer patients (inclusion criteria: pTx pNx M0 Gx HRx HER2x) who were primarily operated in 6 centres between 2009 and 2011. Tumor DNA was extracted and analyzed by conventional and quantitative PCR (exon 9: cosmid 763 and exon 20: cosmid 775). Patient data, tumor characteristics and prognostic factors were obtained from patients charts. ER, PgR and HER2 results were based on local pathology, uPA and PAI-1 values were determined centrally.

Results:
All isolated DNA (n=700) were analyzable by PCR and showed a mutation rate of 22% in the entire cohort; including two tumors with both mutations. Among the tumors with a positive steroid hormone receptor (HR) status (n=606; 87%), we found a mutation rate of 24% for PIK3CA, whereas only 9 (10%) of 94 HR-negative tumors were mutated. Tumors with a PIK3CA mutation were significantly associated with HR positivity / HER2 negativity (p=0.001). 14% of the cohort was HER2 positive. In 98 cases with a HER2 positive tumor 17 DNAs were mutated (17%) and 139 DNAs of the 602 HER2 negative tumors had a positive PIK3Ca mutation status (23%). Of the mutated tumors, 94 % were HR positive, and 11% HER2 positive. Only three samples were HER2 positive and HR-negative. 6% of the mutated tumors were triple negative.

No significant association was found to age, menopausal status, tumor stage, nodal status, grading and uPA/PAI-1 status. Most mutant tumors were histological grade 2 (p=0.001). A quarter of the intermediate risk group according to St. Gallen risk estimation had a somatic PIK3CA mutation.

Conclusion:
In our cohort, nearly all mutated tumors are hormone receptor positive and a minority of all mutated samples is HER2 positive. This data adds important information to the heterogeneous results of other previously published patient cohorts. It suggests a possible role of PI3K-dysregulation with regard to resistance against endocrine therapy and anti-HER2-treatment.
Title: Optimized mixed micellar nanoparticle as carrier improves therapeutic effect of PLK1 siRNA for breast cancer

Shi Liang¹, Xianzhu Yang², Jun Wang² and Erwei Song¹. ¹Breast Tumor Center, Sun Yat-sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, Guangdong, China and ²School of Life Sciences and Medical Center, University of Science and Technology of China, Hefei, Anhui, China.

Body: Small interfering RNA (siRNA) brings a new dawn for the treatment of breast cancer. However, the biggest challenge in systemic administration of siRNA drugs is the siRNA clearance in vivo. Nano drug delivery systems for siRNA delivery have made significant progresses, but the size effect of nanoparticles affecting its efficacy for cancer therapy is controversial. We successfully established a new method for preparing mixed-micelle nanoparticles (MMP) with controllable sizes (40, 90, 130 and 180 nm). All MMPs could load, release and protect siRNA from the RNase degradation. The MMPs were proved to be stable in the serum and with low toxicity. In addition, all MMPs carrying FAM-siRNA were taken up by breast cancer cells, while larger MNPs were more taken up by the cells due to the extra endocytosis pathways. MMPs loaded with Polo-like kinase 1 siRNA (siPLK1) significantly inhibited the proliferation of breast cancer cells and induced cell apoptosis through inhibiting PLK1 gene expression. In addition, such effect was strengthened along with the increased size. Moreover, MMPs loaded with siPLK1 inhibited tumor growth in tumor-bearing mice, but the nanoparticles with average diameter of 90 nm showed strongest effect. Although nanoparticles with smaller diameters (40 and 90 nm) had longer blood circulation time and showed more accumulation in tumor tissue following systemic administration, MNPs with larger diameters (130 and 180 nm) were more efficiently taken up by cancer cells after they arrived the tumor tissue in vivo. Therefore, therapeutic effect of MNPs carry siPLK1 to breast cancer showed an equilibrium effect and reached highest inhibitory effect to tumor growth when nanoparticles with a diameter of 90 nm was used as the carrier. In conclusion, we demonstrate that optimized mixed micellar nanoparticle as carrier of siPLK1 significantly improves the therapeutic effect to breast cancer treatment, which provides a powerful technic to improve the efficacy of siRNA delivery for breast cancer therapy.
Title: Histone deacetylase HDAC7 is a putative therapeutic target in invasive lobular carcinoma

Matthew J Sikora and Steffi Oesterreich. University of Pittsburgh, Pittsburgh, PA.

Body: Invasive lobular carcinoma (ILC) is the second most common histological subtype of breast cancer, accounting for 10-15% of cases. Though ILC represents a minority of breast cancer patients, ILC affects over 30,000 women annually in the US, making ILC the 6th most common women’s cancer. Despite this incidence, no ILC-specific therapeutic options exist. The majority of ILC are estrogen receptor (ER)-positive (>90%); this and other biomarkers suggest that ILC patients are ideal candidates for endocrine therapy. However, the efficacy of endocrine therapy in ILC is poorly understood since no ILC-specific prospective clinical trial data exist. Recent retrospective analyses suggest that a subset of ILC patients may not benefit from endocrine therapy. Understanding the unique mechanisms of endocrine response and resistance in ILC is critical to improving ILC patient outcomes.

We recently identified estrogen-mediated gene expression specific to the ILC cell lines MDA MB 134VI and SUM44PE. ILC-specific ER target genes were enriched for repression by estrogen. Further, tamoxifen regulated estrogen-repressed genes as an agonist in MDA MB 134VI cells, in parallel with tamoxifen-induced growth. Thus, ER-mediated repression of target genes may be critical in maintaining cell growth and survival. Our laboratory previously identified that ER-mediated gene repression in breast cancer cells is mediated by histone deacetylase 7 (HDAC7). E2-induced repression requires specifically HDAC7, not HDAC1-6/8-10. In a panel of breast cancer cell lines, HDAC7 was most strongly expressed in MDA-MB-134VI cells, the only cell line among the panel derived from an ILC. Increased HDAC7 expression in ILC versus invasive ductal carcinoma (IDC) can also be observed in the Cancer Genome Atlas; mean HDAC7 expression in ER-positive tumors is 2-fold higher in ILC (n=148) versus IDC (n=508) (p<0.0001). We hypothesize that HDAC7 mediates the unique ER-mediated gene repression in ILC cells, and may serve as a novel therapeutic target in conjunction with endocrine therapy for ILC.

To model HDAC7 inhibition, we generated stable cell lines carrying inducible HDAC7 shRNA constructs from MCF-7 (IDC) and MDA MB 134VI (ILC). These lines are being used to examine the effects of HDAC7 depletion on estrogen- and tamoxifen-mediated gene expression, cell proliferation, anoikis resistance, and endocrine resistance. Parallel studies using the class Ila HDAC inhibitor MC1568 are being used as proof-of-principle for using HDAC7-specific inhibitors. Additionally, we identified novel splice variants of HDAC7 in breast cancer cells. Based on the mouse homolog Hdac7, these splice variants may alter the ability of HDAC7 to interact with transcription factors, or change its activity as a transcriptional repressor.

Our observations suggest that HDAC7 may mediate ER-mediate gene repression in ILC cells, which may be necessary for cell proliferation and endocrine resistance in this breast cancer subtype. Preclinical studies using ILC model systems will identify the role of HDAC7 and specific splice variants in controlling ER-driven gene expression. Further studies using HDAC7-specific inhibitors will determine whether targeting HDAC7 in ILC patients can improve endocrine response and inhibit endocrine resistance.
Identifying hypermethylated tumor suppressor genes in breast cancer with an in vivo total genome knockdown screen

Margaret Thomas, Krysta Coyle, Mohammad Sultan, Luzhe Pan, Dae-Gyun Ahn, Patrick Lee, Carman Giacomantonio and Paola Marcato. Dalhousie University, Halifax, NS, Canada.

Changes in gene expression are required for the progression of breast cancer; and DNA methylation, which silences tumor suppressor genes, is often responsible for these changes. Several de-methylating/DNA synthesis inhibiting drugs (such as decitabine) are potential breast cancer therapies; however, for their application to be successful, we need to identify which patients would most benefit from these treatments. To accomplish this, the critical genes, which must be silenced by hypermethylation in order for breast cancer to progress, need to be identified. For this purpose, we have performed an in vivo total genome knockdown screen.

A genome-wide lentiviral-based shRNA screen was performed with breast cancer cell line MDA-MB-231 tumors implanted in the mammary fat pads of female NOD/SCID mice, with or without decitabine treatment (50mg/kg). The resulting tumors were harvested and shRNA sequences retrieved and hybridized to a Decode microarray, allowing for the identification of shRNA sequences that were enriched or depleted under decitabine treatment. The enriched shRNA sequences likely target genes of two categories: 1) they are methylated in the tumor and when expressed have tumor suppressive function, or 2) they are required for decitabine-mediated DNA synthesis inhibition and apoptosis. To determine if the shRNA-targeted genes identified in the screen fall within category 1 or 2, further analysis was done using GEO datasets for methylation in breast cancer cell lines, primary tumors, and normal breast tissues.

In replicates of 6 mice, 111 shRNA sequences were enriched more than 2-fold in 5/6 mice. Of the 111 genes, 29 genes showed significant enrichment (p<0.05) in the decitabine-treated tumors. Using the GEO datasets, 19 of those significantly enriched genes fit a tumor suppressor methylation profile and merit further investigation of their methylation status in the MDA-MB-231 cell line. The remaining enriched genes may play a role in DNA synthesis inhibition and apoptosis- this will be confirmed with in vitro apoptosis assays. DAVID analyses did not reveal any functional clustering of the genes of interest, but did implicate several pathways that involved a single potential hypermethylated tumor suppressor gene.

We have identified several genes that are hypermethylated in breast cancer and are potentially involved in tumor progression. Confirmation experiments will reveal a list of genes that when found hypermethylated in patient tumors would identify candidate breast cancer patients who would benefit from decitabine treatment.

Title: Maintenance of a lean phenotype is associated with increased ERβ expression and ERβ gene intron methylation in murine MMTVneu luminal mammary cancer

Emily L Rossi¹, Sarah M Dunlap², Nikki A Ford², Laura W Bowers¹ and Stephen D Hursting¹. ¹University of North Carolina, Chapel Hill, NC and ²University of Texas, Austin, TX.

Body: Background: Obesity is associated with increased breast cancer mortality in premenopausal women, who predominately develop estrogen receptor (ER)-α negative breast tumors. New mechanism-based targets and intervention strategies for offsetting the procancer effects of obesity are urgently needed given the rising rates of obesity in women throughout the world and the lack of effective targeted therapies for ER-negative breast cancer. Unfortunately, the mechanisms by which obesity impacts ER-negative breast cancer prognosis remain unclear. Methods: In this study, we utilized the MMTV-neu transgenic mouse model of Her2+ breast cancer to test the hypothesis that dietary energy balance modulation alters mammary tumor development and progression through epigenetic regulation of ER in the mammary epithelium of these mice. MMTV-neu transgenic mice form spontaneous mammary tumors that progress from an ERα-positive hyperplasia to aggressive ERα-negative ductal adenocarcinomas. Female MMTV-neu transgenic mice were randomized to 3 diet regimens (30/regimen), resulting in either an obese, overweight or lean phenotype. A subset of mice were killed at baseline, 1, 3, and 5 months following diet initiation, and tissues were collected for analysis; remaining animals were followed for up to a 22 month survival study. Results: Gene and protein expression analysis revealed that mammary ERα expression, known to be lost by 8 weeks of age in normoweight MMTV-neu transgenic mice, was maintained in lean mice but lost in the overweight and obese mice (which did not statistically differ in any parameter studied). Additionally, we found lean mice had significantly increased mammary ER gene expression and delayed onset of hyperplasia relative to the overweight/obese mice. ERα and ERβ gene intron methylation increased from 5 months to 12 months on diet in lean mice and conversely decreased in overweight/obese mice, which parallels the ER gene expression data. After 22 months of feeding, lean mice had significantly increased tumor-free survival in relative to the overweight/obese mice. Interestingly, human and mouse HER2+ (but not but not HER2-) breast cancer cell lines, when treated with serum from obese (BMI>30), women resulted in a significant down-regulation of ERβ gene expression. Conclusions: In MMTV-neu transgenic mice, dietary energy balance modulation impacts spontaneous mammary tumor development and ERα and ERβ levels in normal and tumor tissue, possibly through epigenetic mechanisms. Moreover, increased mammary ERβ expression may represent a novel target for interventions to offset the enhancing effects of obesity on breast cancer.
**Title:** Super-enhancer analysis defines breast cancer subtype and identifies tumor dependencies

Matthew G Guenther¹, David A Orlando¹, Matthew L Eaton¹, Cindy A Collins¹, Mei Wei Chen¹, Sneha Solanki¹, Jakob Loven¹, Christian C Fritz¹ and Eric R Olson¹. ¹Syros Pharmaceuticals, Watertown, MA.

**Body:** Epigenomic modifications define gene regulatory features that control transcription and disease cell state. Recent studies of these regulatory features have identified large clusters of enhancers, termed super-enhancers, which define key cell identity and disease genes. Using ChIP-seq and RNA-seq analysis, we have discovered Super-enhancers in breast cancer cell line models and in primary tissue and have characterized their roles in establishing tumor cell state. We find that Super-enhancers recapitulate clinical subgroups in both breast cancer cell line models and in invasive ductal carcinoma. Super-enhancer-associated genes encode known and novel therapeutic targets including kinases, phosphatases, chromatin regulators and transmembrane proteins. Such genes include key drivers such as ERRB2 in HER2+ patient samples, ESR1 in estrogen receptor positive samples, and CCND1 in samples of luminal subtype. We describe the biological and disease relevance of Super-enhancer-associated genes in the context of tumor cell state and drug target discovery.
Title: DNA methylation-based classification are mostly concordant with intrinsic subtypes of breast cancer

Natsue Uehiro1, Fumiaki Sato1, Sunao Tanaka1, Fengling Pu2, Junji Itou1, Shigehira Saji2 and Masakazu Toi1. 1Graduate School of Medicine, Kyoto University, Kyoto, Japan and 2Graduate School of Medicine, Kyoto University, Kyoto, Japan.

Body: Backgrounds:
Breast cancer (BC) is a heterogeneous disease and usually divided into 5 subtypes according to clinicopathologic features. These subtypes have concordance with mRNA-based subtypes called as "intrinsic subtypes". Further gene expression analysis categorized triple negative BCs into 7 sub-subtypes which relate to clinical behaviors. DNA methylation is one of the epigenetic systems to regulate gene transcription. DNA methylation in CpG islands (CGIs) associated with the gene promoter region affects gene expression levels. Recently genome-wide analyses suggested that methylation status not only in CGIs, but also in CpG shores (within 2000 bps from CGIs) and CpG shelves (2000-4000 bps from CGIs) contribute to gene silencing. Thus, we hypothesized that intrinsic subtypes may possess specific methylation profiles especially in regions surrounding CGIs (islands, shores and shelves). To date, several reports demonstrated each intrinsic subtype has specific methylation patterns in CGIs. They indicate that DNA methylation is promising markers for cancer detection, prediction of therapeutic response and clinical outcomes. However, there were no report that conducted a genome-wide high-resolution epigenetic analysis for BC.

Objectives:
This study aims to determine whether specific DNA methylation patterns exist in CGIs, shores and shelves in BC cells, and whether the DNA methylation-based classification correlates with intrinsic subtypes, furthermore, to identify the subtype specific epigenetic markers using high-resolution methylation array.

Materials and Methods:
DNA was extracted from 31 samples of 28 BC cell lines (8 luminal, 18 basal, 2 unclassified) and 3 samples of 3 non-BC cell lines. We performed genome-wide methylation analysis using Illumina Infinium HumanMethylation450 BeadChip. We did unsupervised hierarchical clustering analysis of cell lines using top 3000 variably methylated (VM) loci among cancer cell lines. We also analyzed top 3000 VM CGI-related loci. Gene functional annotation clustering was performed using DAVID.

Results:
In top 3000 VM loci, CGIs were most frequently observed (43.0%). According to clustering analysis using top 3000 VM loci, cell lines were roughly classified into 4 clusters. There were trends that cell lines of same subtype fell into the same cluster, but not definitely. In case of clustering using top 3000 VM CGI-related loci, cell lines were clearly divided into 2 clusters, high and low methylated clusters. High methylated cluster contained almost all luminal cell lines and low methylated cluster contained most of basal cell lines and all non-BC cell lines. In low methylated cluster, cell lines of the same sub-subtype, such as Basal-like 1 and 2, were clustered closely. Gene functional annotation clustering suggested that genes related to “transcription” and “differentiation” were more frequently regulated by epigenetics.

Conclusions:
High-resolution methylation analysis revealed methylation-based clusters were concordant with intrinsic subtypes in BC cells. Transcriptional factors and differentiation-related genes could be differently regulated by epigenetics among different subtypes of BC.
Title: Meta-analysis reveal novel mechanism of bisphenol A effect on mammary gland

Xiang Gu¹, Hui Gao¹,², Danhan Wang², Abhik Bandyopadhyay¹, Qiaoxiang Dong¹,² and LuZhe Sun¹. ¹University of Texas Health Science Center, San Antonio, TX and ²Institute of Environmental Safety and Human Health, Wenzhou Medical University, Wenzhou, Zhejiang, China.

Body: Pubertal exposure to bisphenol A (BPA) has been shown to cause abnormal mammary gland development and neoplastic transformation in adults. However, the mechanism of this BPA effect still remains largely unknown. We exposed 21-day-old Balb/c mice to BPA by gavage (25 µg/kg/day) during puberty for 3 weeks. Primary mammary cells were isolated at 6 weeks, and 2 and 4 months of age and subsequently sorted into Lin-CD49f-CD24-stromal cells, Lin-CD49fhighCD24med MaSCs-enriched basal cells and Lin-CD49flowCD24high luminal progenitor-enriched cells with FACS for gene expression analysis. The Gene Ontology (GO) Enrichment Analysis shows that upon BPA treatment, the biological processes (BPs) significantly enriched in luminal compartment were related to response to organic substance and hormone stimuli at early stage (2 month old) whereas to cell cycle regulation at late stage (4 month old), consistent with published study in mammary gland morphology where BPA promoted the expansion of luminal population. However, the BPs enriched in spheres derived from basal cells (highly enriched with MaSCs) collected at late stage (4 month old) were mainly related to cell adhesion, epithelial differentiation and in stromal cells were related with vascular development for tissues collected either immediately after BPA treatment or 6 weeks later at 4-month of age. More interestingly, the Downstream Function Effects Analysis performed by Ingenuity Pathway Analysis reveal the changes in any compartments will all lead to significant activation of cancer-related downstream effects including hyperplasia, neoplasm of mammary tumor, proliferation of tumor cells and invasion of breast cancer, although there are few overlapping common genes in these compartments and conditions upon BPA treatment, indicating the different mechanism in response to BPA treatment and tumorigenesis. Network analysis revealed that the potential upstream regulators for these enriched BPs are TGFβ1, VEGF, PPARG, Estrogen/Estrogen Receptor, glucocorticoid, ERK and NOTCH signaling. Together with our recently published data, this study reveals the difference in immediate and delayed response to pubertal BPA treatment and indicates that cross-talk between several growth factor and hormonal receptor signaling pathways may contribute to the altered cellular processes by BPA, consistent with the role of BPA as an endocrine disruptor.
Title: Modeling breast cancer dormancy and re-emergence

Amanda M Clark¹, Sarah E Wheeler¹, Donald P Taylor¹,², Carissa L Young³, Venkateswaran C Pillai⁷, Donna B Stolz¹,³,⁵,⁸, Raman Venkataramanan⁷, Douglas A Lauffenburger³, Linda G Griffith³ and Alan Wells¹,²,⁵,⁶, ¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA; ³University of Pittsburgh, Pittsburgh, PA; *Massachusetts Institute of Technology, Cambridge, MA; ⁴McGowan Institute for Regenerative Medicine, University of Pittsburgh, Pittsburgh, PA; ⁵Pittsburgh VA Medical Center, VA Pittsburgh Healthcare System, Pittsburgh, PA; ⁶University of Pittsburgh, Pittsburgh, PA and ⁷University of Pittsburgh Cancer Center, University of Pittsburgh, Pittsburgh, PA.

Body: Most breast cancer (BrCa) mortality results from distant metastases. Current evidence strongly suggests that in some instances these disseminated cells remain dormant for long periods of time. Both the non-proliferative state and protective microenvironment of the metastatic niche likely contribute to the observed resistance of metastases to chemotherapies that are otherwise effective against the primary tumor. Although significant interventional progress has been made on primary tumors, the lack of relevant accessible model systems for metastases has hindered the development of therapies against this stage. To address this gap, we developed an innovative all-human 3D ex vivo hepatic microphysiological system (MPS) to faithfully reproduce human physiology and thereby facilitate the investigation of BrCa behavior in a micrometastatic niche. The liver is a major site of metastasis for carcinomas and is also the primary site of drug metabolism (activation and/or detoxification), which is a significant factor in determining efficacy and limiting toxicities of cancer therapies.

The MPS incorporates hepatocytes and nonparenchymal cells (NPC) isolated from fresh human liver resections. BrCa cells (RFP+) are seeded on day 3 and afforded time to intercalate into the hepatic tissue until treatment with chemotherapy on day 7 for 72h. Surviving BrCa cells are stimulated on day 13 with LPS/EGF and cultured through day 15. Proliferation is monitored by RFP quantification, Ki67 staining and EdU incorporation. Physiological function of the hepatic tissue is monitored throughout the experiment by protein catabolism (urea), active metabolism (glucose, CYP P450) and injury markers (AST, ALT, A1AT, fibrinogen). Luminex assays (55 analytes) were used to provide insights into the communication networks in the hepatic metastatic milieu during different stages of dormancy and progression, and identify potential metastatic biomarkers via computational approaches.

The MPS maintains the physiologic function of the hepatic niche through 15 days and BrCa cells effectively integrate into the established niche. Spontaneous dormancy is observed amongst a subpopulation of BrCa cells, indicated by the absence of Ki67 staining and EdU incorporation after 12 days of culture. Further, we demonstrate that the BrCa cells surviving chemotherapy (doxorubicin) are non-proliferating (Ki67-/EdU-). Notably, ‘re-awakening’ of the surviving non-proliferating cancer cells is observed in the presence of physiological inflammatory stressors (LPS/EGF). Luminex analyses of the milieu effluent identified signaling molecules from NPC influenced the metastatic cell fraction entering dormancy.

This MPS provides unprecedented insitters into the tumor biology of dormant micrometastases. We demonstrate the recreation of spontaneous, rather than engineered, BrCa dormancy in an all-human ex vivo hepatic MPS. Mimicking the dormancy and outgrowth observed in patients, we found that dormant breast cancer cells that are resistant to chemotherapy can be stimulated to re-emerge following an inflammatory insult. Ultimately, this MPS provides an accessible tool to identify new therapeutic strategies for metastasis during initial seeding, dormancy and re-emergence, while concurrently evaluating agent efficacy for metastasis, metabolism and dose-limiting toxicity.
Title: Mesenchymal stem cell regulated microRNAs converge on the speech gene FOXP2 and regulate breast cancer metastasis

Benjamin G Cuiffo¹, Antoine Campagne¹,², George W Bell³, Antonio Lembo⁴, Francesca Orso⁴, Evan Lien¹, Manoj K Bhasin¹, Monica Raimo⁵, Summer E Hanson⁵, Andriy Marusyk⁶, Peiman Hematti⁵, Kornelia Polyak⁶, Odette Mariani⁷, Stefano Volinia⁷, Anne Vincent-Salomon², Daniela Taverna⁴ and Antoine E Karnoub¹,⁸,⁹. ¹Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; ²Institut Curie, Paris, France; ³Whitehead Institute for BioMedical Research, Cambridge, MA; ⁴University of Turin and MBC Via Nizza, Torino, Italy; ⁵University of Wisconsin-Madison, School of Medicine and Public Health, Madison, WI; ⁶Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA; ⁷University of Ferrara, Ferrara, Italy; ⁸Harvard Stem Cell Institute, Cambridge, MA and ⁹Broad Institute of MIT and Harvard, Cambridge, MA.

Body: About 90% of breast cancer mortalities are due to the spread of breast cancer cells (BCCs) from a primary tumor to distant organs, a process known as metastasis. However, the molecular mechanisms underlying metastasis remain poorly understood. Substantial evidence now supports a major role for the tumor microenvironment (TME) in catalyzing breast cancer metastasis. Indeed, observations indicate that proximal interactions between BCCs and cells of the TME induce altered gene expression programs in BCCs, allowing for the navigation of the various steps of the metastatic cascade. Our group and others observed that breast tumors recruit mesenchymal stem cells (MSCs): multipotent fibroblasts that normally exert tissue maintenance functions. We and others have observed that physical interactions of MSCs with BCCs are sufficient to drive their metastatic dissemination in murine xenograft models, via the induction of epithelial-mesenchymal transition (EMT) and dedifferentiation into stem cell-like states (cancer stem cells, or CSCs), states tightly associated with the capacity to seed new tumors (for example in foreign tissues) and with chemotherapeutic resistance. However, the TME-induced molecular pathways regulating such mechanisms remain poorly understood.

MicroRNAs (miRNAs, miRs) are small noncoding RNAs that regulate gene expression via base-pair interactions with messenger RNAs (mRNAs), resulting in mRNA degradation or translational inhibition. Due to their ability to interact with large numbers of target mRNAs simultaneously, miRNAs are major regulators of cell identity, and thereby serve critical roles in metastasis. We performed miRnome-wide screening of MSC-stimulated BCCs to determine if TME interactions might contribute to BCC metastasis via the deregulation of miRNAs. We observed that proximal MSCs induce aberrant expression of a specific set of miRNAs in BCCs, which had not been previously implicated in breast cancer pathogenesis. These miRNAs, led by the transcriptionally co-regulated miR-199a-3p and miR-214, were sufficient to actuate the metastasis of weakly metastatic human BCCs in xenograft models. We observed that exogenous expression of the miRNAs provided BCCs with phenotypes and gene markers characteristic of CSCs, including enhanced tumor initiation capacities. Interestingly, we found that the MSC-induced miRNAs function as an interrelated network, and converge upon a common novel target: the speech associated gene FOXP2. Knockdown of FOXP2 phenocopied the metastatic phenotypes observed in MSC-induced miRNA expressing BCCs. Importantly, elevated levels of the MSC-induced miRNAs or depressed levels of FOXP2 could predict patient prognosis in the clinic. Altogether, our results incriminate FOXP2 and it’s MSC-induced miRNA regulatory network as novel determinants of breast cancer metastasis.
Title: Dual inhibition of IGF1R and insulin receptor in estrogen receptor positive and triple negative breast cancer and monitoring blockade of metastasis using novel MRI

Body: Insulin-like growth factors (IGFs) and insulin acting via the type I IGF receptor (IGF1R) and insulin receptor (IR) respectively regulate biology of estrogen positive (ER+) and triple negative (TN) breast cancer cells. In animal models, inhibition of IGF1R alone with antibodies has demonstrated significant inhibition of tumor growth and/or metastasis of several types of cancer cells. Unfortunately, the results of initial clinical trials with anti-IGF1R antibodies have been disappointing. One reason for this is that inhibition of the related IR through which insulin and IGF-II signal, may be necessary for optimal efficacy of this targeted approach. Second, there is a need to develop markers that can be used to stratify patients who may benefit from these drugs and/or monitor response to these drugs.

To examine the effectiveness of dual inhibition of IGF1R and IR, we evaluated the effects of BMS-754807, a small molecule dual tyrosine kinase inhibitor of IGF1R/IR on ER+ and TN breast cancer cells. In ER+ cells (MCF-7, T47D and ZR-75-1), BMS-754807 inhibited IGF-I, IGF-II and insulin stimulated activation of downstream PI3K and MAPK pathways, proliferation and anchorage-independent growth in vitro. BMS-754807 also blocked signaling in MCF-7 tumors and inhibited xenograft growth of MCF-7 tumors (n=10 per treatment) compared to vehicle. Interestingly, while tumor growth was suppressed over a period of five weeks, eventually the tumors displayed resistance to BMS-754807. In TN cell lines (MDA-MB-231; MDA-MB-231-LM2 and MDA-231-BoM, lung seeking and bone specific metastatic variants respectively of MDA-MB-231; and MDA-MB435A/LCC6) BMS-754807 also inhibited activation of the PI3K pathway and motility in vitro. In contrast to ER+ cells, BMS-754807 did not inhibit primary tumor growth of TN breast cancers cells injected into the mammary fat pad of mice. But BMS-754807 (50 mg/kg daily by oral gavage) inhibited metastasis of TN cells, MDA-231-LM2 and MDA-MB435A/LCC6 cells, in the orthotopic and tail vein models of metastasis compared to vehicle (n=10/group). Our data indicate that regulation of metastases and tumor growth by IGF1R can be discrete events and functional imaging to identify biological properties of metastatic breast cancer regulated by IGF1R/IR are needed to better define treatments. Therefore, we used a novel MR sequence called sweep imaging with Fourier transformation (SWIFT), where the data is acquired quasi-simultaneously with the radiofrequency pulse, to monitor response to BMS-754807. We used MDA-231-LM2 cells with the tail vein injection model of metastasis. Mice injected with breast cancer cells were treated with either vehicle or BMS-754807 and metastasis was monitored by BLI and SWIFT MRI weekly. SWIFT was sensitive in detecting inhibition of metastasis by BMS-754807.

Our results suggest that dual inhibition of IGF1R and IR is effective in blocking growth of ER+ and metastasis of TN breast cancers. However, combination of this therapeutic strategy with other agents may be necessary to prevent or delay onset of resistance. Further, noninvasive biomarkers of response to IGF1R/IR targeted drugs can be developed with SWIFT imaging.
Title: Triple negative breast cancer metastases: Protein signal transduction networks within the tumor-stromal microenvironment complement genomic analysis and stratify local versus distant metastasis

Virginia Espina¹, Maren K Levin², John D Carpten³, David W Craig³, Daniel Von Hoff³, Lance A Liotta¹ and Joyce O'Shaughnessy⁴. ¹George Mason University, Manassas, VA; ²Baylor Sammons Cancer Center, Dallas, TX; ³Translational Genomics Research Institute, Phoenix, AZ and ⁴Baylor Sammons Cancer Center, Texas Oncology, US Oncology, Dallas, TX.

Body: Background: Genomic profiling of primary TNBC may not reflect the lethal metastatic (mTNBC) lesions that constitute a selected subclone of the primary tumor. Moreover, while the stroma microenvironment of primary tumors has been the subject of study, almost nothing is known about the stromal microenvironment of metastasis. We conducted proteomic signal pathway network analysis of microdissected tumor cells and stroma from mTNBC samples for which whole genome sequencing was known. We addressed the following questions: 1) Can potentially actionable driver mutations in the metastasis be inferred from the activated/ suppressed protein signaling pathways in the tumor cells? 2) Are the tumor cell signaling pathways different between local and distant metastasis? 3) Does the proteomic signaling profile of the stroma provide strategies for stromal therapy of mTNBC?

Methods: Enriched populations of mTNBC cells and adjacent stromal cells were collected by Laser Capture Microdissection from 13 fresh frozen mTNBC samples. Signal pathway profiling of 130 protein and/or phosphoprotein endpoints were quantified by reverse phase protein arrays (RPPA). The samples represented local (regional lymph node and chest wall) (n=7) and distant (n=6) metastasis. Spearman rho correlation analysis identified pair-wise protein linakges (rho=0.8, p<0.01). Whole genome sequencing was also performed on the mTNBC samples (Craig DW. Mol Cancer Ther, 2012).

Results: We compared the protein signaling network of the tumor and matched stroma to investigate tumor-stroma crosstalk, and also to the genomic alterations (GAs) in the same tumor. GAs in mTNBC fell into two major categories: DNA repair or cell cycle/growth factor signaling. Proteomic analysis confirmed the down-regulation of endocrine (ER, AR, PR) and HER2 pathways. PhosphoJAK1/2 and phosphoHer3 were markedly down-regulated in mTNBCs, while EGFR and Her4 signaling were not. Spearman rho pairwise correlations revealed differences between local and distant metastases as well as between local and distant stroma. Cyclin D1 in locally metastatic tumor cells was linked with Autotaxin, PLCgamma and RUNX1, whereas in distant metastatic tumor cells, Cyclin D1 was linked with HIF-1alpha, phosphoJAK1, and HSP70. Growth factor signaling via phosphoEFGR was more prevalent in distant mTNBC tumor samples (322 linkages) compared to local mTNBC tumor samples (146 linkages). Distant stromal cell linkages were dominated by growth factor (phospho mTOR) and immune cell crosstalk, e.g. 21 linkages between CD63 in distant stromal samples compared to 1 CD63 linkage in local stromal cells.

Discussion: Proteomic signal pathway data can stratify metastatic lesions into functionally important groups based on a) clinical phenotype (distant versus local metastasis) and b) GA subtype (DNA repair vs growth factor signaling), thereby providing new actionable strategies for novel therapies, e.g. anti-JAK1 and anti-HSP70, and providing a means to prioritize potential driver mutations. Profiling the signal pathway network of mTNBC stroma, for the first time, provides novel strategies for targeting immune cell and mTOR pathways, for new classes of stromal therapy.
Title: Activation of oncogenic pathways by mitochondrial reprogramming in triple negative breast cancer

Jun Hyoung Park¹, Santhosh Kumar¹, Sajna Vithayathil¹, Kavisha Arora¹, Nagireddy Putluri², Efrosini Tsouko³, Taraka R Donti¹, Daniel E Frigo³, Chad J Creighton², Michael T Lewis², Arun Sreekumar², Lee-Jun Wong¹² and Benny Abraham Kaipparettu¹².¹ Baylor College of Medicine, Houston, TX and ²Dan L. Duncan Cancer Center, Baylor College of Medicine, Houston, TX.

Body: Triple negative breast cancer (TN BCa) Driver pathway is still poorly understood. Thus, it is important to identify the underlying mechanisms of triple negative breast cancer progression. Mitochondria, a semiautonomous organelle in cells, play an important role in cellular energy metabolism, free radical generation, and apoptosis. Mitochondria-nuclear crosstalk is a bidirectional pathway of communication between mitochondria and nucleus that influences many cellular and organismal activities. This crosstalk can regulate several oncogenic pathways involved in tumorigenesis. Using transmitochondrial cybrid (cybrid) technology, we generated different cybrid models under common nuclear background of TN BCa. Mitochondria from cells of different cancer potential including benign breast epithelium, moderately and highly metastatic breast cancer cell lines were used to understand cancer mitochondria regulated tumor pathways. Tumor and gene expression analysis suggested that among different cancer pathways, c-Src signaling pathway is one of the most consistently activated pathways in cybrids with TN BCa cancer mitochondria. Further analysis in parental cells and other tumor models suggested that autophosphorylation of c-Src is regulated by mitochondrial tumor characteristics. Our preliminary analysis also suggest that mitochondria targeted drugs are promising combination therapy for the management of Src-driven TN BCa. This finding is particularly important while considering the poor response rate observed after single drug therapy with Src family tyrosine kinase inhibitor Dasatinib in unselected TN BCa patients.
Title: Recurrent ESR1-CCDC170 rearrangements in an aggressive subset of estrogen-receptor positive breast cancers

Jamunarani Veeraraghavan¹, Ying Tan¹, Xi-Xi Cao¹, Jin-Ah Kim¹, Xian Wang¹, Dean P Edwards¹, Alejandro Contreras¹, Susan G Hilsenbeck¹, Eric C Chang¹, Rachel Schiff¹ and Xiao-Song Wang¹. ¹Baylor College of Medicine, Houston, TX.

Body: The crucial role of gene fusions in epithelial tumorigenesis has been recently appreciated by several milestone discoveries, but no significant recurrent translocations have yet been found in the vast majority of breast cancers that express the estrogen receptor (ER). While a majority of ER+ tumors can be effectively treated by endocrine therapy, tumors of the luminal B subtype are more aggressive and endocrine therapy-resistant. Further, the molecular blueprint of these aggressive tumors is poorly understood. Thus, characterizing the genetic alterations underlying the more aggressive forms of ER+ breast cancer is of critical significance in breast cancer management. In this study, by large-scale analyses of breast cancer transcriptome and copy number alterations, we identified recurrent rearrangements between estrogen receptor gene, ESR1 and its neighbor gene, CCDC170, which are enriched in the more aggressive and endocrine-resistant luminal-B tumors. Further screening of 200 ER+ breast tumor tissues by RT-PCR identified eight ESR1-CCDC170 positive tumors. The genomic rearrangements underlying these fusions were verified by genomic PCR and capillary sequencing. CCDC170 encodes a protein with unknown function. The observed fusion joins the 5’-untranslated region of ESR1 upstream to the coding region of CCDC170, enabling the expression of N-terminally truncated CCDC170 (∆CCDC170) under the promoter of the ESR1 gene. Consistent with the behavior of luminal B tumors, forced expression of ∆CCDC170 in ER+ breast cancer cells leads to markedly increased cell motility, invasiveness and anchorage-independent growth, and reduced endocrine sensitivity in vitro, as well as enhanced xenograft tumor formation and reduced endocrine sensitivity of the tumors in vivo. When introduced into benign breast epithelial cells, ∆CCDC170 impairs acini morphogenesis and enhances cell motility and invasiveness. Further, Knockdown of the endogenous ESR1-CCDC170 fusion variant expressed in HCC1428 cells potently inhibited cancer cell proliferation and migration, which can be rescued by forced expression of this fusion. Mechanistic studies suggest that ∆CCDC170 engages Gab1 signalosome to potentiate growth factor signaling and enhance cell motility. The augmented growth factor signaling driven by ∆CCDC170 appears to be sustained even after withdrawal of serum, and is not affected by endocrine treatment. Together, this study identified neoplastic ESR1-CCDC170 fusions in a more aggressive subset of ER+ breast cancer, which also suggests a new role of ER in breast tumorigenesis by contributing its promoter to an oncogene.

Title: TP53 alteration in morphologically benign breast tissue in patients with ER/PR negative high grade breast carcinomas: Marker for early detection of high risk patients for high grade carcinomas?

Xi Wang¹, Moritz Stolla¹, Todd S Laughlin¹, Paul G Rothberg¹, Kristin Skinner¹ and David G Hicks¹. ¹University of Rochester Medical Center, Rochester, NY.

Body: Background: TP53 alterations have been identified in approximately 20% of breast carcinomas, especially in ER/PR negative high grade carcinomas. It is believed that TP53 alteration is an early event in the carcinogenesis of high grade breast carcinomas. TP53 alteration could even be identified in morphologically "benign" appearing breast tissues. Nevertheless, the precursor lesion of high grade ductal carcinoma in situ and/or invasive carcinoma is not well recognized morphologically.

Design: We retrospectively analyzed the TP53 status of 108 cases with high grade (modified Bloom-Richardson grade 3) invasive ductal carcinoma, 51 cases with non-high grade invasive ductal carcinoma, and 50 cases with benign breast from mammoplasty. The high grade carcinomas were all estrogen receptor (ER) and progesterone receptor (PR) negative and 96.3% of them were HER-2 negative. The non-high grade carcinomas were all ER and/or PR positive, 92.2% Her2 negative. Blocks with tumor and/or benign tissue were selected from each case. Immunohistochemical stain for p53 was performed. TP53 gene sequencing was performed on selected tumors with inconclusive p53 staining. Further ER and Ki67 immunohistochemical stains were performed on the blocks with p53 positive benign tissue.

Results: Of the 108 high grade carcinomas, 48 (44%) were positive for TP53 alteration. Seventeen of the 48 (35.4%) cases also showed focal p53 staining in the adjacent benign appearing tissue. Only one case was negative for TP53 alteration in tumor but with focal p53 staining in benign tissue. Of the non-high grade carcinomas, 5 (9.8%) were positive for TP53 alteration, one of which had focal p53 staining in adjacent benign breast tissue. No p53 staining positivity was identified in the mammoplasty specimens. The p53 staining positive benign glands were ER negative, and did not show an increase in Ki67 labeling index. The morphology of these cells appeared to be slightly enlarged nuclei, with a mildly increased nuclear/cytoplasm ratio, slightly irregular nuclear contours, open chromatin, and prominent nucleoli, but still within the limits of "benign" glands.

Conclusion: TP53 is already altered in "benign" appearing breast glands in patients with high grade breast carcinomas. These glands show the same ER status as their counterpart carcinomas, but remain inactive with low Ki67 labeling index, indicating further genetic changes are needed to trigger the unlimited tumor growth and fully malignant transformation. The special morphology and p53 positivity of the "benign" appearing cells could serve as an indicator for future potential risk of TP53 positive high grade breast carcinoma.
SMAD nuclear staining patterns in inflammatory breast cancer suggest non-canonical TGFβ-signalling establishing collective, sheet-like invasion

Melike Marsan¹, Gert Van den Eynden², Patrick Neven¹, Ignace Vergote¹, Peter Vermeulen², Luc Dirix² and Steven Van Laere¹. ¹KU Leuven, Leuven, Belgium and ²Antwerp University, Antwerp, Belgium.

Introduction: Inflammatory Breast Cancer (IBC) is an aggressive and highly metastatic form of breast cancer. Recent expression profiling studies revealed IBC-specific modulation of TGFβ-signalling. In the present study, we aim to validate these findings by evaluating nuclear SMAD staining patterns.

Materials and Methods: Immunohistochemistry (IHC) was performed for SMAD2, -3, -4 and -6 on tissue sections from patients with (N=79) and without (N=133) IBC. Protocols for IHC were established on cell blocks from breast cancer cell lines with and without SMAD staining identified by western blotting on nuclear protein extracts. A staining score was assigned by multiplying the percentage of stained cancer cell nuclei by the staining intensity evaluated on a three-scale basis (1=weak, 2=intermediate, 3=strong). Expression data were subjected to unsupervised hierarchical cluster analysis (UHCA) and statistical assessment of staining differences was done using uni- and multivariate models. Additionally, we looked at the correlation between nuclear SMAD expression and gene expression in 11 patients. For each gene, we generated a spearman correlation coefficient, and selected only those genes that were positively correlated with nuclear SMAD expression in 11 patients (p<0.05).

Results: UHCA for SMAD2, -3 and -4 nuclear protein expression data identified two sample clusters downstream of the first bifurcation. IBC samples were significantly (OR=60.34, P<0.001) enriched in the cluster characterized by increased nuclear SMAD2 protein expression and absence of both nuclear SMAD3 and -4 protein expression. Univariate analysis revealed that these staining patterns are significant (all Ps<0.01). Multivariate analysis demonstrated that gain of SMAD2 nuclear expression and loss of SMAD3 nuclear expression in IBC are unrelated observations and independent of histological grade, hormone receptor expression, ErbB2 amplification and tumour stage. SMAD correlation analysis showed us that genes positively correlated with nuclear SMAD2 expression included CD44 and REL, both markers that represent crucial pathways in IBC. Interestingly, nuclear SMAD3 expression was positively correlated with ZEB1.

Discussion: In line with the expectations, our data show that TGFβ-signalling indeed differs between samples from patients with and without IBC. In addition, this study does offer novel insights on IBC biology. First, SMAD2 nuclear staining is gained in IBC in the absence of its canonical binding partners SMAD3 and -4, suggesting non-canonical TGFβ-signalling in IBC. Second, it has been shown that SMAD2 induces an invasive response program in cancer cells without affecting their epithelial morphology, while SMAD3 accounts for invasion by induction of Epithelial-to-Mesenchymal transition (EMT). Thus our results indicate that IBC cell invasion occurs in a collective, sheet-like fashion instead of EMT, which is probably responsible for the invasion of non-IBC cells.
Title: Immunohistochemical (IHC) marker discordance between primary breast cancer biopsy and recurrent cancer: Would IHC testing of the surgical breast or lymph node have altered treatment?

Michele M Gage¹, Martin Rosman², Charles Mylander², Crystal Tran², Rubie S Jackson² and Lorraine Tafra².¹Walter Reed National Military Medical Center, Bethesda, MD and ²Anne Arundel Medical Center, Annapolis, MD.

Body: Objective: Based on emerging data on tumor heterogeneity and the evolutionary branching of tumor cells, tumor cells in the lymph node may represent more virulent clones with the inherent capability of metastasis. IHC discordance from original cancer diagnosis to recurrence is documented to occur in up to 20% of cases, raising the question if characterization of these likely more virulent cells would more accurately guide treatment and predict prognosis. Our pilot study sought to determine if crucial clinical information is gained by IHC testing of the surgical breast or lymph node specimens at the time of initial surgery.

Methods: Using the cancer registry and oncology records, all invasive breast cancers diagnosed after 2001 with subsequent recurrence were identified. Cases missing all IHC data were disqualified. We then evaluated ER and HER2 of the primary cancer biopsy and recurrence biopsy to identify discordances. Those with discordances who had surgical breast and lymph node specimens available were accessed, tested, and evaluated by our breast cancer pathologist.

Results: A total of 128 recurrence cases with partial or complete primary and recurrence IHC data were identified. Of the 95 initially ER positive cases with recurrence IHC available, 13/95 had discordant, or ER negative, recurrence. Additionally, 5/27 initially ER negative tumors, 3/14 initially HER2 positive tumors, and 6/69 initially HER2 negative tumors had discordant recurrence results. In 128 cases, 27 cases were identified to have ER or HER2 discordance from primary biopsy diagnosis to recurrence. Of all cases with original surgical breast or positive lymph node specimen available, 9 markers on 7 patients were performed for our pilot study. One of seven surgical breast specimens and one of two lymph node specimens were concordant with the recurrence, but not the initial biopsy. The tested surgical breast was ER positive, while the surgical lymph node was HER2 positive, concordant to their recurrences, but discordant with initial biopsy.

Conclusion: Tumor discordance of the original cancer biopsy and recurrence is not uncommon. Our pilot study demonstrated that ER and HER2 discordance occurred in 15% and 11% of cases, respectively. Though our pilot study was limited by small sample size, we found that IHC testing of the surgical breast and lymph node specimen may provide additional clinical information and affect management. Of the two cases that had a positive lymph node available, one was HER2 positive and concordant with the recurrence. Of the seven breast specimens tested, one was ER positive and concordant with the recurrence. Had IHC testing been performed at that time of surgery, adjuvant treatment management would have been altered. Further testing of our IHC discordant recurrence patient population will be pursued to investigate the potential benefits of surgical breast and lymph node IHC testing.

Title: Promotion of lymphangiogenesis by postpartum breast tumor cells

Traci R Lyons1, Sarah A Black1, Bernard W Futscher2, Virginia F Borges1 and Pepper J Schedin1. 1University of Colorado Anschutz Medical Campus, Aurora, CO and 2Arizona Health Sciences Center, Tucson, AZ.

Body: Multiple studies report poor survival rates in postpartum women with breast cancer[1, 2]. A recent study from our group has specifically shown that incidence of recurrence and death from breast cancer is increased approximately 3-fold in postpartum patients compared to nulliparous patients[3]. We define postpartum breast cancers as those diagnosed within 5 years of birth and as a highly metastatic subset of young women’s breast cancer[4]. We have recently shown increased incidence of lymph node involvement in patients diagnosed less than 2 years postpartum and have utilized tissues from our clinical cohort to show increased lymphatic vessel density in stage II postpartum patient samples compared to nulliparous. Using xenograft and isograft murine models we have modeled postpartum breast cancer to show that postpartum tumors are larger[5], exhibit increased lymphatic vessel density, and more frequently spread to mouse lymph node and lung tissues[5] compared to tumors in nulliparous mice. In order to determine whether postpartum tumor cells specifically promote lymphangiogenesis, we utilized postpartum tumor cells ex vivo to show that lymphatic structure formation is promoted via increased postpartum tumor cell secretion of PGE2, which acts on the EP2 receptor on lymphatic endothelial cells. We have also performed expression analyses on postpartum tumor cells isolated from our xenograft model to reveal increased expression of COX-2, VEGF-C, and Semaphorin 7a; all three of these molecules have reported, and possibly interrelated, roles in promotion of lymphangiogenesis[6, 7]. Importantly, both in vivo inhibition and knockdown of COX-2 decrease postpartum tumor associated lymphangiogenesis in pre-clinical models. These results, along with our results indicating that COX-2 inhibition during the postpartum period decreases metastasis in our pre-clinical models, have led us to propose that COX-2 dependent promotion of lymphangiogenesis may facilitate, in part, metastasis of postpartum tumors.

Title: Defining the role of the kynurenine pathway in mediating anoikis resistance in triple negative breast cancer

Thomas Rogers¹, Nicholas D'Amato¹, Travis Nemkov², Michael Gordon¹, Kirk Hansen² and Jennifer Richer¹. ¹University of Colorado- Anschutz Medical Campus, Aurora, CO and ²University of Colorado-Anschutz Medical Campus.

Body: Background: Anoikis resistance is thought to be a critical trait of metastatic cancer cells, enabling them to leave the primary tumor and travel through extracellular matrix, intravasate, and survive in the vasculature or lymphatics in transit to a metastatic site. This is particularly important for the triple-negative breast cancer (TNBC) subtype, which has a peak risk of recurrence within the first three years post-diagnosis and an increased mortality rate in the first five years as compared to other subtypes. We performed global profiling of TNBC cells in attached versus forced suspension culture conditions (using poly-HEMA coated plates) for 24 hours. These data revealed that TNBC cells surviving in suspension upregulate multiple genes involved in tryptophan catabolism, also known as the kynurenine pathway (KP), including the rate limiting enzyme tryptophan 2,3,-dioxygenase (TDO) and kynureninase (KYNU). A key metabolite of this pathway has been found to activate the aryl hydrocarbon receptor (AhR), which was also up-regulated in suspended cells.

Hypothesis: We hypothesize that the ability to upregulate the kynurenine pathway (KP) facilitates TNBC cell survival in suspension and mediates the migratory/invasive potential of TNBC.

Methods: We assessed mRNA and protein levels of TDO2, KYNU and AhR by RT-qPCR and western blot. AhR luciferase reporter activity, as well as known AhR regulated genes, were measured in suspension compared to adherent conditions. TNBC cells were treated with small molecule inhibitors of AhR and TDO2. Additionally, secretion of endogenous kynurenine was measured by high performance liquid chromatography (HPLC). Purified kynurenine was added to rescue AhR activity following TDO2 inhibition. Finally, anoikis sensitivity and migratory potential were measured following pharmacological inhibition of TDO2 and AhR.

Results: Relative mRNA levels of TDO2, KYNU, and AhR increase 9, 7, and 2 fold respectively in suspended TNBC cells compared to adherent conditions (P<0.0001). Estrogen receptor positive breast cancer cells lines do not significantly upregulate these genes. AhR reporter activity (P<0.0001) and nuclear localization increase in suspended TNBC cells. Additionally, AhR reporter activity (P<0.0001) and AhR target gene expression (CYP1A1, CYP1B1: P<0.0001) decreased in TNBC cells treated either AhR antagonist (CH223191) or selective TDO2 inhibitor (680C91). Conversely, when purified kynurenine was added to TNBC cells in vitro, AhR activity increased (P<0.05). Furthermore, kynurenine secretion, as measured by HPLC, increased 2.5 fold in suspended TNBC cells and this increase in kynurenine was reduced by addition of 680C91 (P<0.0001). Finally, targeting TDO2 or AhR increased anoikis sensitivity and decreased migration of attached and suspended TNBC cells.

Conclusions: Collectively, these results suggest that the kynurenine pathway may play a critical role in metastatic TNBC. Further mechanistic studies will focus on how the kynurenine pathway is mediating these tumorigenic properties either through the de novo synthesis of NAD+ and/or activation of AhR by kynurenine. Targeting the kynurenine pathway in the clinic may provide a therapeutic strategy to reduce TNBC mortality rates.
Title: Extramedullary hematopoiesis aids initiation of cancer metastasis

Kenji Yokoi¹, Tomonori Tanei¹, Megumi Kai¹, Yuki Saito¹, Yan Ting Liu¹ and Mauro Ferrari¹. ¹Houston Methodist Research Institute, Houston, TX.

Body: Despite the recent advances in treatment of primary tumors, metastatic disease is resistant to current therapies and remains the primary cause of cancer-related death. Therefore, prevention and improved therapy of cancer metastasis are the ultimate goals of cancer research. Although tumor cells are the driving force of metastasis, novel findings suggest that the tumor microenvironment also plays a key role. Microenvironments distant from the primary tumor are primed for future metastatic growth by the recruitment of bone marrow-derived myeloid cells, creating "pre-metastatic niches", and ready for arrival of circulating cancer cells. The number of platelets is often increased in the late stage of cancer patients and experimental evidences show that platelets facilitate tumor metastasis. Within the circulatory system, platelets surround and guard tumor cells from immune elimination and produce various kinds of growth factors and cytokines to aid establishment of metastasis. But the role of platelets within the pre-metastatic niches has not yet been explored, particularly with respect to their ability to aid circulating cancer cells to arrest, survive and grow.

In our study, 4T1 murine breast cancer cells, implanted into mammary fat pad (mfp) of mice were spontaneously metastasized to the lung and liver around 6 weeks after the implantation. Interestingly, splenomegaly was found in these mice bearing 4T1 tumor in the mfp. Pathological and immunofluorescence analysis of the spleen revealed extramedullary hematopoiesis including megakaryopoiesis. Consequently, platelets accumulated into the other organs of the tumor bearing mice as early as 2 weeks after the implantation of 4T1 cells to the mfp. Interestingly, platelets accumulated into lung and liver, but not to the other major organs. To validate the effect of extramedullary hematopoiesis, 4T1 cells expressing luciferase (4T1-luc) were implanted into the mfp of normal mice or mice resected with spleen in advance. Then, development of spontaneous metastasis was monitored by luminescence imaging of the live mice. There was a significant reduction in the number of metastasis in the mice without spleen as compared to that in the normal mice, indicating crucial role of extramedullary hematopoiesis in the spleen in spontaneous metastases. Next, to evaluate biological effect of accumulated platelets into the lungs, normal mice or mice bearing 4T1 in the mfp (2 weeks after the implantation) were injected intravenously with 4T1-luc cells through tail vein. The amount of the arrested, survived and growing tumor cells in the lung was imaged and quantified using luminescence imaging of the live mice. There was a significant increase in these parameters in the mice bearing 4T1 tumor in the mfp as compared to those in the normal mice. These data strongly indicates that accumulated platelets aid circulating tumor cells to arrest, survive and grow at the lungs. Therefore platelets accumulated into the secondary sites can serve as the pre-metastatic niches. To validate these findings, mice bearing 4T1 cells in the mfp will be pre-treated with CD42 antibodies to delete circulating platelets or glycoprotein GP IIb/IIIa inhibitors which can reduce binding of activated platelets to endothelial cells.
Title: P40 suppresses breast cancer metastasis by inducing epigenetic silence of FZD10

Shaohua Qu1,2, Chang Gong1,2, Xiao-Bin Lv1,2, Bodu Liu1,2, Yan Nie1,2, Weige Tan1,2, Fengxi Su1,2, Qiang Liu1,2, Herui Yao1,3 and Erwei Song1,2. 1Guangdong Provincial Key Laboratory of Malignant Tumor Epigenetics and Gene Regulation, Medical Research Center, Sun Yat-Sen Memorial Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China; 2Breast Tumor Center, Sun Yat-sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, Guangdong, China and 3Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, Guangdong, China.

Body: P40 is a component of the SIN3A-HDAC corepressor complex that suppresses target genes transcription. It shares homology with BRMS, which suppresses metastasis of multiple types of malignancies. Although it was reported that p40 inhibits the growth of a human lung cancer cell line, the contribution of p40 in breast cancer development is not well characterized. In the present study, we found that reduced p40 in breast cancer tissues is associated with larger tumor size, higher clinical stage, aggressive distance metastasis, as well as poor patient clinical outcome. Functionally, we demonstrated that p40 suppresses migration and invasion of breast cancer cells by inhibiting epithelial-mesenchymal transition (EMT). These biological effects are mediated by epigenetic silencing of FZD10, a seven-transmembrane receptor for Wnt signaling, by facilitating the recruitment of HDAC1 to its promoter and enhancing histone H3K9 deacetylation. Consequently, p40-induced FZD10 silencing inhibits aberrant activation of Wnt3-FZD10-β-catenin signaling. Furthermore, p40 is a target of miR-106b and miR-106b upregulation leads to p40 reduction in breast cancer cells. In vivo, RNAi-mediated silencing of p40 expression promotes metastasis breast cancer xenografts in immunocompromised mice, while ectopic p40 expression inhibits metastasis. In summary, p40 provides epigenetic regulation of Wnt signaling in breast cancer cells and acts as a breast cancer metastasis suppressor. P40 down-regulation may not only serve as a prognostic factor to predict clinical outcome for breast cancer patients, but also a therapeutic target as ectopic p40 expression efficiently inhibits breast cancer metastasis by suppressing the activities of Wnt signaling.
Title: Galectin-7 increases resistance of breast cancer cells to drug-induced apoptosis and promotes tumor escape by killing T cells

Yves St-Pierre¹, Andrée-Anne Grosset¹, Marilyne Labrie¹, Donald Gagné¹, Maria-Claudia Vladoiu¹, Louis Gaboury² and Nicolas Doucet¹. ¹INRS-Institut Armand-Frappier, Laval, QC, Canada and ²Institute for Research in Immunology and Cancer, Montreal, QC, Canada.

Body: Resistance to apoptosis induced by anti-cancer drugs is a major obstacle for the treatment of aggressive forms of breast cancer. Galectin-7 was recently shown to be specifically expressed in basal-like and HER-2 positive but not in luminal subtypes of human breast cancer. Galectin-7 also increases the metastatic behavior of breast cancer cells since overexpression of this protein in poorly metastatic breast cancer cells increases their ability to metastasize to the bone and to the lung. This pro-tumoral activity of galectin-7 in breast cancer is surprising since galectin-7 had been previously associated with activation of p53 and breast cancer cells often harbor a transcriptionally inactive form of p53. We have recently reconcile this apparent contradiction by showing that elevated levels of galectin-7 in breast cancer cells occurs via a gain-of-function mechanism of mutant p53. In p53-null breast cancer cells, we have shown that C/EBPβ-2 (also known as LAP2), the most transcriptionally active of the C/EBPβ isoforms, is responsible for the upregulation of galectin-7. How galectin-7 contributes to the progression of breast cancer remains unclear. Up to now, regulation of apoptosis by intracellular galectins has been largely attributed to their ability to translocate to mitochondria, possibly following their interaction with bcl-2. Here, we report that a mutant of galectin-7 that is unable to translocate to mitochondria induces resistance of human breast cancer cells to apoptosis induced by etoposide or by hypoxia-mimicking conditions. Surprisingly, this mutant and the wild-type form of galectin-7 bind equally well to bcl-2 in vitro and in vivo. Interestingly, both forms decreases the translocation of p53 to the nucleus and reduce the expression of p21 following treatment with doxorubicin. We also found that galectin-7 was released by breast cancer cells and that recombinant galectin-7 increased apoptosis of monocytes, T CD4+ and T CD8+ cells. This suggests that galectin-7 contributes to the establishment of an immunosuppressive tumor microenvironment by killing helper and effector T cells. Taken together, these results challenges the current paradigm that mitochondrial galectins are important for resistance to apoptosis and call for a greater focus on the role of galectin-7 in breast cancer. They also indicate that targeting both cytosolic and extracellular galectin-7 could improve the efficacy of anti-cancer drugs for the treatment of aggressive forms of breast cancer.
Title: Transcription factor Fra-1 modulates the adhesive properties of breast cancer cells contributing to a metastatic phenotype

Leticia Oliveira-Ferrer¹, Melanie Kürschner¹, Vera Labitzky², Daniel Wicklein², Volkmar Müller¹, Udo Schumacher², Karin Milde-Langosch¹ and Christine Schröder². ¹University Medical Center, Hamburg, Germany and ²University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Body: Fra-1, a component of the transcription factor AP-1 family, has been found to be overexpressed in carcinomas with high metastatic potential such as in triple-negative breast cancer. The effect of Fra-1 on the morphology, motility and invasive potential of breast cancer cells has been previously described. Since tumor cell adhesion plays an essential role in the metastatic process, especially for extravasation from blood vessels, we investigated the influence of Fra-1 on breast cancer cell interactions with the endothelium.

Using the human breast cancer cell lines MCF7 (weakly invasive, estrogen receptor (ER)-positive) and MDA MB 231 (strongly invasive, ER-negative) with stable Fra-1 overexpression, we performed dynamic cell-flow adhesion assays on surfaces coated with E-selectin or with human pulmonary microvascular endothelial cells (HPMEC). Our analyses revealed increased adhesion of Fra-1 overexpressing MCF7 cells to E-selectin but also to activated endothelial cells, whereas the per se highly invasive and Fra-1-positive MDA MB 231 cell line showed enhanced cell rolling and tethering on E-selectin and endothelium-coated surfaces, but no increased firm adhesion after Fra-1 overexpression. These different behaviors correspond to an up-regulation of various adhesion-related proteins such as CD44, Integrin α5 and CEACAM6 in Fra-1 overexpressing MCF7 cells measured by microarray analysis and flow cytometry in comparison to weaker differences in the expression of adhesion molecules found in the Fra-1 overexpressing MDA MB 231 cell line. In line with these results and based on cDNA microarray data of breast cancer patients (n=175) high Fra-1 expression significantly correlates with shorter overall survival and higher rate of lung metastasis in ER-positive breast cancer patients (n=130), but has no impact on the prognosis of patients with ER-negative tumors.

Thus, in addition to its pro-invasive and pro-migratory effect, Fra-1 might influence the metastatic potential of breast cancer cells by changing the expression of adhesion molecules resulting in increased adherence to endothelial cells under flow conditions.
Body: Background: Triple-negative breast cancer (TNBC) is a highly aggressive tumor subtype associated with poor prognosis. The onset of metastasis in organs such as the lung, bone and brain is a major cause of mortality in TNBC patients. Thus, identification of novel targets for the treatment of triple-negative breast cancer is urgent for improved outcomes in patients with this disease.

Methods and Results: Here we conducted quantitative proteomic analyses in breast cancer cell lines, which include a normal, primary tumor and a metastatic tumor that were isolated from a single patient. Stable isotope labeling of amino acid in cell culture followed by LC-MS/MS analysis was performed and deregulated proteins were identified using statistical analysis. We identified for the first time that Rab1B, a member of RAS oncogene family, was down-regulated in high metastatic human breast cancer cells. In a panel of breast tumor tissues, Immunohistochemical analysis demonstrated an inverse correlation between metastatic propensity and the expression of Rab1B. Compared with primary tumors, Rab1B expression was notably decreased in lymph node metastases. Low Rab1B expression also correlated with poorer survival in triple-negative breast cancer patients. Through in vitro assays, we confirmed that silencing of Rab1B expression by RNAi in MDA-MB-231 and MDA-MB-468 breast cancer cells, can potentiate the proclivity to metastasize in Transwell assay and enhance lung colonization by tail vein injection in mice. In a reverse-complimentary approach, we determined that elevated Rab1B expression in highly metastatic breast cancer cell lines (MDA-MB-231HM and MDA-MB-231Bo) can suppress the ability of invasion and metastasis in vitro and in vivo. Mechanistically, we establish that the metastatic behavior strongly correlates with increased phosphorylated Smad3 levels and overexpression of TGF-β type I receptor (TβRI). Conversely, restoration of Rab1B can inhibit the activation of this pathway in MDA-MB-231HM and MDA-MB-231Bo cells.

Conclusion: By utilizing a series of mammary tumor cell lines, animal models, and clinically sourced tissues, we demonstrate that Rab1B acts as a metastasis suppressor in triple-negative breast cancer through regulating TGF-β/Smad signaling pathway.
Title: Effects of JAK pathway inhibition in pre-clinical models of breast cancer bone marrow metastases

Alessia Bottos¹, Jason Gill¹, Thomas Radimerski², Alexandar Tzankov³, Aleksandra Wodnar-Filipowicz¹ and Nancy E Hynes¹.
¹Friedrich Miescher Institute for BioMedical Research, Basel, Switzerland; ²Novartis Institutes for BioMedical Research, Basel, Switzerland and ³University Hospital Basel, Basel, Switzerland.

Body: Bone marrow (BM) metastases are an important problem in metastatic breast cancer. Metastatic-relapse occurs even decades after the first diagnosis and can show different clinical features compared to the primary disease. The cross-talk between cancer cells and the microenvironment influences tumor behaviour and impinges on therapeutic efficiency.

To uncover new targets for the inhibition of BM metastases, we performed a transcriptional analysis of BM stromal cells using in-vivo models of breast cancer bone metastases. We identified IL6, and its downstream JAK kinases pathway, as major up-regulated signals in the bone stroma of tumor-bearing mice. Moreover, we found that a significant proportion of BM metastases from breast cancer patient biopsies are positive for pSTAT3 staining, attesting to activation of JAK-STAT signaling. These results provide a rational to investigate the therapeutic potential of a JAK inhibition in bone metastases. We evaluated the effect of two JAK inhibitors: the BSK805, a JAK2 inhibitor, and ruxolitinib a JAK1-JAK2 inhibitor currently in clinical trials for metastatic breast cancer. In pre-clinical models of breast cancer metastases (the triple negative MDA-MB231 SCP1833 and the ER+ EO771), treatment with the JAK inhibitors decreased pSTAT3 signaling in the bone, but surprisingly increased metastatic tumor burden.

Considering the importance of the JAK-STAT pathway as a therapeutic target, we are investigating the possible bystander effects of blocking JAK kinases. Analysis of the BM stroma showed that JAK inhibition decreased TRAP+ osteoclasts and affected the mesenchymal compartment, with a significant increase in the BM fat compartment in tumor-bearing animals. The reasons for and the consequences of these changes in the bone stroma are under investigation. As the JAK-STAT signaling pathway is also a key regulator of the hematopoietic compartment, we are studying how JAK inhibitors influence the immune response in tumor bearing mice. Further dissection of the immunomodulatory effect of JAK inhibition and how this influences tumor dissemination and expansion is warranted.
Title: Melatonin's inhibitory effect on breast cancer metastasis mediated by ROCK-1

Debora C Zuccari¹, Thaiz F Borin¹, Ali S Arbab³, Lívia C Ferreira², Marina G Moschetta¹, Gustavo R Martins¹, Larissa B Maschio², Vanessa A Fabri¹ and Verena B Coimbra¹. ¹Faculdade de Medicina de São José do Rio Preto, FAMERP, Sao Jose do Rio Preto, São Paulo, Brazil; ²Universidade Estadual Paulista (UNESP/IBILCE), Sao Jose do Rio Preto, São Paulo, Brazil and ³Cancer Cener, Georgia Regents University, Augusta, GA.

Body: The metastasis occurrence, an important prognostic factor, depends on peculiarities such as cellular invasiveness and cell migration, mechanisms controlled by regulatory and effector molecules such as Rho-associated kinase protein (ROCK-1). An increased expression of this protein promotes tumor growth and metastasis, a mechanism which can be restricted by the use of the effector’s inhibitors. Melatonin, a hormone secreted by the pineal gland, has shown oncostatic action and anti-metastatic effects and can modulate the ROCK-1 expression. The objective of this study was to investigate the anti-metastatic response mediated by ROCK-1 and through the action of melatonin and its specific inhibitor (Y27632) in vitro and in vivo breast cancer models. Cells from metastatic (MDA-MB-231) and non-metastatic (MCF-7) breast cancer lines were treated with melatonin and Y27632. Cell viability was verified by MTT assay, cell migration/invasion assays in Boyden chamber, ROCK-1 protein and gene expression by western blot and quantitative real time PCR, respectively. In addition, the in vivo metastasis study was performed using female athymic nude mice induced by injection of 2x10⁵ MDA-MB-231 viable cells by tail vein for lung metastasis and by intracardiac for bone metastasis, during 3 weeks. The animals were treated with melatonin and Y27632 for 2 weeks. The metastasis developments were evaluated by single photon emission computed tomography (SPECT). Treatment with melatonin reduced cell viability and migration of both cell lines (p<0.05). The use of melatonin and Y27632, in association or not, decreased the ROCK-1 protein expression in metastatic cells, not significantly altering its expression in the non-metastatic line (p>0.05). An statistically significant reduction of ROCK-1 gene expression was observed in all treatment groups (p<0.05). ROCK-1 downexpression was more efficient in the group with associated treatments for both lines (p < 0.05). In vivo SPECT images showed multiple foci in the lungs (on Tc-99-tetrofomin images) and in the vertebrae (on Tc-99-MDP images). The numbers of “hot” spots were significantly higher in lung metastasis of control animals compared to treated groups. Semi quantitative analysis showed significantly lower activity in animal lungs that received treatment (p<0.05). The bone metastasis did not show difference between control and treatment groups. Melatonin and Y27632 are effective drugs of metastatic breast cancer in vitro treatment, confirming their effects in decreasing cell viability, invasion, migration and protein expression of ROCK-1 in these cells. In vivo, melatonin and Y27632 treatments seem to be effective reducing lung metastasis but not bone metastasis. Melatonin, in particular, appears to be more effective when combined to ROCK-1 inhibitor.

Title: N-glycosylation changes in tumour cells are associated with vascular invasion and metastasis in breast cancer patients

Karin Milde-Langosch¹, Tosca Karius¹, Dina Schütze¹, Harriet Wikman², Isabell Witzel¹, Leticia Oliveira-Ferrer¹, Volkmar Müller¹ and Udo Schumacher³. ¹Hamburg University Medical School, Hamburg, Germany; ²Hamburg University Medical School, Institute of Tumor Biology, Hamburg, Germany and ³Hamburg University Medical School, Institute of Anatomy and Experimental Morphology, Hamburg, Germany.

Background: In a recent study based on cDNA microarray data of breast cancer patients, we could show that the mRNA expression of some glycosylation enzymes involved in synthesis and trimming of N-glycans is significantly associated with metastasis and recurrence in breast cancer patients suggesting an important role of N-glycosylation in tumour progression (Milde-Langosch et al., Breast Cancer Res Treat 2014). The aim of the present study was to further investigate this issue on a protein and glycoprotein level (1.) by western blot analysis of selected glycosylation enzymes and (2.) by lectin histochemistry using lectins which bind to O- and/or N-glycans.

Methods: In order to confirm the role of two selected glycosylation enzymes, ribophorin (RPN1) and mannosidase (MAN1A1) on protein level, we analyzed their expression in a cohort of 196 breast cancer samples by western blot analysis. In addition, we studied tumour cell binding of various lectins, which recognize diverse O- or N-glycans (UEA1, HPA, PNA, GNA, PHA-L), using a tissue microarray with up to 293 evaluable breast cancer samples. These results were correlated with recurrence-free survival (RFS) and overall survival (OS) and data on vascular and lymphatic invasion.

Results: By western blot analysis, the negative prognostic significance of ribophorin (RPN1), a key enzyme of N-glycosylation, was corroborated on a protein level. For MAN1A1 which is involved in trimming of N-glycan structures, two isoforms with different molecular weight could be detected on western blots, showing contradictory associations with OS. Protein levels of RPN1 and total MAN1A1 showed significant correlations to the respective mRNA expression data. By lectin histochemistry, we found significant correlations of lectin binding to lymph node metastasis, vascular invasion and lymphangiosis in breast cancer samples. Binding of PHA-L and GNA (binding to N-glycans) and PNA (binding to O- and N-glycans) was significantly associated with vascular invasion, whereas PNA and PHA-L binding correlated with lymph node involvement. In addition, PNA and HPA reactivity was associated with microscopically detected lymphangiosis. PNA binding also correlated with shorter RFS and OS.

Conclusion: While the role of O-glycans in breast cancer metastasis has already been described, our data point to an additional strong impact of N-glycosylation on metastasis and progression of mammary carcinomas.
Title: Investigating the role of Duffy antigen receptor for chemokines (DARC) isoforms in breast cancer metastasis

Rupali Hire¹, Andrea Walens¹, Brianna Bennett¹, Kauthar Mumin¹, Hailey Campbell¹, Michael Lou², Michele Monteil², Elizabeth Howerth³ and Melissa Davis¹. ¹University of Georgia, Athens, GA; ²Health Sciences Campus, University of Georgia, Athens, GA and ³College of Veterinary Medicine, University of Georgia, Athens, GA.

Body: Duffy Antigen Receptor for chemokines (DARC) is known to regulate the biological activities of chemokines. It has been implicated in the progression of various diseases including different types of cancer, affecting survival, proliferation and metastasis. Genetic variants in the DARC genes are strongly associated with African ancestry and are linked to malaria resistance. There are at least two isoforms of DARC, which have not been appreciably investigated in these contexts, that may have differing chemokine activity functions. To fill this knowledge gap, we have been characterizing the impact of DARC gene variants on DARC isoform expression in specific tissue types in order to define relationships between the polymorphic DARC and its effect as an immune regulator in breast cancers. We hypothesize that DARC variants, which are known to impact expression of the gene on erythrocytes, also are associated with functional activity related to DARC’s control of metastatic potential in breast cancer. Specifically, we have determined that one DARC polymorphism which is well defined in ancestral groups (i.e. Duffy null - rs2814778; -541T>C) is associated with differential expression of DARC isoforms in epithelial cell types, including lymphoblast and breast tissues.

We investigated the erythroid silencing Duffy Null allele of DARC using DNA sequencing and quantitated DARC isoform expression by real time PCR in breast cancer cell lines, ancestral cell lines and breast cancer tumor tissues. We will show that DARC isoforms have significantly variant expression among ancestral groups that is associated with the Duffy Null allele. We will also show that certain types of breast tumors have variable DARC expression that is also associated with this genotype. Additionally, we visualized the subcellular localization of DARC and known interacting chemokines breast cancer cells with IHC and IF confocal microscopy.

Specifically, our results indicate breast tumors differentially express DARC in which may be affecting the chemokine pool and immune response within the tumor and its microenvironment. In our Hapmap ancestral populations, all DARC genotypes expressed the gene in lymphoblast, with significantly different levels of isoforms among African, African American and European individuals. Breast cancer cells also show different levels of specific DARC isoform mRNA levels and distinct levels and patterns of binding chemokines, related to tumor subtype origins (i.e. ER status).

Based on these findings we conclude that DARC isoforms have differential expression levels in breast cancer cells within tumor and non-tumor regions that may drive both pro and anti tumorigenic events with varying chemokine binding or localizations during tumorigenesis of specific breast cancer subtypes. Different levels of isoforms in epithelial cells may contribute to its essential function as atypical chemokine receptor. We hypothesize that immune responses in breast cancer patients with Duffy Null genotypes will differ and may express more severe metastasis due to altered epithelial regulation of alternate DARC isoforms.
Title: Pathway activation mapping of metastatic breast cancer identifies potential organ-specific signatures: Implications for patient stratification to targeted treatment

Mariaelena Pierobon¹, Stephen P Anthony², K Alex Reeder¹, Nicholas J Robert³, Donald W Northfelt⁴, Mohammad Jahanzeb⁵, Linda Vocila⁶, Julia D Wulfkuhle¹, Bryant Dunetz⁷, Lance A Liotta¹ and Emanuel F Petricoin¹. ¹George Mason University, Manassas, VA; ²Evergreen Hematology & Oncology, Spokane, WA; ³Virginia Cancer Specialists, Fairfax, VA; ⁴Mayo Clinic, Scottsdale, AZ; ⁵University of Miami, Deerfield Beach, FL; ⁶Translational Drug Development, Scottsdale, AZ and ⁷Sideout Foundation, Fairfax, VA.

Body: Background: The development of distant metastases is the strongest prognostic factor associated with cancer mortality. Customization of treatment based on molecular profiling of a patient’s primary tumor has yielded promising results and has opened a new paradigm for treating patients with advanced disease. Nevertheless profiling the primary tumor may not reflect the actionable molecular drivers of the metastatic lesions. In the last few years a large number of genomic and proteomic studies have demonstrated that at the molecular level metastatic lesions significantly differ from matched primary tumors. The impact of metastasis site organ microenvironments on breast cancer primary tumors has been only partially explored. Since most targeted therapies work by modulating aberrantly-activated protein kinase signaling, the aim of this study was to utilize reverse phase protein arrays (RPPA) to explore whether metastatic lesions derived from different patients, but invading the same host target organ showed similarities in their signaling architecture and presented with organ-specific targetable signatures. Methods: Snap frozen material collected from 14 metastatic breast cancer patients enrolled in a prospective phase II trial (“Side Out II”) were used for this analysis. Sites of metastasis were: liver (n=7), skin/chest wall (n=4), and lung (n=3). All samples were subjected to Laser Capture Microdissection (LCM) and RPPA to measure the activation/phosphorylation levels of 12 FDA approved drug targets and linked substrates. Results: Among the 7 patients with liver metastases, p70S6K, c-Abl, ERK 1/2 were highly phosphorylated in 5 cases (71.4%), ErbB2/HER2 in 4 cases (57.1%), and AKT in 3 cases (42.8%). On the contrary, of the 4 patients with skin/chest wall lesions 3 showed high activation of ErbB2/HER2, ErbB3/HER3, and ERK 1/2 (75.0%) and 2 of EGFR (50.0%). Of note, none of the skin/chest wall lesions showed activation of AKT and only 1 case presented with activated p70S6K (25.0%). Lung metastasis showed an overall low activation of all 12 analytes measured. Discussion: Although this data is based on a relatively small number of samples and needs further validation, our initial analysis revealed potentially important trends that could have an impact in the prioritization and selection of targeted agents for metastatic breast cancer trials. We found that the distribution of the 12 FDA approved drug targets and downstream substrates varies between different metastatic sites. Thus, the emergent hypothesis from this work is that breast cancer patients with liver metastases may be more susceptible to AKT-mTOR directed targeted therapeutics and patients with skin/chest wall metastasis may benefit from therapies that target EGFR and/or downstream ERK signaling.
Title: Modeling breast cancer metastasis in the mouse via measurement of circulating tumor cells

Jennifer L Gorman¹, Michael Parsons¹, Eldad Zacksenhaus², Sean Egan³, Martin Chang⁴ and Jim R Woodgett¹.
¹Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; ²Toronto General Research Institute – University Health Network, Toronto, ON, Canada; ³Program in Developmental and Stem Cell Biology, The Hospital for Sick Children, Toronto, ON, Canada and ⁴Mount Sinai Hospital, Toronto, ON, Canada.

Body: Objectives: Advances in the detection of circulating tumor cells (CTC) in the blood of metastatic breast cancer patients have indicated that patients with greater than 5 CTC/7.5mL of blood have poorer prognosis; however, little is known about the biology of these cells and what characteristics are critical for breast tumor cell dissemination. We are developing and evaluating several mouse models of breast cancer to characterize important markers that distinguish CTCs from other cell types in the blood as well as to assess whether silencing of various metastasis supporting genes leads to reductions in CTC counts and formation of metastatic tumors.

Methods: This study involves two separate approaches to characterize CTCs. The first involves xenograft models using human breast cancer cells injected into the fat pad of immunocompromised mice. These cells are tagged with both mCherry, for detection in blood, and luciferase, to track metastatic spread of the primary tumor cells to other sites via intravital imaging. Blood was collected from tumor bearing mice at end point, processed and stained for characterized CTC markers. The second approach involves endogenous mouse models to characterize CTC counts and relevant markers in a variety of metastatic and non-metastatic murine breast cancer models using negative depletion to remove contaminating normal and hematopoietic cells. In both approaches CTCs have been assessed using the Imagestream by Amnis.

Results: Initial xenograft experiments with MDA-MB-231 cells injected into the mouse mammary gland fat pad revealed a low concentration of mCherry+/cytokeratin+/Hoechst+/CD45- cells in the blood of mice without confirmed metastatic dissemination. Pilot studies on endogenous tumor models have demonstrated the utility of our negative depletion approach to remove contaminating hematopoietic cells as well as the detection of a population of EpCAM+/Hoechst+/CD45- cells.

Conclusions: Initial experiments have provided feasibility for detailed characterization of mouse CTCs, which will be presented. This work complements our study being carried out on characterizing CTCs in metastatic breast cancer patients. Increasing understanding of the biology of circulating tumor cells and relating their characteristics to those of both the primary and metastatic tumors may reveal mediators common and functionally important to all 3 tumor cell populations and may therefore serve as better targets for treatments that are effective against both the primary and metastatic tumors.
Title: SSA, a novel sulindac sulfide derivative, inhibits tumor cell growth and invasion in breast cancer

Bin Yi¹, Xiangling Feng¹, Hong Chang¹, Ruixia Ma¹, Xiaoguo Zhang¹, Gary A Piazza¹ and Yaguang Xi¹. ¹University of South Alabama, Mitchell Cancer Institute, Mobile, AL.

Body: Nonsteroidal anti-inflammatory drugs (NSAIDs), such as sulindac sulfide (SS), have been reported for striking chemopreventive activities in various types of human malignances, including breast cancer. However, the toxicities related to cyclooxygenase (COX) inhibition resulting in suppression of physiologically important prostaglandins limit their clinical use for chemoprevention in human cancer. We recently developed a novel amine derivative of SS named as SSA, which lacks inhibitory effect on COX-1 or -2, yet shows 10 times greater suppressive effect than SS on growth of a panel of breast cells. Moreover, SSA treatment at sub-cytotoxic concentration (4µM) for 36 hr can significantly inhibit both migration and invasion of highly aggressive breast tumor MDA-MB-231 cells. To understand the molecular mechanism accounting for this activity, we examined 4 oncogenic miRNAs, including mir-17-92, mir-9, mir-10b, and mir-21 that were previously reported by our group to be associated with SS anti-invasive activity in breast and colorectal cancer. We found SSA could significantly down-regulate these miRNAs; whereas their forced expression was able to counteract the anti-invasive activity of SSA in MDA-MB-231 cells. These results imply that significance of SSA with non-COX inhibitory properties in suppression of tumor cell invasion could provide novel insights into development of safer and more effective strategies for prevention of breast cancer progression and metastasis. In addition, after inducing mobility of non-invasive breast MCF-7 cells by using TGF-β1, we treated these invading cells with SSA and found that their mobility was significantly decreased. These results support anti-invasive activity of SSA in human breast cancer cells and inhibition of TGF-β1 as well as oncogenic miRNAs may be responsible for the mechanistic basis by which SSA prevents breast tumor cell invasion.

This study is supported by an American Cancer Society Research Scholar Grant (RSG-13-265-01-RMC) and NIH/NCI R21 Grants (5R21CA160280 and 1R21CA182754) to Yaguang Xi.
Title: Global analysis of the transcriptome in matched primary and metastatic tumours defines ER specific gene alterations

Damir Vareslija¹, Ailis Fagan¹, Jean McBryan¹, Patrick Buckley², Michael Farrell², Arnold DK Hill¹ and Leonie Young¹. ¹Royal College of Surgeons in Ireland, Dublin, Ireland and ²Neuropathology, Beaumont Hospital, Dublin, Ireland.

Body: The incidence of brain metastasis (BM) among women with metastatic breast cancer (MBC) is currently on the rise, and it is estimated that between 10-30% of patients diagnosed with breast cancer may also develop BM (Weil 2005). BM is considered a late complication in the clinical setting and is an infrequent occurrence even in mice studies that readily metastasise to other organs (Valiente 2014). While pre-menopausal status and negative estrogen receptor (ER) status are seen as main risk factors (Gil-Gil 2013), it is now recognised that BM is emerging as an increasing clinical problem across the various MBC subtypes. BM patients have very poor overall survival and as a result it is crucial to identify the factors that promote the survival and adaptation of breast cancer cells to allow them to colonise distant sites such as the brain. The ability to predict the BM potential could be of great clinical importance and in this study we decided to investigate the mechanisms underlying BM across the various MBC subtypes.

To our surprise, in a cohort of breast cancer patients we found a comparable number of ER positive and ER negative BM. We established that ER positive patients (n=10) had a substantially longer disease latency period (median disease free survival (DFS) 36 months, range 8-85 months) in comparison to ER negative patients (n=8, HER2 positive, n=2, triple negative, n=6), (median DFS 24 months, range 9-60 months). To understand and elucidate the gene alterations required for successful colonisation of the brain we undertook RNAseq of sequential primary and brain metastatic tumours from ER positive (n=4) and ER negative (n=3) breast cancer patients. Significant elevations in gene expression were observed in the brain metastatic tumours in comparison to the matched primary. Though a large degree of patient heterogeneity was observed, common ER-specific metastatic pathways were identified.

This study highlights the requirement of unique gene sets for the colonisation to the brain and that functional characterisation of the differentially expressed genes will enable the identification of novel molecular targets for prevention and treatment of breast cancer BM.
Title: Neutrophil elastase modulates breast cancer progression by fostering collective cell detachment and tumor emboli dissemination

Caterina Marchio¹, Laura Annaratone¹, Davide Balmativola¹, Maria Stella Scalzo², Stefania Bolla², Silvia Grasso³, Isabella Russo³, Federica Fusella³, Luigia Macrì², Mara Brancaccio³, Paola Defilippi² and Anna Sapino¹. ¹University of Turin, Turin, Italy; ²Azienda Ospedaliera Città della Salute e della Scienza, Turin, Italy and ³University of Turin, Italy.

Body: Proteases constitute a large family of enzymes involved in several processes, including degradation and remodeling of the extracellular matrix to drive dissemination of cancer cells into adjacent tissue. Within this large family, the serine protease neutrophil elastase (NE) has been proven clinically meaningful in breast cancer. Indeed, high levels of NE correlate with poor outcome and endocrine resistance in breast cancer patients.

In an experimental model it has been demonstrated that estrogen receptor positive (ER+) MCF7 breast cancer cells grow in suspension as 3D-spheroids in NE-addicted medium, thus resembling the micropapillae of a human breast cancer characterized by high propensity to metastasize, i.e. the micropapillary carcinoma. We hypothesized that NE may produce disarrangement of tumor cell adhesion to the substrate fostering neoplastic lymphovascular invasion (LVI) and metastasis. ER+/E-Cadherin (E-CAD+)/HER2- (MCF7, T-47D, ZR-75-1), ER+/E-CAD+/HER2+ (BT-474), ER-/E-CAD+/HER2+ (SK-BR-3) and ER-/E-CAD-/HER2- (MDA-MB-231) cells were grown with serine proteases (NE, cathepsin-G), hyaluronidase and collagenase. NE and cathepsin-G led to 3D-spheroid formation of ER+/E-CAD+ cells only. In 3D-spheroids from MCF7 cells grown with NE the luminal Epithelial Membrane Antigen (EMA) lined the external border of cell clusters, which faced cancer associated fibroblasts in co-cultures experiments, thus recapitulating the inverted polarity of MPCs. MCF7 3D-spheroids were tamoxifen resistant. Injection of NE in tumors of MCF7 cells in SCID mice triggered neoplastic cluster detachment, micropapillae, vascular emboli similar to 3D-spheroids and metastases. In a cohort of human breast carcinomas with LVI the MCF7-3D-spheroid-alike pattern was the most prevalent in tumor emboli. Immunohistochemical NE expression was mainly detected in polymorphous neutrophilic granulocytes (PMNs) within vessels and in the stroma and PMNs were significantly higher in breast carcinomas with LVI. In fully developed metastases within lymph-nodes, which reverted the EMA expression as in the primary tumor, no NE+ PMNs were observed. Our results may explain why high levels of NE negatively act on patient prognosis by creating a favorable environment for breast cancer invasion and metastasis.
Title: Expression of S100A14 promotes cancer cell invasion and metastasis and is associated with poor prognosis in breast cancer

Takashi Sugino¹, Mizuko Tanaka², Takuma Oishi¹ and Takashi Nakajima¹. ¹Shizuoka Cancer Center Hospital, Nagaizumi-cho, Sunto-Gun, Shizuoka Prefecture, Japan and ²Fukushima Medical University School of Medicine, Fukushima, Fukushima Prefecture, Japan.

Body: Introduction: Identifying key molecules involved in cancer metastasis is important in anticancer drug discovery. To identify such molecules, we used a dual approach involving: 1) gene screening and in vivo confirmation of metastasis-promoting molecules using a mouse mammary tumor model; and 2) functional and clinicopathological analyses of the candidate molecules in a human cancer. The products of several candidate genes promoted metastasis of mouse mammary tumors. A protein designated S100A14 promoted metastasis in the mouse model and was found to be associated with poor prognosis in human breast cancer patients.

Methods and Results: 1) Identification of metastasis-related molecules: We established two highly metastatic cell lines, 66Lu10 and 66HM, which formed multiple metastatic colonies in general organs, from MCH66 mouse mammary tumor cells. Two low-metastasis cell lines, 66C8 and 66LM1, were also established. DNA microarray analysis was used to identify candidate metastasis-related genes based on differential expression in 66Lu10 and 66HM cells compared with 66C8 and 66LM1. An in vivo metastasis assay in which the highly metastatic cells were transfected with gene-specific siRNAs and orthotopically inoculated into mice was performed to confirm the metastasis-promoting activity of the candidate genes. Several novel molecules that promoted metastasis in the mouse model were identified, including S100A14. 2) Significance of S100A14 in human cancer: Analysis of S100A14 protein expression in various human cancer cell lines and tissues revealed that S100A14 expression is upregulated in breast cancer. Functional analysis using MCF7 and SK-BR-3 human breast cancer cells showed that S100A14 colocalizes with F-actin on the cell membrane at cell-cell attachment sites and on focal adhesions at the leading edge. Immunoprecipitation analysis also demonstrated an interaction between S100A14 and F-actin. Boyden chamber and wound-healing assays showed that S100A14 knockdown substantially suppresses the invasive activity of both cell lines. Immunohistochemical analysis of archival specimens of primary tumors from 167 breast cancer patients showed strong membranous staining of S100A14 (53%). Elevated expression of this protein was significantly associated with younger age (<60 years), ER-negative status, HER2-positive status, and poorer prognosis (P=0.0002).

Conclusions: Using our mouse mammary tumor model for identifying metastasis-related genes, we identified S100A14 as a strong candidate metastasis-promoting molecule in vivo. Functional analyses using human breast cancer cell lines indicated that S100A14 promotes invasive activity via interaction with cytoskeletal components. Upregulated expression of S100A14 is associated with poor prognosis in breast cancer patients. Therefore, S100A14 is a potential prognostic biomarker and breast cancer therapeutic target.
Title: The role of cytoplasmic polyadenylation element binding protein-2 in breast cancer

Asma Hasan¹, Mousumi Majumder¹ and Peeyush K Lala¹. ¹University of Western Ontario, London, ON, Canada.

Body: **Background:** We had shown that over-expression of the inflammation-associated enzyme cyclo-oxygenase (COX)-2 promotes breast cancer progression and metastasis and sustains stem-like cells (SLC), believed to evade traditional therapy and promote tumor reoccurrence. Stable transfection of the COX-2 gene into COX-2–, HER-2–, non-metastatic human MCF-7 breast cancer cell line (named MCF-7-COX-2) led to a highly aggressive phenotype *in vitro*, where we observed epithelial-mesenchymal transition, increased migration, invasion, clonogenic tumorsphere forming ability (surrogate of SLC) and expression of SLC marker ALDH. Furthermore, we observed an increase in the tumorigenic and metastatic capacity of the cells in immuno-compromised mice *in vivo*. Combined gene expression and microRNA (miRNA) micro-array analysis of MCF-7 and MCF-7-COX-2 cells revealed COX-2 induced up-regulation of two miRNAs, miR-526b and miR-655, and down-regulation of their common gene target, cytoplasmic polyadenylation element binding protein (CPEB)-2. While both miRNAs were found to be oncogenic in functional assays, the function of CPEB-2 in breast cancer remains untested. **Hypothesis:** miR-526b and miR-655 down-regulate CPEB-2 to promote breast cancer cell aggressiveness and the SLC phenotype. **Approaches & Results:** (1) To test if expression levels of COX-2 and CPEB-2 are inversely related, we measured both gene and protein expression in multiple COX-2 disparate breast cancer cell lines. (2) We also tested if there is an inverse relationship between miRNA expression and the expression levels of their target gene CPEB-2. We found that high COX-2/miRNA expressing cell lines such as MDA-MB-231 and MCF-7-COX-2 had significantly lower expression of CPEB-2 than MCF-7 cells (low COX-2/low miRNA). (3) To test the functional effects of CPEB-2 gene manipulation *in vitro* and *in vivo*, we knocked down CPEB-2 in CPEB-2-high MCF-7 cell line. MCF-7-CPEB-2-KD cells were found to be more migratory and invasive than control cells in transwell assays. Ongoing studies are to test (a) whether there is a cause and effect relationship between the expression of the miRNAs and CPEB-2 expression, that is, whether knocking down or knocking in the miRNAs respectively up-regulates and down-regulates CPEB-2 expression; and (b) whether CPEB-2 expression is lower in breast cancer tissues than in adjacent non-tumor tissues, and inversely correlated with the miRNAs in breast cancer tissues. **Conclusion and Significance:** If CPEB-2 is proven to be tumor suppressor, these oncogenic miRNAs and putatively anti-oncogenic CPEB-2 may serve as potential biomarkers in personalizing breast cancer therapy with COX-2 inhibitors as adjuvant. (Supported by funds of the OICR to PKL. AH and MM are CaRTT/TBCRU scholars).
Title: FOXC1/FOXA1 transcriptional balance in breast cancer: From acquisition of mesenchymal and stem cell traits to occult lymph node independent breast cancer metastasis

Partha S Ray¹,², Tor W Jensen², Tania Ray³, Omid Gholamalamdari⁴, Connie Y Tsai², Bomy Kim², Rohit Bhargava⁵ and K V Prasanth⁴.
¹University of Illinois College of Medicine, Urbana, IL; ²Carle BioMedical Research Center, Urbana, IL; ³Oracle Biosciences, Champaign, IL; ⁴University of Illinois at Urbana Champaign, Urbana, IL and ⁵University of Illinois at Urbana Champaign, Urbana, IL.

Body: Background: Distant metastatic spread of cancer cells to other organs from the primary site of origin currently constitutes the most significant contributor to cancer-related morbidity and mortality. Epithelial-to-mesenchymal transition (EMT) is a biologic transformation of cancer cells from a non-migratory phenotype to a migratory one, and is thought to initiate the metastatic cascade in cancer. EMT has also been reported to trigger acquisition of stem cell traits in breast cancer. Transcription factor (TF) Forkhead box C1 (FOXC1), strongly associated with the basal-like and claudin-low breast cancer molecular subtypes, is a powerful EMT inducer and is also a marker of stem/progenitor cells. In contrast, TF forkhead box A1 (FOXA1), strongly associated with luminal subtypes, is an EMT repressor and a luminal differentiation marker, thus seemingly exerting reciprocally opposite transcriptional effects to that of FOXC1. We hypothesized that effective EMT program activation status in breast cancer might be better predicted by examining the expression ratio of an EMT inducer and EMT repressor, such as FOXC1/FOXA1, theoretically being more reflective of net transcriptional effect than either component alone. Methods: Herein we utilize RNA-Seq profiling of the HRAS-transformed MCF10A cell series, a well characterized and widely accepted in vitro model of breast cancer progression and metastasis, to correlate measured FOXC1/FOXA1 ratios to dynamic shifts in EMT marker expression in 3D matrigel cultures and to stem cell traits observed in primary and secondary mammosphere suspension cultures. We further test the ability of the FOXC1/FOXA1 expression ratio to predict lymph node independent breast cancer metastasis and death in independent human breast cancer gene expression datasets. Results: RNA-Seq and qRT-PCR profiling confirmed progressive increase in FOXC1/FOXA1 ratio to correlate with a progressive loss of E-cadherin expression and synchronous gain of EMT markers N-cadherin, Fibronectin, and Vimentin. FOXC1/FOXA1 ratio was found to be directly proportional to mammosphere formation efficiency, a surrogate indicator of stem cell enrichment. In patients without any evidence of nodal metastasis, elevated FOXC1/FOXA1 ratio was associated with significantly decreased 10 year Overall Survival (HR 2.58;95%CI 1.39 to 4.80, p = 0.003, 295 patient Van de Vijver dataset), 10 year Disease-specific Survival (HR 1.74;95%CI 1.16 to 2.61, p = 0.008,1992 patient Curtis dataset) and predicted the development of lung metastasis. Conclusion: Elevated FOXC1/FOXA1 expression ratio indicates EMT program activation in breast cancer, and predicts the associated occurrence of lymph-node-independent distant metastasis and death in human patients. These findings may allow for the early (pre-symptomatic) diagnosis of clinically occult (node negative) metastasis by using the FOXC1/FOXA1 ratio as a biomarker of metastasis and permit institution of appropriate therapy earlier than currently possible. The current study improves our understanding of EMT and highlights the importance of future studies geared towards unraveling mechanisms involved in regulating FOXC1 and FOXA1 expression in breast cancer.
Title: Role of astrocyte in the triple-negative breast cancer brain metastatic growth

Ling Wang¹, Stephanie M Cossette¹, Ling Zhong¹, Kevin R Rarick¹, Jill Gershan¹, Michael B Dwinell¹, David R Harder¹ and Ramani Ramchandran¹. 'Medical College of Wisconsin, Milwaukee, WI.

Body: Patients with triple-negative breast cancer (TNBC) have the worst outcome among breast cancer patients due to high propensity for brain metastatic spread. So far, no targeted therapies have been developed to help prevent brain metastasis in patients with TNBC. Therefore, it is critical to address the gap in knowledge because it will allow for targeting of triple-negative cells, thereby preventing brain metastasis formation in these patients. The outcome of metastatic process depends on interactions of metastatic cells with the specific organ microenvironment. In the brain microenvironment, astrocytes are one of the first cell types in the blood-brain barrier that brain-invading cancer cells encounter post extravasation. Reactive astrocytes have been found in close proximity to individual cancer cells in BM, which suggests the importance of astrocytes in tumor BM formation. To investigate the role of astrocyte in TNBC brain metastasis formation, we sequentially passaged TNBC MDA-MB-231 cells in primary rat neonatal or adult astrocyte culture media, and then the astrocyte media conditioned tumor cells were used for further experiments. Our results showed that cultured astrocyte-secreted factor(s) induced a correlated morphological and functional alteration of MDA-MB-231 cells, which endowed the tumor cell with a more invasive phenotype and enhanced their ability of metastatic growth in the brain. Furthermore, analysis of the gene-expression profile of the conditioned MDA-MB-231 cells showed dramatic alteration of some tumor related genes, and the tumor genetic alteration happened at transcriptional level in several critical tumor genes, such as SPP1 and Angptl4. Although reactive astrocytes surrounding tumor brain metastases has been observed, our data provides direct evidence that astrocyte secreted factors support TNBC cell brain metastatic growth. The underlying mechanisms for how astrocyte secreted factors induce tumor genetic alterations that contribute to TNBC to grow in the brain are actively being investigated by us currently with the purpose to target the astrocyte secreted factor(s) and the key corresponding tumor cell genetic alterations as clinical targets for therapy of TNBC brain metastasis.
Activated thrombin activatable fibrinolysis inhibitor is a novel anti-metastatic factor in breast cancer

Zainab A Bazzi1, Deborah Rudy1, Lisa A Porter1, Dora Cavallo-Medved1 and Michael B Boffa1. 1University of Windsor, Windsor, ON, Canada.

**Body:** Thrombin activatable fibrinolysis inhibitor (TAFI) is a plasma zymogen initially known for its role in attenuating fibrinolysis. Activated TAFI (TAFIa) is formed through proteolytic cleavage by thrombin, plasmin or, its most effective activator, thrombin in complex with the endothelial cofactor thrombomodulin (TM). TAFIa is a carboxypeptidase, which acts by cleaving carboxyl terminal lysine and arginine residues from protein and peptide substrates, including plasminogen binding sites on cell surface receptors. Carboxyl terminal lysine residues play a vital role in accelerating plasminogen activation to plasmin on the cell surface. Plasmin has many critical functions including cleaving components of the extracellular matrix (ECM), which enhances invasion and migration of cancer cells. In addition, plasmin can activate matrix metalloproteinases (MMPs), which also play a role in degrading the ECM. Furthermore, the expression of TM in tumours is inversely correlated to metastasis. Studies have shown that the anti-metastatic effects of TM result from its ability to bind thrombin. Given that the thrombin/TM complex is responsible for the activation of TAFI, the anti-metastatic effects of TM may be modulated by TAFIa. We therefore hypothesize that the activation of TAFI on the cell surface inhibits plasminogen activation and decreases breast cancer cell invasion and migration. Expression of TAFI and TM were assessed in breast cancer cells with varying degrees of metastatic potential. Although TAFI mRNA levels did not correlate with malignancy, TM mRNA levels were found to be inversely correlated with breast cancer cell malignancy. Moreover, cell invasion and migration of MDA-MB-231 and SUM149 cells were assessed upon treatment with potato tuber carboxypeptidase inhibitor (PTCI), which is a specific inhibitor of TAFIa. Inhibition of TAFIa resulted in a significant increase in cell invasion and migration of both cell lines. Cell invasion and migration of MDA-MB-231 and SUM149 cells were also assessed upon treatment with TM. Treatment with TM significantly decreased cell invasion and migration of both MDA-MB-231 and SUM149 cells. Additionally, experiments using a fluorogenic collagen substrate showed an increase in extracellular collagen cleavage after PTCI treatment, using both MDA-MB-231 and SUM149 cells. Furthermore, the ability of TAFIa to inhibit pericellular plasminogen activation was evaluated. Plasminogen activation was significantly decreased on the surface of MDA-MB-231 and SUM149 cells following treatment with various concentrations of TAFIa. Taken together, these results indicate a vital role for TAFIa in regulating pericellular plasminogen activation and ultimately ECM proteolysis. Enhancement of TAFI activation in the breast cancer tumour microenvironment may be a therapeutic strategy to inhibit invasion and prevent metastasis of breast cancer cells.
Title: CIP4 promotes triple-negative breast cancer metastasis and is associated with poor prognosis

Andrew WB Craig¹, Otto LD Cerquiera², Fernando A Soares³ and Eduardo M Reis². ¹Queen's University, Kingston, ON, Canada; ²Instituto de Química – Universidade de São Paulo, São Paulo, Brazil and ³A.C.Camargo Cancer Center, São Paulo, Brazil.

Body: Epidermal growth factor receptor (EGFR) and Src kinase pathways are key drivers of triple-negative breast cancer (TNBC) cell invasion and tumor metastasis. Cdc42-interacting protein-4 (CIP4) is an adaptor protein targeted by these pathways, and has been identified as a key regulator of cancer cell motility. Here, we address the role of CIP4 in TNBC metastasis in vivo, and CIP4 expression profiling in human breast cancer patients. Using an inducible CIP4 knock-down (KD) system in human TNBC cell lines, we observed effects of CIP4 silencing on EGFR signaling to Akt and MAPK pathways. Although CIP4 KD cells were capable of growth in spheroid assays, we observed a significant reduction in invasion of the surrounding extracellular matrix compared to control cells. Profiling of conditioned media from these cell lines revealed a role for CIP4 in promoting expression of matrix metalloproteinase-2 (MMP-2). CIP4 silencing in mammary orthotopic xenograft assays using both human and rat breast cancer models, led to defects in lung metastases. Profiling CIP4 expression in primary human breast tumors by immunohistochemistry revealed high CIP4 levels in myoepithelial cells and within subtypes with high risk of metastasis (HER2, TNBC). In a cohort of 245 patients with invasive ductal carcinoma, patients with high CIP4 levels were more at risk of developing metastases. Together, these findings implicate CIP4 in promoting breast cancer metastasis in mice, and identifies a link between CIP4 expression levels and risk of metastasis in breast cancer patients.
Title: A breast angiosarcoma treated by bilateral mastectomy in a patient who had undergone to arm amputation for Stewart Treves syndrome following breast conserving surgery: Case report

Esat Namal¹, Merve Tokocin², Emel Gokmen¹, Ozgul Pamukcu³, Serdar Altunay⁴, Osman Bilgin Gulcicek² and Atilla Celik².
¹Bagcilar Education and Research Hospital, Bagcilar, Istanbul, Turkey; ²Bagcilar Education and Research Hospital, Bagcilar, Istanbul, Turkey; ³Sisli Etfal Education and Research Hospital, Sisli, Istanbul and ⁴Bagcilar Education and Research Hospital, Bagcilar, Istanbul.

Body: INTRODUCTION: Stewart Treves Syndrome is a rare disease who is undergone breast conserving surgery or total mastectomy accompanied by curettage of axillary lymph nodes. There is a risk for chronic subclinical edema and angiosarcoma secondary to radiotherapy. We represent a case that we have performed bilateral mastectomy and right arm amputation to a 61 year old woman who had undergone to breast conserving surgery for invasive ductal carcinoma ten years a go.

CASE: A 61 year old woman who had undergone to breast conserving surgery and axillary curettage for invasive ductal carcinoma 10 years ago, had also received radiotherapy, chemotherapy and hormonotherapy. The patient who was given a couple of different treatments with the complaints of swelling and erythema in her arm, was diagnosed as CD34+ lymphangiosarcoma by punch biopsy performed because of the unresponsiveness of other treatments. In her PET-CT scan, there was not seen any involvement except primary tumor at right elbow. Disarticulation to the right upper extremity was performed. One month after the operation, there was appeared erythema, swelling and bruise also on the skin of her right breast and biopsies were obtained from the lesions. Mastectomy was considered for the patient who was histopathologically diagnosed as CD31+, Fli 1 + angiosarcoma. Because of the fact that there was also macromastia in her left breast, not to cause a postural distortion and changes in balance bilateral mastectomy was planned as the patient agreed.

After the operation as the tumor was reported as high grade angiosarcoma (Ki67>20) histopathologically, Paclitaxel 80mg/m2 D1,D8, D15 was administered every 28 days. In her imaging studies after four cycles of chemotherapy, there was no signs demonstrate relapse or metastasis. There was not seen adverse effectss except grade 1 fatigue and grade 1 neurotoxicity.

RESULTS: While the risk for angiosarcoma following the breast conserving surgery is %0.14, recent studies shows an increase in this precentage. After radiotherapy, along with chronic subclinical edema cytokines such as endothelial growth factor can induce proliferation of lymphatic vessels and fibrosis which can be resulted in angiosarcoma. On the other hand, it is suggested that the lymph dissection creates a predisposition to angiosarcoma. Breast conversing surgery is equal to mastectomy for early breast cancers and the numbers of this operation increase at the present. Therefore, there is a possibility of an increase in the risk of angiosarcoma development. Because of the fact that early detection of Stewart Treves Syndrome is very important, the skin changes must be well observed in the patients who had undergone axillary dissection and receive radiotherapy.
Fatty acid binding protein 5 promotes metastatic potential of triple negative breast cancer

Catherine A Powell¹, Mohd W Nasser¹, Jacob C Wochna¹, Konstantin Shilo¹, Xiaoli Zhang¹ and Ramesh K Ganju¹. ¹Ohio State University, Columbus, OH.

Body: Triple negative breast cancer (TNBC) is an aggressive subtype of breast cancer that has a poor prognosis for patients, not only due to its aggressive nature, but also due to the lack of effective therapeutic strategies. High mortality is associated with metastasis of the primary TNBC. We analyzed the role of fatty acid binding protein 5 (FABP5), an intracellular fatty acid transport protein, in aggressive breast cancers, especially TNBC. FABP5 expression was analyzed in a tumor microarray (TMA) containing 423 breast cancer patient samples and found that FABP5 expression is associated with tumor grade, triple negative status, and disease-free survival. Next, a mechanistic approach was taken and found that FABP5 knockdown TNBC cell lines express lesser EGFR protein compared to control, and upon EGFR activation express less phospho-FAK and phospho-Pyk2. We found that EGFR was not down regulated at the transcriptional level in FABP5 knockout cells. Further analysis indicated the role for Cbl, an E3 ubiquitin-protein ligase, as a potential mechanistic target for the down-regulation of EGFR protein in FABP5 knockdown cell lines. EGFR is over-expressed in aggressive breast cancers, especially TNBC. Though EGFR is highly expressed in aggressive subtypes of breast cancer, targeted therapeutic strategies have not been successful in clinic. EGFR has been shown to be involved in distant metastasis in aggressive breast cancers. We found a correlation between FABP5 and EGFR expression and metastasis-free survival using publically available datasets from The Cancer Genome Atlas. We next studied the functional consequence of FABP5 knockdown in TNBC cell lines. We showed that EGF-induced FABP5 knockdown cells migrated less compared to control. Additionally, FABP5 knockdown cells were significantly less able to migrate into a wound in response to EGF stimulation. EGF-induced cell attachment of FABP5 knockdown cells is significantly decreased compared to control. Our findings suggest FABP5 modulates metastatic potential of TNBC through alterations in EGFR expression and downstream migratory signaling molecules.
Title: Signaling consequences and rational therapeutic combinations with glutaminase inhibitor, CB-839, in basal breast cancer

Jennifer B Dennison¹, Zhenlin Ju¹ and Mills B Gordon¹. ¹UT MD Anderson Cancer Center, Houston, TX.

Body: Purpose: Proliferation rates of basal breast cancers are dependent on glutamine metabolism as previously demonstrated by glutamine withdrawal or glutaminase inhibition by CB-839 in cell line models. Early and late adaptive signaling and metabolic responses to glutamine stress may enable cells to proliferate or evade cell death. We hypothesized that inhibition of these pathways would be synergistic in combination with glutaminase inhibition by CB-839.

Methods: Protein signaling responses in HCC1806 cells (basal A breast cancer) were quantified using reverse phase protein arrays (RPPA) at early (4 h) and late (24 h) time points in response to low glucose or low glutamine concentrations as well as treatment with CB-839, a selective glutaminase inhibitor. Signaling pathways evaluated included mTORC1/2, PI3K/AKT, MAPK, and AMPK. ADP and ATP were quantified by ion exchange chromatography. Drug combinations predicted by RPPA were evaluated at therapeutically relevant concentrations using proliferation or apoptosis assays after 72 h of continuous treatment.

Results: In agreement with previous reports of glutamine withdrawal, low glutamine and glutaminase inhibition resulted in inhibition of proliferation and early inhibition of mTORC1 signaling including pmTOR, pP70S6K, p4EBP1, and pS6. In contrast, for cells incubated in low glucose, proliferation and mTOR signaling were maintained at early time points despite robust pAMPK/pACC signaling and increased ADP/ATP ratios (2-orders of magnitude higher than baseline); mTOR signaling was only inhibited after 24 h when ATP concentrations were reduced. Bioenergetic stress as detected by pAMPK and pACC was not observed with glutaminase inhibition – ATP concentrations were increased by CB-839 treatment. Importantly, 2-deoxyglucose, a compound used to reduce ATP levels and activate AMPK signaling, was antagonistic in combination with CB-839. In contrast, hydroxychloroquine, an inhibitor of autophagy activated by mTOR inhibition, was synergistic with CB-839. Consistent with mTORC1-mediated negative feedback loops, CB-839 treatment also increased AKT and ERK signaling. Combinations of CB-839 with AKT or MEK inhibitors (AZD5363 and GSK1120212B) were at synergistic and additive, respectively, for cell proliferation. The MEK inhibitor in combination with CB-839 resulted in supra-additive effects using apoptosis as an endpoint.

Conclusion: Glutaminase inhibition by CB-839 acutely inhibited mTORC1 signaling independently of AMPK signaling in HCC1806 cells. MEK and AKT signaling increased, likely in response to negative feedback loops with mTORC1. Combinatorial approaches with CB-839 targeting these compensation pathways resulted in increased responses supporting further preclinical and clinical studies.
Title: Metformin blocks de novo synthesis of cholesterol in triple negative breast cancer cells

Ann D Thor¹, Zeying Fan¹, Reema Wahdan-Alaswad¹, Steve M Anderson¹, Jennifer K Richer¹ and Susan M Edgerton¹. ¹University of Colorado Anschutz Medical Campus, Aurora, CO.

Body: Background: Metabolic shifts in cancer and stem cells are well recognized (the so called Warburg Effect). Tumor cells frequently demonstrate alterations in lipid metabolism. The anti-diabetic drug metformin has been shown to have broad anti-cancer activity, reducing both the incidence and mortality of several types of cancer. Metformin inhibits pro-oncogenic cell signaling and metabolic pathways, and has demonstrated unique anti-stem cell activity. We have reported that metformin is particularly active against triple negative (TN) breast cancer cells, inducing S phase arrest and apoptosis. Metformin down regulates de novo fatty acid synthesis, significantly reducing fatty acid synthase (FASN) and FASN protein expression. Mechanistically, these shifts appear secondary to a metformin associated up regulation of miR-193a, which directly targets the FASN 3'UTR (In press, Wahdan-Alaswad et al, Hormones and Cancer).

Cancer cells require high cholesterol for membrane synthesis, rigidity, the formation of lipid rafts (membrane regions which organize critical receptor/signaling molecules including the epidermal growth factor receptor (EGFR)), and to provide precursor molecules for hormones and sterols. While de novo cholesterol biosynthesis and high systemic cholesterol levels have been associated with an increase in breast cancer risk and a worse prognosis for women with the disease, clinical studies of statins (drugs to inhibit the mevalonate synthesis pathway and thus block cholesterol synthesis) have shown mixed results. Silvente-Poirot S et al have suggested that the contradictory effects of anti-cholesterol strategies may be due to the complexity of the genes and enzymes controlling the "sterolome" (Science, 2014).

Results: The effects of metformin on de novo cholesterol biosynthesis in the TN breast cancer cells, MDA-MB-231 and MDA-MB-468, were studied using expression profiling and miRNA microarrays. Metformin treatment for 24 h down regulated the expression of 21 genes encoding enzymes in the cholesterol biosynthesis pathway at high levels (up to 9 fold), which has been confirmed by qRT-PCR. Metformin treatment for 6 h also resulted in the upregulation of 17 miRNA, which are predicted to control many of the down regulated genes. These data suggest a post-translational inhibition of cholesterol biosynthesis, similar to what we have reported for fatty acid biosynthesis (see above). The down regulated enzymes include critical steps in complex cholesterol biosynthesis pathway occurring in the cytosol, endoplasmic reticulum and the nuclear envelope. Western blots have confirmed that miRNA 141 and miR192 reversed the metformin induced reduction in p-MEK1/2, p-Akt and pMAPK.

Conclusions: Metformin regulates cancer cells by multiple pathways including reduction in cell growth, increases in apoptosis and alterations in cellular metabolism. The effects on the cholesterol pathway are both extensive and affect multiple downstream pathways including EGFR, Akt, and MAPK.

Partial funding was provided by the Susan G. Komen Foundation.
Title: Targeting lactate metabolism as a novel therapeutic target in platinum-resistant triple negative breast cancer (TNBC)

Narumi Harada¹, Vidhya Varghese¹, Lingmin Xie¹ and Laura M Kenny¹. ¹Imperial College London, United Kingdom.

Body: Introduction TNBC is a heterogeneous disease and is often associated with expression of a stem cell signature (CD44⁺, CD24⁻). Recently platinum agents have been shown to improve the pathological response rates in the neo-adjuvant setting; however a significant proportion of patients with TNBC will relapse. The study objective was to evaluate the potential of targeting glycolysis, mitochondrial function and lactate metabolism in platinum resistant TNBC cell lines.

Methods Stem cell signature and glycolytic phenotyping: CD44 and CD24 antibodies were used to measure the percentage of stem cells in each of the cell lines using flow cytometry(FACS). Protein expression of hexokinase, Glut1 transporter, lactate dehydrogenase A/B(LDHA and LDHB), and monocarboxylic transporter 1 and 4 (MCT1 and MCT4) was determined in MCF7(control), MDA-MB231, MDA-MB468, and HCC38 cells. Proliferation and apoptosis assays: IC50s for platinum, metformin, and MCT1 inhibitor AR-C155858, Tocris (MCT1I) were calculated by the sulforhodamine B (SRB) assay. Propidium iodide and AnnexinV staining intensity used to measure apoptosis by FACS. Metabolic analysis: The change in lactate and glucose levels in culture media post-treatment with metformin and MCT1I was quantified by 1H NMR. Intracellular lactate and ATP concentrations were determined by lactate(BioVision) and ATP determination assays(Invitrogen). Mitochondrial membrane potential and Reactive oxygen species (ROS) were measured by MitoTracker Red and MitoSOX Red. 2NBDG was used to assess cell glucose uptake. Combination index SRBs: Cells were treated with increasing concentrations of MCT1I and metformin for 72h. The combination index values were calculated using CalcuSyn® software.

Results MDA-MB231 and HCC38 cells were resistant to cisplatin and associated with a stem cell signature (CD44⁺, CD24⁻) which was not detected in the other cell lines. MCT1 was highly expressed in HCC38 cells but not at all in MDA-MB231. In contrast, MCT4 was abundantly expressed MDA-MB231 but minimally in HCC38 cells. In these two cell lines, only MDA-MB231 was sensitive to metformin which reduced ATP production, induced ROS generation, and increased the percentage of apoptotic cells. HCC38 also produced ROS, but ATP production and apoptosis were unaffected. HCC38 cells were more sensitive to MCT1I than other cells, which was associated with increased intracellular lactate. The NMR data showed significant increases in lactate in culture media following treatment with metformin in MDA-MB231 and HCC38. Only HCC38 had increased 2NBDG uptake and reduced of glucose levels in culture medium by metformin. Metformin significantly enhanced the anticancer efficacy of MCT1I in HCC38 cells, as a synergistic effect of the two agents was observed across the range of different concentrations; whilst an antagonistic effect was shown in MDA-MB231 cells with almost all concentrations.

Conclusions Targeting lactate metabolism selectively inhibits a platinum-resistant stem cell population of TNBC, this effect is enhanced when combined with metformin. The inhibition of glycolysis and lactate metabolism may represent a new therapeutic strategy for this population and warrants further study.

Title: Metabolic state of reprogrammed breast cancer stem cells

Erina Vlashi1, Chann Lagadec1, Patricia Frohnen1, Yazeed Alhiyari1 and Frank Pajonk1. 1University of California, Los Angeles, CA.

Body: Purpose: In general, tumor cells display a more glycolytic phenotype compared to the corresponding normal tissue. However, it is becoming increasingly clear that tumors are composed of a heterogeneous population of cells. Breast cancers are organized in a hierarchical manner, with the breast cancer stem cells (BCSCs) at the top of the hierarchy. Here, we demonstrate that breast cancer cells are heterogeneous in their metabolic phenotypes, with the breast cancer stem cells displaying a reliance on oxidative phosphorylation, while the more differentiated progeny display a glycolytic phenotype. The metabolic state of radiation-induced reprogramming of BCSCs was also investigated.

Methods: Luminal, basal, and claudin-low breast cancer cell lines were propagated as mammospheres enriched in BCSCs. Lactate production, glucose consumption and ATP content was compared with differentiated cultures. A metabolic flux analyzer was used to determine the oxygen consumption, extracellular acidification rates, maximal mitochondria capacity and mitochondrial proton leak. The effect of radiation treatment of the metabolic phenotype of each cell population was also determined.

Results: BCSCs consume more glucose, produce less lactate and have higher ATP content compared to their differentiated progeny. BCSCs have higher maximum mitochondrial capacity and mitochondrial proton leak compared to their differentiated progeny. Radiation treatment enhances the higher energetic state of the BCSCs, while decreasing mitochondrial proton leak.

Conclusions: Our study indicated that BCSCs reside in a distinct metabolic state compared to their differentiated progeny, and appear to depend more on oxidative phosphorylation. Interfering with the metabolic requirements of BCSCs may prevent radiation-induced reprogramming of breast cancer cells during radiation therapy, thus improving treatment outcome.
Title: An association between obesity and more aggressive breast cancer subtype

Saranya Chumsri, Paula Rosenblatt, Candace Mainor, Gauri Sabnis, Olga Goloubeva and Angela H Brodie. University of Maryland Greenebaum Cancer Center, Baltimore, MD.

Body: Background: Obesity has become epidemic in the United States with over one third of the adult population being obese. The incidence of obesity is even higher among African American population with slightly more than half of the population being obese. Elevated body mass index (BMI) has been associated with an increased risk of breast cancer in postmenopausal women. This is believed to be due to higher levels of estrogens, inflammation, and insulin. Given that adipose tissue is the major source of estrogen production via the aromatization of androgens into estrogens in postmenopausal women, there is a concern that obese women may have inadequate estrogen suppression with a fixed dose of aromatase inhibitors (AIs). Multiple recent retrospective analyses of large phase III adjuvant endocrine therapy trials demonstrated that obese patients had worse outcome when treated with AIs. However, it remains unclear whether there is also a difference in the tumor subtype among normal weight, overweight, and obese patients.

Method: A retrospective review of breast cancer cases diagnosed from July 2008 and August 2011 was performed. Patient characteristics, BMI, and pathologic findings were collected. An immunohistochemistry (IHC)-based molecular subtypes was assigned based on St. Gallen criteria: Luminal A (ER/PR+, HER2- and Ki67 \leq 14%), Luminal B (ER/PR+, HER2+ or Ki67 > 14% or grade 3), HER2 enriched (ER/PR-, HER2+), and Triple negative breast cancer (TNBC; ER/PR-, HER2-). Using the WHO classification, normal weight was defined as BMI < 25, overweight BMI 25-30, and obese BMI \geq 30.

Result: 143 patients were included in the analysis. The median age was 55 years. The majorities of our patients were African American (63%) and presented with early stage disease (stage I 29%, stage II 45%, stage III 22%, and stage IV 5%). IHC-based molecular subtypes were luminal A 20%, luminal B 48%, HER2 enriched 7%, and TNBC 25%. 21% were normal weight, 30% overweight and 49% obese. As shown in the table below, comparing between normal weight, overweight, and obese patients, there is a possible association between tumor subtype and BMI status (p = 0.03). The majority of TNBC patients (94.4%) were overweight or obese. Specifically, there is significantly more aggressive luminal B subtype compared to luminal A (52.86% vs. 15.71%) among obese patients (p = 0.017). We further evaluated the effect of obesity and tumor growth in xenograft model of MCF7Ca. Comparing between obese mice fed with high fat vs. lean mice fed with chow diet, there is a significant increase in tumor growth among obese mice (p = 0.04) which corresponds to the high proliferation index measured by Ki67 seen in patients with luminal B subtype.

Conclusion: Our study suggests that obesity may provide a microenvironment that support and accelerate tumor growth, particularly in luminal breast cancer subtypes. Furthermore, the poor outcome seen in obese patients may also be in part due to more aggressive tumor subtype.
The role of nitric oxide synthase uncoupling in breast tumor cell maintenance

Christopher S Rabender¹ and Ross B Mikkelsen¹. ¹Virginia Commonwealth University, Richmond, VA.

Body: Nitric oxide (NO) has been demonstrated to activate both proliferative pathways as well as pro-apoptotic pathways in breast carcinogenesis. One explanation that may account for these apparently conflicting conclusions is the dual activity of nitric oxide synthase (NOS). The unstated assumption in most all studies with tumors is that NOS synthesizes NO from arginine; however, as is well documented in vasculature literature, NOS can have two activities: NO or O2-/ONOO- synthesis. A requirement of NOS for the production of NO is the cofactor tetrahydrobiopterin (BH4) and in inflammatory environments BH4 can undergo direct oxidation to dihydrobiopterin (BH2). It has been demonstrated that the product of NOS catalytic activity is dictated by the ratio of BH4:BH2, as the enzyme has equal affinity for both. When BH4 is bound in the active site, NO is the product; whereas, O2- predominates when BH2 is bound. Given the inflammatory microenvironment of breast tumors, our studies set out to examine NO signaling in breast tumor cells from a new perspective of NOS dysregulation. We examined BH4:BH2 in MCF-7 and MDA231 breast tumor cells both in tissue culture and as flank xenografts as well as in spontaneously derived breast tumors (MMTV-neu) and determined that the BH4:BH2 is significantly reduced over what we measure in normal tissue. This results in NOS uncoupling and leads to decreased NO signaling and increased pro-inflammatory, pro-survival, signaling as a result of the increased generation of ROS/RNS from uncoupled NOS activity. We are able to increase the BH4:BH2 and recouple NOS through the exogenous BH4 precursor, sepiapterin, both in vitro and in vivo, reducing ROS/RNS and reestablishing NO signaling through cGMP protein associated kinase. Reduction of ROS/RNS results in the reduced activity of two major constitutively active transcription factors in breast cancer cells, NFκB and STAT3. In MCF-7 and MDA231 cells we found that increased NO-dependent PKG signaling led to tumor cell toxicity mediated by downregulation of β-catenin expression and TCF-4 promoter activity. Downregulation of β-catenin led to increased protein levels of p21 in MCF-7 and p27 in MDA 231cells, ultimately resulting in cell death in vitro and in vivo as measured by ex vivo clonogenic assay and 18F-deoxyglucose positron emission tomography. These results along with our results demonstrating decreased spontaneously developing mammary carcinogenesis in MMTV-neu mice suggest that there is potential for BH4 as a therapeutic agent.

Title: A novel pharmacodynamic assay to measure glutaminase inhibition following oral administration of CB-839 in triple negative breast cancer biopsies

Andy MacKinnon¹, Mark Bennett¹, Ethan Emberley¹, Mathew Gross¹, Julie Janes¹, Evan Lewis¹, Alison Pan¹, Mirna Rodriguez¹, Peter Shwonek¹, Taotao Wang¹, Jinfu Yang¹, Frances Zhao¹ and Francesco Parlati¹. ¹Calithera Biosciences, South San Francisco, CA.

Body: Triple negative breast cancer (TNBC) cell lines are highly dependent on glutamine (Gln) for growth and survival. A critical step in Gln utilization is its conversion to glutamate (Glu) by the mitochondrial enzyme glutaminase (GLS). CB-839 is a potent inhibitor of GLS that has anti-proliferative activity in TNBC cell lines and antitumor activity in TNBC xenograft models (Gross et al., Mol. Cancer Ther. 13:890). Across a panel of breast cancer cell lines derived from both receptor positive and TNBC tumors, sensitivity to CB-839 was associated with (i) elevated GLS expression, (ii) elevated GLS activity, and (iii) the TNBC subtype. Importantly, many of the determinants of CB-839 sensitivity in cell lines are also present in primary tumor samples, including high mRNA and protein expression of GLS and a high Glu to Gln ratio in TNBC tumors as compared to receptor positive tumors. These observations motivate the Phase 1 clinical study of CB-839 in TNBC patients. To aid in the selection of a recommended Phase 2 dose, we sought to develop a pharmacodynamic (PD) assay to directly measure the GLS activity in breast tumor lysates in order to determine the extent of GLS inhibition in tumor biopsies from CB-839 treated patients.

To develop a robust PD assay, we first identified conditions that maintain the GLS:CB-839 inhibitory complex during preparation of lysates from CB-839 treated samples. High concentrations of KCl (150 mM) and low concentrations of K-phosphate (15 mM) in the lysis buffer, as well as maintaining the lysate at a low temperature stabilized the inhibited complex. Following gel filtration of the lysate to remove unbound CB-839 and exchange the buffer, GLS activity was immediately measured with a coupled enzyme assay. The GLS activity measured at this step reflects the residual activity present in a sample that was exposed to CB-839. To quantify the amount of total GLS present in the sample, we incubated the same lysate for 3 hours at room temperature under conditions of low KCl and high phosphate to allow the the GLS:CB-839 complex to fully dissociate prior to measuring activity. This assay format allows quantitation of the % GLS inhibition from a single tumor lysate sample and eliminates the requirement for multiple biopsies as well as any assay variability due to tumor heterogeneity.

We utilized this tumor PD assay to determine the plasma drug levels required for maximal tumor GLS inhibition in a preclinical TNBC model. Mice bearing HCC1806 TNBC tumors were first treated with a range of CB-839 doses. Four hours after oral administration, a 10 mg/kg dose of CB-839 resulted in >90% inhibition of tumor GLS. CB-839 plasma concentrations of 100 nM corresponded to 50% inhibition of tumor GLS, while maximal inhibition occurred at plasma concentrations ≥300 nM. In xenograft studies, maximal anti-tumor efficacy was achieved with BID dosing at 200 mg/kg, a dose and schedule that resulted in trough plasma levels of CB-839 of ≥300 nM and sustained GLS inhibition in tumors. As part of an ongoing Phase 1 trial, this assay will be utilized to monitor tumor PD responses in TNBC patients undergoing treatment.
**Title:** Reduction of HER2-associated lipogenic phenotype by docosahexaenoic acid (DHA) induces apoptosis in breast tumor cells harboring HER2 overexpression

Graziela R Ravacci¹, Maria M Brentani¹, William Festuccia², Tharcisio Tortelli¹, Angela F Waitzberg³ and Dan L Waitzberg¹.

¹University of São Paulo â–“ FMUSP, Faculty of Medicine, São Paulo, SP, Brazil; ²Institute of BioMedical Science â–“ University of São Paulo â–“ ICB/USP, São Paulo, SP, Brazil and ³Federal University of São Paulo (UNIFESP), São Paulo, SP, Brazil.

**Body:** The lipogenic phenotype is associated with oncogenic transformation and malignancy in the cancer setting. Our hypothesis is that the oncogenic nature of lipogenesis depends on the expression of HER2 oncogene, and its modulation by docosahexaenoic acid-DHA, might induce apoptosis in breast tumor cells with HER2 overexpression. To evaluate if the lipogenic phenotype might be induced by HER2 overexpression, we used a oncogenic transformation cell model in which, cells were engineered to overexpress HER-2 receptor (HB4aC5.2), but are identical to their parental strain (HB4a) in all other aspects, permitting an specific analysis of enhanced HER-2 effects. Toward this end the lipogenesis profiling was characterized, evaluating several molecular features, including synthesis (FASN), uptake(CD36), transport(FABP4) and storage(DGAT) of FA by RT-PCR and lipogenic regulatory pathways (mTOR, DEPTOR, SREBP1 and PPARγ) in both cells. Lipogenic contribution to lipid rafts formation, which is necessary to HER2 receptor location and activation in the cell membrane, was evaluated by gas chromatography and confocal microscopy. The influence of HER2 overexpression and lipogenic phenotype on proteins activated by HER-2 (AKT, ERK1/2 and FASN) was analyzed by western blot. Next, HB4a and HB4aC5.2 cells were treated, alone or in combination, with DHA, Trastuzumab (anti-HER2), and GW9662 (PPARγ inhibitor) for 72h, and the above experiments were repeated. Cell death was analyzed by flow cytometry and confocal microscopy. Results: In HB4aC5.2 cells, the oncogenic transformation by HER2 overexpression was associated with a lipogenic phenotype, which contributed to increase of lipid rafts formation, activation of survival and proliferation signals, as compared to HB4a normal cells (p<0.001). It is believed that PPARγ is the main regulator of cell lipogenesis. However, our data have shown that mTOR/SREBP pathway, exclusively mTORC1, was decreased concomitantly to increase of DEPTOR gene expression and AKT activation, in HB4aC5.2 cells. Also, the treatment with GW9662 did not change the expression of lipogenic genes, suggesting that lipogenesis seems independent of PPARγ activation, and that HER-2 overexpressing cells may use alternative mechanisms to maintain the lipogenic phenotype. DEPTOR is overexpressed in white adipose tissue and is associated with regulation of lipogenesis. Moreover, DEPTOR overexpression suppresses S6K1 but, by relieving feedback inhibition from mTORC1 to PI3K signaling, activates Akt. In HB4aC5.2 cells, only the DHA treatment decreased the lipogenic phenotype, DEPTOR expression, disrupted lipid raft, inhibited HER-2 signaling, and induced apoptosis (p<0.001). In addition the combined treatment using DHA and Trastuzumab increased cell death. Conclusion: We show that lipogenic phenotype was associated with HER-2 in breast cancer, can be induced early in the oncogenic transformation, and it seems important to promote survival and proliferation. Otherwise, its modulation by DHA increased death in tumor cells, suggesting this kind of FA may represent a useful tool for controlling the HER2-positive breast cancer.
Body: Background: Patients (pts) frequently report ‘fatigue’ as a consequence of breast cancer therapy but the true impact of cancer treatments on body composition and energy expenditure has not been measured.

Patients and Methods: Pts with stage 0-III were evaluated prior to any therapeutic intervention to assess baseline health status, at 6 months to assess acute impact of therapy, and at 12 months to assess chronic effects and ‘spontaneous’ recovery. Measurements included body composition, maximum watts produced and power envelope (watts/kg) based on laboratory testing, energy expenditure over 7 days in real world conditions, insulin resistance (HOMA), fatigue (BFI), quality of life scales (FACT-B), and serum for insulin-like growth factor-1 (IGF-1), adiponectin, leptin, markers of bone formation (P1NP, BSAP, osteocalcin), bone resorption (sCTX), and bone mineral metabolism (PTH, 25-OH Vit D).

Results: 45 patients have been enrolled; 25 have completed the 6 month assessment to date. Median age was 52 (30-68). Patients were analyzed separately based on therapies received.

*HOMA-IR was not assessed in patients known to have diabetes. ^Time to zero power quantifies the time over which patients can sustain generating motive power as a measure of endurance.

Week long bi-axial pedometry studies at baseline and six months revealed a decrease in pt activity between 17 and 23 percent, confirming the decrease in motive power seen in the power envelope and body composition tests. Enrollment continues to a planned total of 75 pts. Additional follow-up with 12 month assessment, as well as QOL and serum data will be presented.

Conclusions: Pts in this study were more deconditioned than expected based on population normative data. Systemic therapy had a profound impact on body composition with a substantial decrease in lean muscle mass with a corresponding increase in % body fat and decrease in the ability to generate and sustain motive power. Our data suggest that most patients would not be able to participate in or comply with commonly proposed exercise interventions and physical activity recommendations. Future interventions need to be restructured, following the model of individualized rehabilitation with careful assessment of the pts baseline status to improve the health of breast cancer survivors.
Title: BMI and metabolic factors in long-term breast cancer survivors: Changes from diagnosis and comparison to non-breast cancer controls

Ana Elisa Lohmann¹,², Marguerite Ennis³ and Pamela J Goodwin¹,². ¹Samuel Lunenfeld Research Institute, Sinai Hospital, Toronto, ON, Canada; ²Division of Medical Oncology and Hematology, University of Toronto, Toronto, ON, Canada and ³Applied Statistician, Toronto, ON, Canada.

Body: Background: The metabolic syndrome is associated with poor breast cancer (BC) outcome. We evaluated changes from diagnosis in metabolic factors and BMI in long-term survivors and compared their status at long-term follow-up (LTFU) to that of age-matched women with no history of BC.

Methods: A total of 535 women with early breast cancer were enrolled between 1989 and 1996 and followed prospectively. From 2005 to 2007, those alive without distant recurrence were re-contacted to participate in a long-term followed-up study and 285 agreed. A control group of 167 age-matched women without cancer history was recruited from women presenting for screening mammograms. Mean changes in metabolic factors from diagnosis to long-term follow-up were assessed with paired t-tests. In spite of matching, controls were younger and had higher income than survivors and the comparison to controls was made using age-adjusted regression models. Variables were transformed to normality before statistical testing.

Results: With a median follow-up of 12.5 years, BC survivors gained on average 2.35 kg and BMI, waist and hip circumference, waist-hip ratio, glucose, insulin, HOMA, total cholesterol and its components (but not triglycerides) increased significantly. After age adjustment, waist circumference, glucose, HOMA and total triglycerides were significantly higher in BC survivors compared to controls

Despite exclusion of BC patients with diabetes at study entry, 24.9% of BC survivors self reported diabetes or pre-diabetes (1.99%/year) versus 12.6% in controls (OR 2.3, p= .0017).

Conclusion: The metabolic status of long-term BC survivors deteriorated over time and age-adjusted at LTFU were worse with respect to a number of factors compared to the control group.
Title: Prevention of aromatase Inhibitor (AI)-induced joint symptoms with omega-3 fatty acid supplementation: A randomized placebo-controlled pilot study

Maryam B Lustberg1, Tonya Orchard6, Xueliang Pan6, Raquel Reinbolt1, Amanda Logan1, Joanne Lester2, Rachel M Layman1, Erin Macrae1, Ewa Mrozek1, Bhuvaneswari Ramaswamy1, Robert Wesolowski1, Michael Berger1, Michael Knopp2, Charles Loprinzi6, Charles L Shapiro1 and Lisa Yee1. 1Ohio State University Comprehensive Cancer Center & The Stefanie Spielman Comprehensive Breast Center, Columbus, OH; 2Ohio State University Comprehensive Cancer Center, Columbus, OH; 3Ohio State University, Columbus, OH and 4Mayo Clinic, Rochester, MN.

Body: Introduction: AI-induced joint symptoms negatively impact drug adherence and quality of life. Based on observations that n-3 polyunsaturated fatty acids (PUFAs) have anti-inflammatory effects and that the mechanism of AI-induced joint symptoms may be partly due to inflammation, we hypothesized that women taking more n-3 PUFAs are less likely to develop AI-induced joint symptoms.

Methods: We conducted a randomized, double-blind, placebo-controlled study comparing n-3 PUFA vs placebo in postmenopausal breast cancer patients starting adjuvant Al. Participants were randomized to n-3 supplements [2.58 g eicosapentaenoic acid + 1.74 g docosahexaenoic acid/day; Marine Nutriceuticals, Mt. Bethel, PA] vs matched placebo for 24 weeks (wks). Primary endpoints was feasibility; secondary outcomes were self-reported symptoms as assessed by the Brief Pain Inventory short form (BPI-SF), Functional Assessment of Cancer Treatment, Breast & Endocrine Symptoms (FACTB-ES), and Stanford's Health Assessment and Disability Index (HAQ) at baseline prior to AI receipt, 12 and 24 wks. Compliance and toxicity were evaluated monthly. Serial peripheral blood n-3 PUFA levels and inflammatory cytokines (IL-6, TNFR2, IL-17) were drawn. MRI of hands/wrists was performed in selected patients using a 3 Tesla dedicated wrist coil at baseline and treatment end.

Results: Forty-four women were enrolled and randomized to study drug; 42 received ≥1 cycle (4 wks) of treatment; 36 had ≥1 post treatment evaluation at wk 12 or 24. Median age was 59.5 (range 43-76); history of prior taxane (n=15, 34%). The two groups' baseline characteristics were similar. Overall, 93% and 88% of patients took >80% of the placebo and n-3 PUFA doses, respectively. Baseline erythrocyte n-3 PUFA was similar for both groups (6.6% ± 1.6%, 7.2% ±1.9%, p=0.20), but higher in the n-3 PUFA arm by wk 24 (6.5%±1.0% vs 15.0%±3.3%, p<0.001). Most toxicities were grade 1; the n-3 PUFA arm had only 1 (2.5%) grade 3 toxicity (diarrhea). The n-3 PUFA arm reported lower mean BPI-SF scores after treatment [(-.0.28/-.25 at week 12/24); but not statistically significant compared to placebo (p=0.494 and 0.601)]. Based on BPI-SF, the n-3 PUFA arm reported less interference of pain symptoms compared to placebo at 12 weeks (-.72, p=0.08). This arm also had a decreased walking, activity and working (WAW) score on BPI-SF at 12 weeks (-.81 p=0.05), and reported significantly greater pain relief from medications at 12 (p=0.043) and 24 weeks (p=0.011). Both arms had similar baseline and wk 24 serum IL-6 levels; levels decreased from baseline to wk 24 in the n-3 PUFA arm (-0.54±0.25, p=0.048). There was a non-significant trend (p= 0.2) toward decreased wrist inflammation by MRI imaging at 24 wks in the n-3 PUFA arm.

Conclusions: This is the first randomized pilot study to show that n-3 PUFA supplementation to prevent AI-induced joint symptoms is feasible and well tolerated. There is preliminary evidence that this intervention may help reduce the burden of AI-induced arthralgias.

OSU Study #11022; ClinicalTrials.gov Identifier: NCT01478477. Grants from the National Cancer Institute (CA037447-26) to the Alliance for Clinical Trials in Oncology supported this pilot study.
Introduction
Chemotherapy-induced peripheral neuropathy (CIPN) is a dose-limiting toxicity of several chemotherapy drug classes, including taxanes. Peripheral neuropathies have been shown to lead to pain, falls, and difficulty in walking and performing activities of daily living in a variety of patient populations. Although the prevalence of CIPN has been noted in cancer patients, the development of self-reported symptoms, gait changes and balance changes during treatment have not been well explored to date. We hypothesized that the use of taxane-based chemotherapy will result in significant changes in spatiotemporal gait and balance parameters, as well as self-reported quality of life and function.

Methods
We characterized the alterations in gait and balance that occur in non-metastatic breast cancer patients during taxane chemotherapy. We evaluated (1) spatiotemporal gait parameters, including cadence and step length, and (2) balance parameters, including time-to-contact and 95% ellipse area, using each patient as her own control. Laboratory assessment of gait and balance was conducted at baseline and at completion of therapy in selected patients. We compared the natural history of changes in gait and balance parameters with changes in CIPN status as measured by validated patient reported outcomes, including EORTC QLQ-C30, CIPN-20, and Brief Pain Inventory Short Form (BPI-SF), and the Duke Activity Status Index (DASI). Time points included pre-chemotherapy, after each cycle of chemotherapy, and one month after the end of therapy to collect information on neuropathy, pain and functional capacity. The preliminary data were illustrated using individual plots; trend lines (changing over time) were based on least square means at each time point, which were estimated using the linear mixed models for repeated measures.

Results
To date, 15 patients with localized breast cancer have been enrolled; patient recruitment is ongoing. The median age is 42 years (range 25-67). Ten patients (67%) received weekly paclitaxel, 1 patient (7%) received paclitaxel every 2 weeks, and 4 patients (27%) received docetaxel every 3 weeks. Preliminary results with these 15 patients, based on least square means at each timepoint, showed trends in several parameters. As treatments progressed, patients tended to develop more difficulty in quiet balance and in their ability to actively shift weight in the sagittal and frontal planes. From the CIPN-20, they also tended to develop increased difficulty with sensory and motor systems. From the QLQ-C30, their global health status also tended to worsen. For most of these parameters, the largest changes were observed between the 2nd and 3rd treatments, though some changes were not observed until the 4th treatment. From the BPI-SF, no trends in pain symptoms or pain interference were observed within this preliminary cohort.

Conclusions
Gait and balance testing is feasible in the clinical setting. Preliminary observations suggest that balance, function and quality of life may all be affected by taxane therapy, even without pain symptoms. The findings of this study will enable us to better characterize the neurotoxic effect of taxanes and to ultimately test the effectiveness of preventative measures and interventions. Title: A prospective longitudinal study of the impact of breast cancer treatment with adjuvant chemotherapy or tamoxifen alone on ovarian reserve

Shari B Goldfarb1,2, Giuliano Bedoschi3,4, Eli Grunblatt5, Sumanta Goswami5, Tessa Cigler2, Jessica Quistorff1, Fernanda Pacheco3, Robert Stobezki1, Mark Robson1, Fred Moy3, Clifford Hudis1,2, Sujata Patil1, Maura Dickler1,2 and Kutluk Oktay3,4.
1Memorial Sloan Kettering Cancer Center, New York, NY; 2Weill Cornell Medical Center, New York, NY; 3New York Medical College, Valhalla, NY; 4Innovation Institute for Fertility Preservation and In Vitro Fertilization, New York, NY and 5Yeshiva University, New York, NY.

Body: Background: Many women with breast cancer (BC) of reproductive age would prefer to preserve their fertility and ovarian function, if possible. However, available information is insufficient to predict the likelihood and extent of ovarian damage that will be suffered by an individual woman. In prior studies, menses was used as a surrogate for fertility, but it is a poor marker of future fertility. Preliminary work suggests that anti-mullerian hormone (AMH) may be a better surrogate for ovarian reserve. The goal of this study is to delineate the extent of ovarian damage from specific treatment regimens by using serum AMH. Here we report results from the largest longitudinal study with a pretreatment evaluation to measure the impact of both chemotherapy (chemo) and tamoxifen (tam) on ovarian reserve in BC patients. Methods: A multi-institutional longitudinal IRB-approved study was performed in 207 premenopausal women with stage 0-III BC. AMH levels were evaluated at baseline and 1 yr post completion of adjuvant chemo or 1 yr post initiation of tam. After the exclusions (failure to follow-up, sample inadequacy, presumed PCOS and consent withdrawal), 115 women ages 26-46 (median 38) were available for analysis at 1 yr post treatment (primary endpoint). AMH levels were measured in frozen sera with an in-house ultrasensitive ELISA assay and were log transformed due to non-normal distribution. Results were analyzed with Wilcoxon rank sum test and repeated measures ANOVA to adjust for age, tam use and stage. Results: In the 115 evaluable women, 98 pts had HR positive BC & 17 had triple negative BC. 77 pts received anthracycline-based (ddAC-T/EC-T) chemo, 26 non-anthracycline-based chemo (TC/CMF/TH) & 12 tam only. In the 103 women who received chemo, compared to baseline (median 0.21 ng/ml, 0.001-3.9 ng/ml), AMH levels declined significantly (median 0.11 ng/ml, 0.001-4.47 ng/ml; p<0.0001) at 1 yr post chemo. The type of chemo, stage and adjuvant tam use did not significantly impact the results. In the 12 women who received tam only, compared to baseline (median 0.505 ng/ml, 0.010-1.27 ng/ml), AMH levels declined significantly (median 0.155 ng/ml, 0.010-0.91 ng/ml; p=.0049) at 1 yr. Despite a significant decline in ovarian reserve by AMH, 69% (66/95) of pts who received chemo had return of menses by 1 yr post treatment. Conclusion: This longitudinal study shows that BC chemo is detrimental to ovarian reserve. Although a decline in AMH was also seen in pts treated with tam only, this is a small cohort and the results are hypothesis generating. The decline in AMH may be due to ovarian stimulation from tam, which can cause predominance of larger follicles that produce less AMH rather than actual reduction in ovarian reserve. This needs to be studied in a larger cohort. The fact that the majority of pts resumed their menses despite a significant decline in their ovarian reserve by AMH indicates that resumption of menses is not the best measure of ovarian normalcy/fertility. This new info can be used for counseling pts in childbearing ages so they can make better informed decisions on fertility preservation, if desired. Supported by NIH RO1 HD053112, Jodi Spiegel Fisher Cancer Foundation and Susan G. Komen Foundation.
**Title:** Patient centered support in the survivorship care transition: Outcomes from the patient-owned survivorship care plan intervention

Elizabeth A Kvale¹,², Wendy Demark-Wahnefried³, Karen Meneses², Sejong Bae², Chao-Hui S Huang⁵, Casey B Azuero⁵ and Christine S Ritchie⁴,³. ¹Birmingham VA Medical Center, Birmingham, Al; ²University of Alabama, Birmingham, Al; ³University of California, San Francisco, CA; ⁴San Francisco VA Medical Center, San Francisco, CA and ⁵University of Alabama, Tuscaloosa, Al.

**Body:** Background: Survivorship care plans will be mandated for use by 2015. Few studies have focused on the care transition process, and few show an impact on the patient experience or health outcomes. This study examines the effect of a patient-owned survivorship care plan (POSCP) intervention on patient outcomes and care coordination. Based on a conceptual model that incorporates IOM survivorship priorities and the chronic care model, the POSCP intervention is a single coaching encounter utilizing motivational interviewing to engage patients in the development of a POSCP that incorporates health goals and strategies related to surveillance, symptom management, and health behavior.

Methods: 79 recent breast cancer survivors Stage I-IIIB were randomized to receive POSCP intervention (n=40) or usual care (n=39). Patient outcomes were assessed using SF-36 Health Survey (SF-36), Social/Role Activities Limitations, Self-Efficacy for Managing Chronic Disease Scale, and Personal Health Questionnaire Depression Scale (PHQ-9) at baseline and 3 month follow up. Care coordination was assessed using confirmed primary care physician (PCP) visits and reported discussion of survivorship plan at follow up. Logistic and linear regressions were conducted to examine the effect of intervention on care coordination, patient experience, and health outcomes.

Results: In this sample age M= 58.35, SD = 10.62, 81% (N=64) non-hispanic white, 16.5% (N=13) African American. A greater proportion of participants in the intervention group reported a confirmed appointment (59.5% vs. 51.4%) and discussed survivorship issues (47.4% vs. 35.1%) with their PCPs compared to those in the usual care group, however these differences did not achieve statistical significance (p= .70 and .65). After controlling for education and perceived financial adequacy, participants in the intervention group demonstrated significantly higher self-reported health (F (3, 70) = 3.57, p< .05), lower social role limitation (F (3, 70) = 3.82, p < .05), as well as a trend toward greater self-efficacy (F (3, 69) = 2.51, p = .07) compared to those in the usual care group. Results of paired-samples t-tests revealed a significant decrease in depression scores from baseline to 3 months follow up in the intervention group, t (36)= 3.21, p < .01, η^2 =.23. No between group differences were identified in symptom burden or patient activation.

Conclusion: This pilot study of a POSCP process utilizing motivational interviewing techniques to enhance patient engagement has a positive impact on patient outcomes and demonstrates promise as a strategy to improve survivor patient experience, care coordination, and health outcomes.
Title: Risk factors for lymphedema are dependent on level of axillary surgery

Sharon L Kilbreath¹, Kathryn M Refshauge¹, Jane M Beith², Leigh C Ward³, Owen A Ung⁵, James R French⁴, Louise Koelmeyer⁴, Katrina Kastania¹ and Jasmine Yee¹. ¹University of Sydney, Sydney, NSW, Australia; ²Chris O'Brien Lifehouse, Camperdown, Sydney, NSW, Australia; ³University of Queensland, Brisbane, Queensland, Australia; ⁴Westmead Hospital, Westmead, NSW, Australia and ⁵Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia.

Body: Background: Differentiation of lymphoedema (LE) risk factors for those who have undergone a sentinel node biopsy (SNB) from those who have undergone axillary node dissection (AND) is not considered, even though the incidence rates for the two are vastly different. In addition, events women are typically cautioned against have not been well investigated.

Methods: A prospective study was conducted in which women were recruited and assessed prior to surgery, and then seen within 4 weeks following surgery, and at 6, 12 and 18 months following surgery. Women were categorised as having LE if their bioimpedance interlimb ratio exceeded previously established thresholds. Following post-surgery assessment, women were asked to complete weekly diaries regarding events that occurred in the previous week. Risk factors were broadly grouped into demographic, lifestyle, breast cancer treatment-related, arm swelling-related, and post-surgical activities (eg, airplane travel). Crude association between each potential predictor and presence of arm swelling was then identified using unadjusted logistic regression. Those variables with P<0.2 at this initial screen were considered for inclusion in a logistic regression model. The final multivariable model retained all variables with P<0.1 or odds ratio> 2.0, taking into account biological plausibility. The final multivariable models were developed without and with consideration of the presence of swelling in the first year.

Results: 450 women (SNB group: 241; AND group: 209) were recruited and attended the final assessment; a subgroup of 243 women, of whom 112 had AND completed >70% of the weekly diaries. The incidence of LE for the SNB group was 3.3% (n=8) and 18.2% (n=38) for the AND group. The unadjusted risk factors for LE at 18 months for SNB included high BMI and absolute body weight, living alone and presenting at diagnosis with three or more other medical conditions. The final model for the SNB group included a high BMI and not living with a partner, explaining 21.3% of the variance. Inclusion of post-operative swelling in the model explained 48.4% of the variance. The unadjusted risk factors for LE at 18 months for AND included being older, low education, Stage 3, high number of nodes removed and involved, and radiotherapy to the axilla, and receiving taxane chemotherapy. The final risk factors model for the AND group included clinical stage 3, being older, low education, and receiving taxane-based chemotherapy, explaining 20.4% of the variance. The addition of any swelling within the first 6 months following surgery explained 36.8% of the variance. Notably none of the factors related to air travel, arm trauma, medical procedures (eg, blood pressure, injections, blood drawn on the affected side), or exercise which women are typically cautioned against differentiated women who had and did not get LE at 18 months.

Conclusion: Advice to women undergoing SNB should differ to that provided to those undergoing AND, and for both, we should not be burdening them with range of behaviors to avoid. Importantly, for women at high risk, periodic assessment in the first year should occur to identify and manage any arm swelling.

Title: Determination of the first evidence-based diagnosis of secondary upper limb lymphedema

Sharon L Kilbreath¹, Elizabeth S Dylke¹, Geoff P Schembri³, Leigh C Ward², Dale L Bailey¹, Deborah Black¹, Elizabeth A Bailey⁴, Jane M Beith⁴ and Kathryn M Refshauge¹. ¹University of Sydney, Sydney, NSW, Australia; ²University of Queensland, Brisbane, Queensland, Australia; ³Royal North Shore Hospital, St Leonards, NSW, Australia and ⁴Chris O’Brien Lifehouse, Camperdown, NSW, Australia.

Body: Background: The incidence of secondary upper limb lymphedema after treatment for breast cancer is unclear due to the wide variety of measurement tools and diagnostic thresholds that are used in both the literature and clinical practice. Furthermore, this lack of clarity in what constitutes lymphedema or not has prevented the progression of the field of lymphedema. Many of the thresholds have been chosen for ease of use only and have no evidence base to support them. The aim of this study, therefore, was to determine which clinical diagnostic threshold for unilateral upper limb lymphedema has the best sensitivity and specificity when compared to diagnosis by lymphoscintigraphy.

Methods: Women with and without a history of secondary upper limb lymphedema were assessed using lymphoscintigraphy, bioimpedance spectroscopy (BIS) as well as volume and circumference measurements using the perometer. Dermal backflow score was determined as the diagnostic criteria for the lymphoscintigraphy and was assessed by an experienced nuclear medicine physician. Determination of the presence of lymphedema by lymphoscintigraphy was compared with diagnosis by both commonly-used and normatively-determined diagnostic thresholds for circumference, volume and bioimpedance.

* Dylke et al, 2012; Sum of arm circumferences (SOAC); Circumference measure (Circ)

Results: For those with widespread dermal backflow, any clinical diagnostic criteria could differentiate between those with and without lymphedema. In contrast, for those with mild to moderate dermal backflow, only the normatively-determined threshold, set at 2 standard deviations above the norm, for arm circumference and full arm bioimpedance (Cornish et al 2001) had adequate sensitivity and specificity. Both of these thresholds had clinically relevant positive (23 and 10 respectively) and negative (0.2 and 0.3) likelihood ratios.

Conclusion: Evidence-based diagnostic thresholds have been established for the diagnosis of secondary upper limb lymphedema. In determining if lymphoedema is present in those with mild lymphedema, normatively-determined circumference and bioimpedance thresholds that account for limb dominance should be used. Adoption of these evidence-based criteria will allow, for the first time, comparison between studies, clarifying the incidence and risk factors for lymphedema, allowing the field to make meaningful progress forward in determining who is at-risk for lymphedema and how to prevent it from developing.

Title: Impact of radiation on cardiovascular outcomes in breast cancer patients

Angel Qin¹, Paula Silverman², Janice Lyons³ and Cheryl L Thompson⁴. ¹University Hospitals Case Medical Center, Cleveland, OH; ²Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH; ³University Hospitals Case Medical Center, Cleveland, OH and ⁴University Hospitals Case Medical Center, Cleveland, OH.

Body: Background: Radiation therapy is a key component in the treatment of breast cancer. Recent studies have attempted to detail the potential impact that radiation may have on the development of cardiovascular complications in patients with breast cancer. The results of these studies, however, are conflicting regarding the magnitude and clinical significance of the cardiovascular effects with the use of modern radiation techniques. The aim of our study was to examine cardiovascular outcomes in breast cancer patients who received radiation therapy compared to those who did not.

Methods: After IRB approval, all breast cancer patients who received systemic chemotherapy at University Hospitals Case Medical Center between 1998 and 2006 and with known radiation data were included in this retrospective study. A complete patient medical history including risk factors, comorbidities, and tumor and treatment characteristics were obtained from the institutional tumor registry and were confirmed by the medical record. Billing data provided dates of diagnosis for heart failure (HF), coronary artery disease (CAD), and arrhythmia. The patients were divided into three groups: no radiation, right sided radiation, and left sided radiation. The groups were compared to one another and then further subdivided and analyzed based on timing of diagnosis of CAD and HF. Multivariate analyses using a Cox proportional hazards model were conducted for each outcome adjusting for age and comorbidities.

Results: 1277 patients were included in this study with average follow-up of 7.3 years (SD =3.5). CT based planning was used for the majority of the patients. Radiation start dates were not available for 186 patients; these were estimated at 5.5 months after the initiation of chemotherapy. There was no significant difference between groups in the incidences of the cardiovascular outcomes (p>0.05). Further analysis after accounting for timing of diagnosis of CAD and HF showed there was a significantly shorter time to onset of CAD in the left sided radiation group compared to the right sided radiation group; 4.5 years (SD=2.2) compared to 6.5 years (SD=3.6) respectively, p<0.001. However, multivariate analyses were not statistically significant (p=0.47). The onset to HF was shorter in the right sided radiation group compared to the left sided radiation group; 3.5 years (SD 3.1) compared to 4.3 years (SD=3.5) respectively, p<0.001, but again, multivariate analyses were not statistically significant (p=0.43).

Discussion: In our study, we did not find a difference in the incidence of adverse cardiovascular outcomes among patients who did and did not receive radiation, both before and after correcting for timing of diagnosis. We did find a difference in the time to development of these adverse cardiovascular outcomes between the two radiation groups, but no difference was found in either the incidence or time to development when controlled for age and co-morbid conditions. This study suggests that there is little impact of radiation on cardiovascular outcomes using modern techniques that limit radiation exposure. Prospective longitudinal studies focused specifically on cardiac endpoints may be needed to fully understand the cardiovascular impact of radiation.
Objective markers of fatigue in women undergoing adjuvant chemotherapy for breast cancer

Carolyn Behrendt, Sarah Waliany, Paul Frankel, Sunita Patel and Joanne Mortimer. City of Hope Comprehensive Cancer Center, Duarte, CA.

Background. In breast cancer patients, fatigue is a leading detriment to quality of life. Objective markers of fatigue are needed to advance research into its treatment and prevention. To that end, we evaluated physical and neurocognitive tests as potential markers of fatigue before and after chemotherapy.

Methods. Women about to begin adjuvant chemotherapy for breast cancer were studied prospectively. Before and after chemotherapy, subjects were assessed on self-reported fatigue (Brief Fatigue Inventory, BFI), depression (CES-D), Pittsburgh Sleep Quality Index, body mass index (BMI), and 18 objective measurements: grip strength in dominant and nondominant hands, 6-minute walk, daily total energy expenditure (TEE) per accelerometer averaged over 1 week, and examiner-administered neurocognitive tests: grooved peg board in dominant and nondominant hands; digit symbol coding and symbol search (Wechsler Adult Intelligence Scale, 4th edition); 2 trail-making, 4 color-word interference, and 4 verbal fluency tests (Delis-Kaplan Executive Functioning System, D-KEFS). Due to correlation between markers, each was evaluated individually as a continuous variable in generalized linear models of BFI. Models used generalized estimating equations with independent correlation matrix. Covariates (age, tumor stage, BMI) and potential interaction between marker and time of assessment (pre- or post-chemotherapy) were considered.

Results. Of subjects enrolled (n=28), 3 withdrew before wearing the device; these were similar to evaluable subjects except for lower scores on digit symbol (p<0.002) and color inhibition (p<0.02). Another subject (a vigorous athlete age 36) was excluded, because she alone did not experience the primary endpoint (fatigue) at either assessment. Thus, the final sample was n=24 (age 50.3±9.5 years). BFI before chemotherapy was median 1.17 (interquartile range 0.33-3.50) and increased +2.11(+2.64) after chemotherapy. Worse sleep quality (p=0.003), greater grip strength in dominant (p=0.001) and nondominant hand (p=0.003), and higher daily TEE (p=0.03) were each associated with BFI after chemotherapy but not before. In contrast, better performance on each of 4 neurocognitive tests (D-KEFS color patch p=0.04, color word p<0.001, switch correlation p<0.001, switch accuracy p<0.001) was inversely associated with BFI before chemotherapy but not afterwards. Other neurocognitive tests and 6-minute walk were not associated with BFI. Only depression score was associated with BFI before chemotherapy but not afterwards. In contrast, better performance on each of 4 neurocognitive tests (D-KEFS color patch p=0.04, color word p<0.001, switch correlation p<0.001, switch accuracy p<0.001) was inversely associated with BFI before chemotherapy but not afterwards. Other neurocognitive tests and 6-minute walk were not associated with BFI. Only depression score was associated with BFI before (p<0.0001) and after (p<0.0001) chemotherapy; moreover, a given level of depression was associated with greater BFI after chemotherapy than before (interaction with time, p<0.0001). None of the models fit BFI data better when covariates were taken into account or when markers were considered simultaneously.

Conclusions. Unlike neurocognitive tests, certain physical measures (grip strength in either hand, TEE, sleep quality) can serve as marker of the fatigue that follows cancer treatment. Grip strength has the advantage of being both objective and efficient to measure. No marker currently studied is suitable for comparing fatigue pre- versus post-chemotherapy, however.
Title: Effect of a 12-week supervised physical activity and healthy eating program on body weight, functional capacity and serum biomarkers in survivors of triple-negative breast cancer: A randomized, controlled trial

Linda Vona-Davis¹, Jame Abraham², Daniel Bonner¹, Diana Gilleland¹, Gerald Hobbs¹, Sobha Kurian¹, Mary Anne Yanosik¹ and Anne Swisher¹. ¹West Virginia University, Morgantown, WV and ²Cleveland Clinic, Cleveland, OH.

Body: Regular physical activity and healthy body composition are important predictors of good outcomes for breast cancer survivors, especially in overweight/obese individuals. However, individualized exercise and healthy eating programs have not focused on lifestyle changes and outcomes among women recovering from triple-negative breast cancer. Our purpose was to examine the associations between baseline levels of inflammatory cytokines and obesity-related adipokines after weight loss, diet and physical activity intervention in survivors of triple-negative breast cancer. We enrolled overweight/obese survivors (average time since diagnosis, 4 years) and randomly assigned them to a 12-week supervised exercise and low-fat diet (n=18) or a usual care group (n=10). The program consisted of supervised exercise 3 times/week, as well as 2 unsupervised sessions per week. The goal of our Get Fit for the Fight® program was to complete 150 min/week of moderate-intensity aerobic exercise. Participants completed a 3-day diet record during baseline testing and the dietitian recommended ways to cut calories from these typical eating patterns. The goal of caloric restriction was to decrease dietary fat in order for the participant to consume 200 kcal/week less. Assessments included aerobic fitness, body composition, and self-reported physical activity, mood and quality of life. Blood cytokines and obesity-related adipokines were also analyzed before and after the intervention period. The intervention group lost an average of 2% body fat compared with the control group (p<0.01). Significant (p<0.05) decreases were seen in the intervention group for body weight, BMI, and all skinfold measures except mid-axillary. Self-reported physical activity and breast-cancer specific quality of life also improved significantly in the intervention group from baseline to 12 weeks, indicating a shift from inactivity toward increasing time spent in moderate physical activity, primarily during weekends. No significant associations were observed between the intervention group and serum levels of inflammatory cytokines. However, BMI was significantly correlated (p<0.05) with serum leptin/adiponectin ratios, an indicator of insulin resistance. These findings indicate that a pragmatic lifestyle intervention with physical activity and healthy eating were consistent with improvements in body composition, functional capacity and quality of life for triple-negative breast cancer survivors. The intervention also evoked favorable changes in blood leptin/adiponectin ratios which are linked to reductions in central adiposity and improved insulin sensitivity.
Title: Risk of breast cancer related lymphedema after treatment with taxane-based chemotherapy: A prospective cohort study

Meyha N Swaroop¹, Cynthia L Miller¹, Nora Horick², Chantal M Ferguson¹, Melissa N Skolny¹, Jean O'Toole³, Lauren S Jammallo¹, Michelle C Specht⁴ and Alphonse G Taghian¹. ¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Massachusetts General Hospital, Boston, MA and ⁴Massachusetts General Hospital, Boston, MA.

Body: Background: Taxane-based chemotherapy is routinely used in the treatment of breast cancer and has been shown to improve both disease-free survival (DFS) and overall survival (OS). A common side effect of taxane-based chemotherapy is fluid retention in the extremities, which may increase the risk of breast cancer related lymphedema (BCRL). BCRL is a chronic swelling of the arms, breast, or trunk due to accumulation of lymphatic fluid in the interstitial tissues, which has a profoundly negative impact on quality of life. Little data exists regarding the impact of taxane-based chemotherapy and fluid retention on risk of developing BCRL. We sought to determine whether receipt of taxane-based chemotherapy for the treatment of breast cancer increases the risk of BCRL development in a large, prospective cohort of breast cancer patients.

Methods: We identified 569 patients diagnosed with unilateral breast cancer between 2005-2012 who underwent surgery and prospective screening for BCRL at our institution. All patients included in this analysis had ≥18 months of post-operative follow-up. Bilateral arm volume measurements were performed using a perometer preoperatively and every 3-7 months postoperatively. BCRL was defined as a relative volume change (RVC) of ≥10%. Clinicopathologic characteristics and treatment details were obtained by medical record review. Cox proportional hazard analyses were performed to analyze risk of BCRL. Arm measurements obtained after contralateral prophylactic surgery or diagnosis of metastasis were excluded to avoid potential confounding.

Results: Arm volume measurements from 569 patients were included with a median post-operative follow-up of 28 months (range 18-75.1). 33% (187/569) of patients received taxane-based chemotherapy in the neoadjuvant and/or adjuvant setting, and 92% (172/187) of these patients received pre-medication with dexamethasone to prevent hypersensitivity and reduce edema. 3% (18/569) received non-taxane based chemotherapy and 64% (364/569) received no chemotherapy. 23% (131/569) had axillary lymph node dissection (ALND), 61% (346/569) had sentinel lymph node biopsy (SLNB), and 16% (92/569) had no nodal surgery. At 24 months, the cumulative incidence of BCRL was 5.0% (95% CI: 3.15-7.81%) among patients who did not receive taxane-based chemotherapy, compared to 13.4% (95% CI: 9.17-19.4%) in the taxane-based chemotherapy group. On univariate analysis, taxane-based chemotherapy was associated with increased risk of BCRL (HR=2.2, p=0.0037), in addition to ALND, higher body mass index, greater number of lymph nodes (LNs) dissected and greater number of positive LNs (p<0.05 for all). However, taxane-based chemotherapy was not associated with increased BCRL risk on multivariate analysis (HR= 0.78, p=0.43), in which only ALND (HR=4.9, p<0.0001) and number of positive LNs (HR=1.1, p=0.02) remained significant.

Conclusion: Our results suggest that patients who receive taxane-based chemotherapy are not at an increased risk of BCRL compared with patients who received non-taxane or no chemotherapy. This data can be used to improve patient education and counsel those who experience temporary fluid retention while on taxane-based chemotherapy.
Title: Improved outcome of breast cancer survivors participating in a multidisciplinary cancer survivorship program at Texas Tech University Health Sciences in El Paso, TX

Zeina Nahleh¹, Rebecca Pasillas¹, Alok Dwivedi¹, Azadeh Nasrazadani¹, Rosalinda Heydarian¹, Luis Sanchez¹, Indika Mallawaarachchi¹, Cecilia Ochoa¹ and Edward Saltzstein¹. 'TTUHSC-Paul L.Foster School of Medicine, El Paso, TX.

Body: Introduction: Breast Cancer (BC) survivors in El Paso, TX include a majority of Hispanics. We have previously reported that these survivors have decreased mental and physical health related Quality of Life (QOL). We sought to determine whether BC survivors would benefit from participating in a comprehensive multidisciplinary BC Survivorship Program at the Garbar Breast Care Center (GBCC), as determined by improvement of performance on the following validated questionnaires: 1) Patient Health Questionnaire 9 (PHQ9), 2) General Anxiety Disorder 7 (GAD 7), and SF36 QOL questionnaires. Methods: After IRB approval, we recruited consecutive patients at our institution over 6 months starting October, 2013, and who are within the first 5 years post-diagnosis with Stages I-III BC and have completed surgery, chemotherapy and/or radiation therapy. Survivors were enrolled in the survivorship program staffed by an oncologist, a nurse practitioner, a nutritionist and a clinical psychologist. They participate in individual as well as group sessions. Survivors are initially screened for depression and generalized anxiety disorder using PHQ9 and GAD 7, in addition to assessing the patient’s QOL at baseline, and every 3 months. Survivors are provided with a personalized summary of all received treatment and follow up care plans; dietary counselling and individual meal plans, in addition to in-depth psychological assessment and an intervention using Mindfulness Based Stress Reduction. Results: 47 patients have been recruited so far and all but one completed baseline questionnaires; 17 and 7 respectively had 3 and 6 months follow up visits. 94% were Hispanics. Mean age 54 years. 38% of participants were younger than 50 years of age; Stage 1 BC (36%), Stage 2 (36%), and stage 3 (28%). 80% received chemotherapy; and 68% had hormone receptor positive BC and received endocrine therapy. The scores at baseline were: PCS representing the mean for the SF-36 QOL Physical Health was 46.0, and the MCS for Mental Health was 44.0, both below the population norm (50.0). Mean scores for GAD 7 was 7.54 and for PHQ 9 7.33, both abnormal (<5 on PHQ9 and GAD 7 are considered normal scores). At 3 months the scores were as follows: PCS 49.71, MCS 45.34, both improved (the higher the better); GAD7 5.18; and PHQ9 6.82 (both improved, the lower the better). At 6 months, same favorable trend continues: PCS 50.07 [SD 5.54, 44.29-53.35]; MCS 49.66 [SD 7.73, 38.93-62.41]; GAD7 5.00 (SD 3.70); and PHQ9 4.57 (SD 3.64).

Conclusion: BC survivors are benefiting from participating in the new BC Survivorship Program launched at Texas Tech in El Paso, TX. They have experienced improved mental and physical health related QOL, improved anxiety and depression by GAD7, and PHQ9, with scores reaching near normal values at 6 months into the program which continues to enroll BC survivors. This program represents a culturally appropriate model for Hispanic BC survivors. It is expected to continue to improve the quality of life of these patients, empower them in their transition from cancer treatment to survivorship and lead to improved psychosocial adjustment and normal social functioning with significant implication not only on survivors, but also on their families and the community.
Title: Randomized clinical trial assessing the impact of survivorship care plans on survivor knowledge

Amye J Tevaarwerk¹, Kevin A Buhr¹, Kari B Wisinski¹, Mark Burkard¹, Mindy Gribble², William Hocking², Wenjun Sun¹, SarahMaria Donohue¹, Jamie Zeal¹, Abigail Terhaar¹, Douglas A Wiegman¹ and Mary E Sesto¹. ¹University of Wisconsin, Madison, WI and ²Marshfield Clinics, Marshfield, WI, United Kingdom.

Body: Purpose: Efforts to inform survivors about long-term risks and planned follow-up after cancer treatment have increased. Survivorship Care Plans (SCPs) and care planning sessions have been recommended since 2005, yet the benefits of both SCP provision and care planning are only now being assessed. The impact of SCPs separate from care planning sessions is unclear, however SCPs alone require less time and cost to provide than SCPs combined with care planning sessions. We hypothesized that SCPs alone might enhance patient knowledge. In a randomized trial, we assessed change in patient knowledge of diagnosis, treatment, late/chronic side effects and followup care pre and post receipt of SCP.

Methods: Patients who completed primary treatment within the past 2 years for Stage 0-3 breast cancer were consented, enrolled, and randomized to immediate (intervention) versus delayed receipt (control) of an individualized SCP without care planning. All participants completed the Wisconsin Survey of Diagnosis and Management in Breast cancer (WiSDOM-B), a test of knowledge about one’s own breast cancer diagnosis, treatment and late effects scored out of 40 points. The survey was completed at both baseline and at four weeks (prior to delayed receipt); the primary outcome was change in score. The study was designed with 90% power to detect a between-group difference of 4 points (out of 40 possible).

Results: Between November 2013 and March 2014, we recruited 64 women aged 36-78 with Stage 0-3 breast cancer. Most participants were Stage 1-2 (n=50, 79%) with n=7 (10.9%) in Stage 3. Most had received chemotherapy (62.5%), endocrine therapy (89.1%), or radiation (76.6%).

At baseline, the average WiSDOM-B score was 28.3 out of 40 (70.8%), range 15.5-38.5. There was no evidence of change in score from baseline to four weeks for either the immediate SCP group (+0.41, 95% CI [-0.97, +1.79]) or delayed receipt control group (+0.95, 95% CI [-0.48, 2.38]). Observed variation was consistent with sample size assumptions, and the observed treatment difference (-0.55, 95% CI [-2.53, 1.44], p=n.s.) ruled out the prespecified clinically significant effect size of +4.0 (+10%). Overall, participants scored better on questions testing knowledge of diagnosis (side, year of diagnosis, lymph node test results, receptor status, and stage) and surgical side effects than on questions testing knowledge of other treatment (chemotherapy, radiation or endocrine therapy) side effects.

Participant satisfaction with knowledge and care team communication was collected pre and post SCP, as well as feedback on SCP content and use of the SCP. These analyses of selected questions shown to change post SCP by Nissen et al will also be presented.

Conclusion: In a controlled, randomized clinical trial, receipt of a SCP without care planning sessions did not appear to significantly increase survivor knowledge about cancer diagnosis, treatment and followup as assessed by the WiSDOM-B survey. Efforts to improve survivor knowledge should investigate the impact of care planning sessions or other interactive health information tools. A second study of patients (n=64) randomized to immediate or delayed receipt of SCPs, in conjunction with care planning sessions, is currently enrolling.
Title: Exercise and the influence of endocrine therapy on cardiac and metabolic outcomes in breast cancer survivors

M Tish Knobf¹, Lyndsey Harris², Karl Insogna¹, Barbara Smith³ and Sangchoon Jeon¹.¹Yale University, New Haven, CT; ²Case Western, Cleveland, OH and ³Michigan State University, Lansing, MI.

Body: Exercise and the Influence of Endocrine Therapy on Cardiac and Metabolic Outcomes in Breast Cancer Survivors

Background: Breast cancer survivors (BCS) are at higher risk for decreased cardiovascular fitness and illnesses due to excess weight and sedentary lifestyle. Exercise has been shown to improve fitness, body composition and helps to maintain weight but sparse data exists on the influence of endocrine therapy on these outcomes.

Methods: The Yale Fitness Intervention Trial (Yale FIT) was a 12 month RCT comparing aerobic-resistance exercise to home based physical activity. Female cancer survivors who were < 3 years of completing primary and/or adjuvant chemotherapy and within the first 5 years of menopause therapy were eligible. The aerobic-resistance intervention was conducted at a community fitness center 3 times/week and included 30 minutes of aerobic and 20-30 minutes of resistance exercise, supervised by an interventionist for first 6 months. The home based group received a flyer outlining recommendations for 30 minutes moderate intensity physical activity most days of week. Data were collected at baseline, 6 and 12 months.

Results: The majority of the 154 women enrolled were white, married, employed and average age was 52 years. At baseline, mean BMI was 29 (± 6.8), waist circumference 86.3 (± 15.3) and subjects reported expending a median of 773 MET minutes per week. A graded exercise stress test was used to measure cardiovascular function. The fitness center group increased time on treadmill (p=0.05) and had improved heart rate recovery (p=0.01) when compared to the home based group. No significant differences were found across time for metabolic outcomes by fitness center or home based group. However, when analyzed by type of endocrine therapy (30% were on an Aromatase Inhibitor (AI), 31% on Tamoxifen (TAM) and 39% were on no endocrine (E) therapy), there was a significant difference in serum insulin and insulin resistance between the fitness center and home based group for women taking TAM at 6 months (p=0.03) and 12 months (p=0.01). Specifically the insulin levels in the fitness center group remained stable while the home based group demonstrated increased serum insulin and insulin resistance. There was a trend for women in the home based groups who gained weight (> 5 lbs) to have higher insulin levels at 12 months (p=0.06). There were no significant changes at 6 or 12 months by group (fitness center or home based), by type of endocrine therapy or by weight change for total lipids, triglycerides, or HDL/LDL. To provide additional insight into the findings, analysis of cytokines and inflammatory markers is in progress.

Conclusions: This study confirms the cardiovascular fitness benefits of exercise but the relationship between exercise, endocrine therapy and weight on insulin levels is more complex. Exercise (aerobic-resistance and aerobic) combined with stable weight over 12 months resulted in relatively unchanged insulin levels. In contrast, only aerobic-resistance exercise (fitness center group) appeared to stabilize insulin levels in women who gained weight.

Title: Is there a genetic predisposition for cancer-related lymphedema?

Germaine D Agollah¹, Manuel L Gonzalez-Garay¹, John C Rasmussen¹, I-Chih Tan¹, Melissa B Aldrich¹, Chinmay Darne¹, Caroline E Fife², Renie Guilliod², Erik A Maus², Philip D King³ and Eva M Sevick-Muraca¹. ¹Center for Molecular Imaging, The Brown Foundation Institute of Molecular Medicine, University of Texas Health Science Center, Houston, TX; ²Memorial Hermann Hospital Center for Lymphedema Management, Houston, TX and ³University of Michigan Medical School, Ann Arbor, MI.

Body: Background: Breast cancer related lymphedema strikes approximately 20% of all breast cancer survivors and is associated with radiation and lymph node dissection. Yet it remains unknown why some women encounter lymphedema after minimally invasive sentinel lymph node biopsy while others who have extensive axillary lymph node dissections and radiation escape the incurable, chronic condition. It has been postulated by many that there exists a genetic predisposition for acquiring lymphedema after cancer treatment. While mutations HGF, cMET, GJC2 and VEGFR3 are thought to be potential predisposing genes for acquired lymphedema, until now, there has been no definitive causal evidence. Acquired lymphedema occurs after trauma, such as cancer treatment or surgical insult, while primary lymphedema is not associated with any known trauma, but attributed to inherited and somatic mutations.

Methods: In a larger study to discover gene variants associated with lymphatic dysfunction, we collected DNA and performed near-infrared fluorescence lymphatic imaging (NIRFLI) to identify abnormal lymphatic phenotypes in a nucleus family with two daughters who were diagnosed with rare primary lymphedema and a mother, who at the time of imaging, was diagnosed with acquired lymphedema with self-reported symptom after injury. Whole exome sequencing and cosegregation analyses was used to find previously known genes as well as new variants that could be predictive of lymphedema symptoms, despite the varied expressivity. Biological relevancy of variants was tested through cell culture studies following siRNA and drug inhibition in lymphatic endothelial cells (LECs), and overexpression of WT and mutant gene variants.

Results: A damaging mutation in HGF was passed to both daughters from the asymptomatic father who showed no abnormal NIRFLI phenotype. Yet the mother, who at time of study was found to have abnormal lymphatics through NIRFLI and diagnosed with both acquired and en tarda lymphedema attributed to minor trauma several years prior, had passed a mutation in SHIP2 to her daughters. Extended family members, including a breast cancer survivor, who agreed to the NIRFLI procedure and harbored the SHIP2 mutation, also possessed abnormal lymphatic phenotypes. Migration and tubulogenesis in LECs was arrested by SHIP2 knockdown, and when compared to WT overexpression, was attenuated following stimulation with mutant SHIP2. Furthermore, we found aberrant PI3K/AKT and MAPK/ERK signaling in LECs expressing mutant SHIP2 or transfected with SHIP2-siRNA.

Conclusions: Our studies identify SHIP2, a regulator of the PI3K/AKT pathway as a potential effector of lymphatic dysfunction. The identification of BCRL biomarkers could affect disease management in a growing cancer-survivorship population where an unmet clinical need with huge economical potential and quality-of-life impact exists. Validation of SHIP2 as a likely therapeutic target to prevent or treat lymphedema could ultimately influence cancer treatment in the following ways: (i) enable genetic screening of cancer patients to determine risk of developing lymphedema based on their PI3K/AKT status; and (ii) ameliorate the risk of lymphedema by seeking alternate cancer treatment options for those patients who harbor a genetic predisposition for lymphedema.
Perceptions and gaps of women living with advanced breast cancer: Results from the “Count Us, Know Us, Join Us” online survey in Latin America

Maira Caleffi

*Hospital Moinhos de Vento, Porto Alegre, Brazil.*

**Body:** Background: Patients with advanced breast cancer (ABC) represent a subgroup of BC patients who have a unique set of needs in their multiprofessional care, as the focus is more concerned with surviving the challenges of the disease, rather than being a survivor. However, little is known about these specific needs. A global Internet-based survey, "Count Us, Know Us, Join Us," was performed to identify and raise awareness of unmet needs of women living with ABC. Herein, the outcomes of respondents in Argentina, Brazil, and Mexico are presented.

Methods: The survey, conducted by Harris Poll between Oct 2012 – March 2013, sponsored by Novartis Oncology, comprised 40 questions to assess respondent demographics and baseline characteristics, diagnosis, metastatic spread of disease, overall health, family history, communication with the health care practitioner (HCP), information sources and resources, treatment, support, quality of life (QOL), satisfaction, emotional state, and economic impact. It was distributed online through locally based patient advocacy groups. Women ≥21 years old with BC that had spread to distant parts of the body beyond the breast and its local lymph nodes (stage IV) were eligible to participate.

Results: Overall, 1,273 participants from 12 countries completed the survey, including 302 respondents from Latin America (n=100, Argentina; n=100, Brazil; n=102 Mexico). Of these, 62% were between 40–59 years old and 59% had metastatic disease at diagnosis. The majority of patients in Brazil (64%) and Mexico (74%), but not Argentina (22%), were very satisfied with the communication they had with their HCP, although overall 74% wanted their HCP to also address their emotional needs. Just over a quarter (28%) felt isolated from the early stage BC community, and two-thirds (67%) felt no one understood what they were going through; 41% experienced a decrease in support from family and friends after being diagnosed. In total, 74% of women felt their QOL had been impaired moderately or strongly following diagnosis. Around half of respondents expressed dissatisfaction with aspects of their mental health, including outlook on life (43%), sense of control over their life (48%), emotional state (50%), and self-esteem (47%) following diagnosis. Moreover, moderate or strong negative impacts on jobs (67%) and finances (71%) were reported by applicable respondents. An impact on work was indicated by 89% of employed women and overall 66% stated that ABC interfered with their ability to work such that they suffered a loss of personal income, with the highest figure for respondents in Mexico (85%).

Conclusions: This survey has identified that ABC has a major impact on many aspects of a sufferer’s life. One of the key findings is the need for a larger psychosocial component in the care of women with ABC in Latin America. Engaging the commitment and collaboration of a multiprofessional care team, caregivers, patient organizations, and governments to improve the quality and breadth of care beyond therapeutic aspects may help to fulfill this unmet need and improve the general well-being of this often invisible patient population.
Title: Patient’s views of follow-up after treatment for breast cancer. A comparison of two approaches

Samantha T Muktar¹, Paul TR Thiruchelvam¹ and Dimitri Hadjiminas¹. ¹Imperial College Healthcare NHS Trust, London, United Kingdom.

Body: Background: Routine follow up of patients’ post treatment of breast cancer is standard practice in most countries. Follow up involves regularly scheduled clinical appointments with the aim of detecting early breast cancer recurrence and provision of psychological support to the patient. In the United Kingdom, financial constraint has led individual hospital trusts to revaluate the need for lengthy follow up schedules. Development of novel, less time intensive follow-up services, such as ‘open access follow up’ favour a more patient-led approach.

Aim: To assess patients’ views on breast cancer follow up, as well as the effect on patient satisfaction of transferring current clinical follow up to an ‘open access follow up’.

Method: We report the patients’ views on the basis of pooled data of a detailed survey performed in a large Breast Cancer Centre. All patients receiving regular clinical follow up care over a 6-month period were invited to participate in this prospective study. Patients were provided with a flow-chart, illustrating the current follow up, as well as a proposed ‘open access follow up’ process.

Results: Between November 2013 and April 2014, 304 patients were recruited into the study. 39% of patients were within the first year of their diagnosis with 18% more than 3 years into their follow up. Caucasian women made up the majority of our population group (81%), with 7% Indo-Asian, and 7% Afro-Caribbean.

The main expectation from follow up was surveillance for early detection of recurrence as expressed by 92% and anxiety of treatment side effects. 93% were satisfied with the current follow up they were receiving (satisfaction scores 7-10) and of those, 84% would choose to continue current follow up rather than move toward an ‘open access’ approach.

92% of patients favoured current clinical follow up over ‘open access follow up’, with 66% highlighting ‘open access follow up’ as an ineffective method of follow up. In stark contrast, 94% of patients reported current clinical led follow up to be effective. 91% of patients requested their follow up to be led by a breast surgeon and oncologist, rather than their primary care physician or community nurse. Interestingly, no significant correlation was established between age, ethnic background, distance from hospital and time from diagnosis with the type of follow up preferred.

Conclusion: Following treatment for breast cancer, patients prefer a more regular clinician-led service to a patient-led ‘open access follow up’ process. This may be explained by the observation that patients seek the reassurance of regular clinical review to identify recurrence early, however the psychological support of a clinical consultation cannot be underestimated. It may be inferred that patients who are satisfied in the follow up they were currently receiving are more likely to appreciate the current follow up system rather than moving to an ‘open access’ approach. Further study is warranted which investigates the impact of intensified surveillance on survival based on identification of recurrence and to repeat this study to seek consistency of opinion.

Title: Evaluating alcohol and tobacco use in an ethnically diverse sample of breast cancer patients: Implications for survivorship

Vivian J Bea¹,², Joan E Cunningham²,³, Dana R Burshell²,³ and Marvella E Ford²,³. ¹Medical University of South Carolina, Charleston, SC; ²Medical University of South Carolina Hollings Cancer Center, Charleston, SC and ³Medical University of South Carolina, Charleston, SC.

Body: Background/Objective: Data suggest that modifiable risk factors such as alcohol and tobacco use may increase the risk of breast cancer (BC) recurrence and reduce survival. According to 2012 data from the Centers for Disease Control (CDC) and Prevention Behavioral Risk Factor Surveillance System (BRFSS), 4.8% of women in South Carolina (SC) are heavy drinkers (>1 drink/day) with 9.6% having ≥4 drinks at least once in the past month (US state medians are 5.2% and 11.4%); 19.1% are current smokers (US state median 17.4%). Female BC mortality in SC is almost 50% higher in African Americans (AAs) than in European Americans (EAs; 27.5/100,000 and 19.1%, respectively). In SC, there is an AA subpopulation, the Sea Islanders, who carry the lowest AA rate of European genetic admixture. Given the substantial racial survival disparity we examined the patterns of alcohol and tobacco use in an on-going, ethnically diverse statewide study of women with recently diagnosed invasive breast cancer.

Methods: Participants were identified within 18 months post-diagnosis through the SC Central Cancer Registry (SCCCR). Women who opted into the study were interviewed via telephone, self-reporting data including race/ethnicity, educational status, alcohol consumption and tobacco use during the past 30 days. Published CDC guidelines were used to categorize alcohol and tobacco use.

Results: During the first 24 months of recruitment, 162 women have opted into our study; 132 have been interviewed and results analyzed (37 EAs and 95 AAs). Age at interview ranged from 38.9 to 90.2 years, with AAs slightly younger (p=0.071). Over half had more than a high school education with no difference by race (p=0.203).

Alcohol: The minority of participants self-identified consuming alcohol (28.8%). Heavy use was infrequent: two (1.5%) reported consuming on average >1 drink/day, and eight (6.1%) consumed ≥4 drinks on any one day. Consumption was less prevalent among AAs than EAs (p=0.063). Use tended to be lower among AAs (statistically not significant).

Tobacco: Smoking (daily or occasional) was reported by 12.1% of participants (AA vs EA: p=0.771).

Alcohol or Tobacco: Use of alcohol and/or tobacco was 1.6 times as prevalent among EAs compared to AAs (p=0.053).

Conclusions: Compared to self-reported state data few participants reported heavy alcohol consumption or current tobacco use, particularly AAs, but 35.6% of participants do use alcohol or tobacco. While these findings suggest that alcohol and tobacco may not contribute to the racial disparities in breast cancer mortality observed in SC, it is nonetheless imperative to reduce these modifiable risk factors and improve breast cancer outcomes for all breast cancer survivors, regardless of race and ethnicity.

Title: Metabolic syndrome is prevalent in women with newly diagnosed breast cancer

Louise C Wong¹, Carolyn Behrendt¹, Robin Smith¹ and Joanne E Mortimer¹. ¹City of Hope, Duarte, CA.

**Body:** Purpose: We estimate the prevalence of metabolic syndrome (MetSyn) among women with newly diagnosed breast cancer and explore potential risk factors.

**Methods:** From January 2012 to May 2014, women with newly diagnosed localized breast cancer were enrolled into a longitudinal survivorship study. At baseline, results of physical exam, use of concomitant medications, serum lipid profile and vitamin D were obtained from the medical record, while quality of life variables were measured via questionnaires in English. MetSyn was defined as at least 3 of 5 criteria: central obesity (BMI >30 or waist >=88 cm); triglycerides >=150 mg/dL; HDL cholesterol <50 mg/dL or cholesterol-lowering treatment; systolic >=130 or diastolic >=85 mm Hg blood pressure or treatment for hypertension; fasting glucose >=100mg/dL or diagnosis of Type 2 diabetes. Risk factors for MetSyn (age, education, serum vitamin D, self-reported energy in past month) were evaluated using multivariate logistic regression.

**Results:** Subjects (n=154) were age 52.0 ±10.1 years. Prevalence of MetSyn at baseline was 46.1(±4.0)%; for another 1.9(±1.1)% (n=3), MetSyn status was indeterminate due to lack of data on HDL and triglycerides. Among subjects with MetSyn (n=71), most had been diagnosed with hypertension (81.7%) and diabetes (61.4%). Without MetSyn (n=80), the latter conditions were much less prevalent (31.3% and 22.5%, respectively, both p<0.0001). Adjusted for race and year of accrual, the likelihood of MetSyn at baseline was higher per year of age (Odds Ratio (O.R.) 1.05, 95% CI 1.01-1.10, p=0.015), lower per increasing educational attainment (from less than high school to high school/some college, to bachelor’s, to graduate degree: O.R. 0.58, 0.36-0.93, p=0.024), and higher per increasing “time in past month with a lot of energy” (from little/no time to most of the time, to all of the time: O.R. 2.30, 1.11-4.75, p=0.025). An inverse association with serum Vit D (p=0.14) did not reach statistical significance.

**Conclusions:** Metabolic syndrome is present in nearly half of women newly diagnosed with breast cancer and is associated with age, less education, and more energy in past month.
Title: Improving quality of life among Latino breast cancer survivors: A national randomized control trial of patient navigators using LIVESTRONG’s Cancer Navigation Center

Amelie G Ramirez¹, Edgar Muñoz¹, Sandra San Miguel¹, Kip Gallion¹, Arely Perez¹, Leo Castillo², Sarah R Arvey³ and Frank Penedo². ¹University of Texas Health Science Center, San Antonio, TX; ²Northwestern University, Feinberg School of Medicine, Chicago, IL and ³LIVESTRONG, Austin, TX.

Body: Purpose: Latina breast cancer survivors experience an unequal burden of unmet needs after treatment, which compromise their health care and wellness, experts recommend providing psychological services as an integral part of quality cancer care. Methods: Redes En Accion: The National Latino Cancer Research Network and LIVESTRONG partnered to conduct a randomized control trial utilizing trained, bilingual, bicultural patient navigators to improve wellness and access to psychosocial services among non-metastatic Latino breast cancer survivors from Texas and Chicago. The trial tests the efficacy of patient navigation (PN) in improving general and disease-specific quality of life (QoL), treatment compliance, and identification of mechanisms that may promote quality of life. The study involves a 2 X 4 randomized repeated measures design with an experimental condition (combined PN over three months with access to the LIVESTRONG Cancer Navigation Center [LCNC] services [PN+LCNC]) versus a control condition (PN only) as the between-groups factor, and time-point (baseline/pre-randomization [T1]; post-PN [3-months post T1; T2], and 6 [T3] and 12 months [T4] follow up after T2) as the within groups factor. LCNC provides free, bilingual support to U.S. cancer survivors throughout the cancer journey. LCNC also refers to survivors to services addressing their medical, economic and psychosocial needs, and monitors client contact and access outcomes. Preliminary Results: A total of 128 Latina women with early stage breast cancer have been randomized into either our control (Standard Patient Navigation; PN) or our experimental (Enhanced Patient Navigation; EPN) conditions. Complete data for multiple regression analysis on 76 randomized Latina women who completed baseline and first follow up assessment is available. At baseline, we identified major stated needs by our participants. These included fear of recurrence, more information regarding their disease, and assistance in communicating with the medical team. The top three physical functioning concerns stated by our participants included lack of energy/fatigue, interference with daily routines and poor physical well-being. Consistent with prior work with Hispanic cancer survivors, our sample reported significantly lower (over 1.5 standard deviation below) general health related quality of life, physical well-being and emotional well-being as measured by the FACT-G. Exploratory analyses have begun to reveal that there are several significant moderators of the effects of the intervention across several outcomes. At conference, we will present quality of life data on breast cancer participants, exploratory analysis, and lessons learned. Discussion: Limited work has addressed the psychosocial needs of Latina breast cancer survivors. Culturally sensitive patient navigation (PN) could address these needs and significantly improve breast cancer survivorship.
Title: Symptoms, desire for help, and quality of life among recent breast cancer survivors

Steven C Palmer\textsuperscript{1}, SarahLena L Panzer\textsuperscript{1}, Karen Glanz\textsuperscript{1}, Marilyn M Schapira\textsuperscript{1}, Angela M DeMichele\textsuperscript{1} and Linda A Jacobs\textsuperscript{1}.
\textsuperscript{1}University of Pennsylvania, Philadelphia, PA.

Body: Introduction:
Advances in detection and treatment have led to improved survival among breast cancer (BC) patients and 89% can expect $\geq$5 year survival. Progress comes at a cost, however, and patients experience lasting effects from disease and treatment. It is not clear how these effects impact quality of life (QoL) achieved by BC survivors. We examined relationships between symptoms, desire for help, and QoL among recent BC survivors.

Method:
Eligibility included non-metastatic BC treated $\leq$ 1 year prior and attendance at a survivorship clinic. QoL was assessed with the SF-12. 19 common symptoms were assessed on a 0-5 bother scale. Participants reported desire for help item for each symptom rated $\geq$ 1.

Results:
171 primarily white (73%), middle aged (M=54.9 yrs), and Stage I (58%) BC survivors were recruited. Both Physical (M=48.1) and Mental (M=53.8) QoL were similar to national norms. Survivors reported an average of 12 symptoms, most commonly Fatigue (90%), Insomnia (75%), Hot Flashes (73%), and Joint Pain (70%). Most bothersome symptoms included Joint Pain (M=2.9), Decreased Sexual Drive (M=2.8), Hot Flashes (M=2.8), and Vaginal Dryness (M=2.7). Participants desired help with few symptoms (M=2.3), primarily Weight Gain (50%), Joint Pain (45%), and Numbness in Hands/Feet (44%). Both Physical and Mental QoL were negatively associated with number of symptoms experienced ($r = -.46$ and $-.41$, respectively) and number of symptoms for which help was desired ($r = -.16$ and $-.41$, respectively).

Conclusion:
Symptoms are common among recent breast cancer survivors and negatively impact Physical and Mental QoL. Desire for help is less common, though similarly associated with impairment in QoL. Assessing QoL in isolation from symptom burden may miss important areas for which remediation is possible and could result in improved QoL. Patient education regarding the potential for and value of symptom reduction may be needed in BC survivors.
Title: Oral health-related quality of life in women with early stage breast cancer

Linda S Taichman1, William G Giannobile1, Thomas M Braun1, Marita R Inglehart1 and Catherine H Van Poznak1. 1University of Michigan, Ann Arbor, MI.

Body: Introduction: Aromatase inhibitors (AI) are a well-established component of the adjuvant therapy in postmenopausal (PM) women with hormone receptor positive (HR+) early breast cancer (BCA). AIs are associated with side effects that may adversely affect the quality of life (QoL). The impact of AIs and on oral health-related QoL (OHRQoL) in women with BCA is unknown. To generate data on the impact of adjuvant AIs on OHRQoL we performed a prospective, longitudinal, cohort study assessing patient reported outcomes.

Methods: PM women with early BCA were eligible if they were on an adjuvant AI for 3 to 12 months. AI patients were recruited from the Breast Medical Oncology Clinic. The Control group consisted of PM women without BCA who were not on AI therapy and were recruited at the time of screening mammography. Study participants provided socio-demographic information and completed questionnaires OHRQoL which included the Michigan Oral Health-Related Quality of Life (MOHRQoL) Scale, and Oral Health Impact Profile (OHIP-14) which both measure discomfort, dysfunction and disability resulting from oral problems on a 5 point scale. Presence of saliva status as a measure of oral health was measured by the saliva flow rate. Data was collected at baseline and at 6, 12 and 18 months. The baseline data is presented here. The student t-test and chi-square test were used to analyze outcomes. The Pearson correlation coefficient was used to evaluate the correlation between the OHIP-14 and the amount of saliva.

Results: The study met its target accrual of 58 PM women; 29 with BCA on AI and 29 controls. Median time on AIs at study entry was 5.7 months. Demographics were similar regarding age, education, income level, frequency of dental visits, and dental insurance status across both groups. The OHIP-14 score varied by AI use (p=0.02) and duration of AI use (p=0.03) where the lowest poor OHRQoL was found in AI users less than 6 months. Patients receiving AI therapy had significantly lower perception of OHRQoL for the individual OHIP-14 items: "I have had pain in the mouth", "I have had to limit my diet", "I have had painful aching in my mouth", "I have had to limit foods I eat" and "I have felt tense because of problems with my mouth" compared to controls.

Conclusions: This study is the first to report on the OHRQoL among PM women with early BCA using AIs. The baseline data demonstrates a significantly lower OHRQoL in those on AIs compared to controls. Dimensions that were particularly relevant were physical pain, psychological discomfort and physical disability. Analysis of serial time points is ongoing.
Title: Determinants of weight gain after breast cancer diagnosis: Results from the prospective SU.VI.MAX cohort

Laurent Zelek¹,², Fabien Szabo¹, Serge Hercberg¹, Pilar Galan¹ and Mathilde Touvier¹. ¹Sorbonne Paris Cité, Nutritional Epidemiology Research Team (EREN), Epidemiology and Biostatistics Center, Inserm U1153, Inra U1125, Cnam, Universities Paris 13, Paris 5, and Paris 7, Bobigny, France and ²Avicenne Hospital, Bobigny, France.

Body: PURPOSE To identify correlations between lifestyle related risk factors and weight gain after breast cancer. MATERIAL AND METHODS The SU.VI.MAX randomized trial was initially designed to assess the effect of a daily antioxidant supplementation on the incidence of cardiovascular disease and cancer. A total of 13,017 subjects were enrolled in 1994–1995. Health events occurring during the follow-up (1994-2007) were self-reported by participants. Pathological reports were used to extract cancer characteristics. Anthropometric measurements were taken one year after inclusion in the study and repeated every two years during follow-up. Participants were invited to provide a 24-h dietary record every two months. Among the 258 invasive breast cancers, 169 had complete weight data before and after cancer diagnosis and were used for analysis. When measured weight and height were not available before diagnosis (n=28), self-reported weight and height were used instead of measured data. After cancer diagnosis, all anthropometric data were measured by study nurses. Women with weight gain (WG) ≥5% (moderate WG) were compared to those with WG <5% by multivariate logistic regression, according to the following factors: menopausal status, educational level, physical activity (irregular, <1h equivalent walking/day, ≥1h equivalent walking/day), smoking status, supplementation group of the trial, weight status before diagnosis, chemotherapy, endocrine therapy, tumor size, pN, mitoses and grade, ER and PR status, mean daily energy intake before diagnosis (<, ≥ median=1865 Kcal/d). The same analysis was performed to compare women with WG ≥10% (severe WG) to those with WG <10%. We also calculated the difference between weight before diagnosis and weight at the age of 20 (“lifetime weight change”) and we tested its association with the risk of moderate or severe WG. RESULTS Mean age at diagnosis was 54.4 y. Mean duration between pre- and post-diagnosis weight measurements was 5.8 years. Among the 169 women included, 59.8% were post-menopausal at diagnosis and 28.4% were already overweight before cancer diagnosis. 66 women had a WG ≥5% and 25 had a WG ≥10%. Women who practiced more physical activity at baseline were less inclined to face moderate WG (OR=0.42 (0.18-0.97), P=0.04). Moderate WG was also directly associated with hormone receptors status. All other studied factors (including treatment type or energy intake) were not associated with the risk of moderate WG. Surprisingly, tumor size was directly associated with the risk of severe WG (mean tumor size = 14.6mm among women with <10% WG versus 20.1mm among women with ≥10% WG, P=0.04). All other studied factors were not associated with the risk of severe WG. Lifetime weight variation was not associated with the risk of moderate or severe WG. CONCLUSION Physical activity seems to have a protective effect against moderate WG. Severe WG raises risk for recurrence (Caan B, et al. 2012), but since it is also linked with tumor size, we hypothesize that this relation is more complex than a direct causal effect of WG on recurrence risk.
Title: Surgery for breast cancer in the elderly is associated with better outcomes

Yasmin A Jauhari1, Pam Chaichanavichkij1 and Richard J Sainsbury1. 1Isle of Wight NHS Trust, Isle of Wight, United Kingdom.

Body: Background
Breast cancer often presents differently in the elderly with more neglected disease. There is patchy evidence to support surgery as a preferred management tool with a positive survival outcome. The objective of this study was to 1. Understand disease presentation and management of patients diagnosed with breast cancer over the age of 80, and 2. To review survival outcome between conservative and surgically managed elderly breast cancer patients.

Method
A retrospective single centre case series was conducted from 2008 to 2014 on patients aged 80 and over at breast cancer diagnosis. Survival outcome between conservative and surgical treatment groups were reported by Kaplan Meier analysis, with comparison by log-rank test.

Results
There were 156 patients, with a median age of 86.6 years (range 80 – 107). 67.9% had invasive ductal carcinoma. At presentation, 9.6% had T4 fungating lesions and 11.9% had distant metastatic disease. The median tumour size was 25mm (range 4 – 85mm) and 81.5% were oestrogen receptor positive.
Conservative treatment (44.9%, n = 70) was accounted for in 80% of cases by patient choice and/or pre-morbid status precluding surgery. 55.1% of patients underwent surgical resections, the majority of which were performed with curative intent (96.4%). 11 patients had surgery under local anaesthetic with no complications. Median duration of hospital stay was 1 day.
Conservative vs. surgical cohorts were comparable in co-morbidities aside from age (89.6 +/- 5.1 vs. 85.2 +/- 4.2 years, p = 0.005) and dementia (18 vs. 9 (p = 0.015). The overall survival for those treated conservatively was 29 +/- 4.1 months compared to 40 +/- 6.1 months (p = 0.004) for those having surgery.

Conclusion
The elderly are more likely to present with advanced or neglected breast cancer. Those undergoing surgery had a significant survival advantage and this modality should be offered unless co-morbidities are severe.
Title: High serum levels of 25-hydroxyvitamin D are associated with better quality-of-life, and lower levels of perceived stress, depression, and fatigue among breast cancer survivors

Chi-Chen Hong\textsuperscript{1}, Song Yao\textsuperscript{1}, Yali Zhang\textsuperscript{1}, Shicha Kumar\textsuperscript{1} and Christine Ambrosone\textsuperscript{1}. \textsuperscript{1}Roswell Park Cancer Institute, Buffalo, NY.

Body: Background: Recent evidence suggests a role for vitamin D in breast cancer etiology and survival. Although data are not definitive, breast cancer survivors might derive additional benefits from adequate vitamin D levels, including better quality-of-life (QoL) and psychosocial well-being.

Objective: Using a prospective study design, we examined associations between QoL and psychosocial functioning among breast cancer survivors and circulating 25(OH)D levels at the time of initial breast cancer diagnosis and 1 year post diagnosis.

Methods: Women (n=504) with incident breast cancer (stages 0-III) were recruited prior to initiating breast cancer treatment at Roswell Park Cancer Institute (RPCI), with 372 patients also providing data 1 year later. Demographic and clinical data were obtained from the RPCI Surgical Oncology Breast Database. At each time point, participants provided blood samples and completed surveys on mental and physical health (SF36 Health Survey), perceived stress (Perceived Stress Scale), depression (Center for Epidemiologic Studies Depression Scale), and their experiences with fatigue (Multidimensional Assessment of Fatigue Scale). Serum 25(OH)D levels were measured by immunochemiluminometric assays.

Results: Median 25(OH)D levels at diagnosis and 1 year post were 23.8 ng/ml (range 0.1-67.4) and 26.6 ng/ml (range 3.0 – 80.0), respectively. At the time of diagnosis, multivariate logistic regression analyses indicated that women with sufficient levels of 25(OH)D (≥ 30 ng/ml) had ~50% lower odds of reporting poor physical health (OR=0.52, 95% CI: 0.29, 0.90) or poor mental functioning (OR=0.54, 95% CI: 0.31, 0.95) compared to women with deficient levels (<20 ng/ml). Women with higher 25(OH)D were also less likely to report high levels (>median) of perceived stress (OR=0.45, 95% CI: 0.26-0.80), depression (OR=0.46, 95% CI: 0.25-0.83) or fatigue (OR=0.54, 95% CI: 0.31, 0.92). Findings were similar 1 year later, with reduced odds of poor physical health (OR=0.47, 95% CI: 0.24-0.93), poor mental health (OR=0.62, 95% CI: 0.33, 1.13), high levels of perceived stress (OR=0.67, 95% CI: 0.36, 1.25), depression (OR=0.33, 95% CI: 0.15, 0.71), and fatigue (OR=0.45, 95% CI: 0.24, 0.84). Changes in vitamin D levels over the 1 year period were also assessed. While none of the relationships were significant, women in the upper tertile of vitamin D change (>3.99 ng/ml) were more likely to report low mental health and higher levels of perceived stress at 1 year compared to patients with declines in 25(OH)D of >0.95 ng/ml, but were less likely to report poor physical health or fatigue. This may have been due, in part, to women being somewhat more likely to use vitamin D supplements if they reported lower mental health QoL scores. Changes in circulating 25(OH)D levels during this 1 year period were strongly associated with use of supplements (p=0.001).

Conclusions: Breast cancer survivors with adequate vitamin D levels were less likely to report poor QoL compared to women with deficient vitamin D levels. Maintenance of optimal vitamin D levels may help improve breast cancer patients’ QoL as they go through breast cancer treatment.
Title: What is a healthful diet? – Cancer survivors' interpretations of their own dietary recall data

Ann C Klassen\textsuperscript{1,2}, Katherine C Smith\textsuperscript{2}, Michelle Brosbe\textsuperscript{1}, Kisha Coa\textsuperscript{2}, Susan Hannum\textsuperscript{2} and Laura Caulfield\textsuperscript{2}. \textsuperscript{1}Drexel University School of Public Health, Philadelphia, PA and \textsuperscript{2}Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.

Body: Background
The number of long-term cancer survivors will continue to grow, and developing strategies for tertiary prevention of recurrence, cancer-related comorbidities, and general chronic disease-related health burden is critical. Nutrition and energy balance are increasingly recognized to play important roles in both decreasing recurrence risk, and improving health and well-being throughout survivorship. To inform strategies for nutrition education and behavior change for cancer survivors, we used a mixed methods approach to explore concepts about healthful diet and eating patterns among long-term cancer survivors.

Methods
We collected three ASA-24 dietary recalls from 53 breast, prostate and non-Hodgkins lymphoma survivors. Utilizing qualitative interviews, we provided participants with feedback on how their eating patterns compared to dietary guidelines, and asked respondents to reflect upon their diet and dietary changes.

Results
Like most American adults, respondents were not eating in accordance with many dietary recommendations. In terms of adequate intake of recommended nutrients, 68% met fruit and vegetable guidelines, but only 15% reported adequate intake of fiber. In terms of following recommendations for limits on intake, 89% reported diets that met guidelines for limiting alcohol intake, but only 55% met limits for cholesterol, 40% for saturated fat, 19% for caloric intake, and only 2% limited their sodium intake to within recommended levels. Respondents were often surprised by their own dietary patterns, and had differing conceptualizations of a "healthful" diet.

Conclusions
Cancer survivorship may provide motivation for dietary change, but survivors need nutrition education to identify specific strategies for dietary improvement.
Body: Background
Breast cancer (BC) is the most common cancer diagnosed in women. With advances in diagnostics and therapy, early stage disease has an estimated 85% 10-year overall survival. Cancer survivors have unique needs including screening for recurrence, psychosocial concerns, as well as routine health maintenance. There is growing evidence to support the safe transition from oncologist to primary care. This is challenging in the era of complex adjuvant and extended adjuvant programs, which are standard of care for women with hormone receptor positive BC.
In February 2013 the Wellness Beyond Cancer Program (WBCP), developed at the Ottawa Regional Cancer Program, started accepting BC patients. A risk stratification system enables the treating oncologist to determine the most appropriate care provider stream based on patient complexity and/or risk of relapse. There are three possible streams: primary care provider (PCP), nurse practitioner (NP), or oncologist. The program offers education on general and breast specific cancer survivorship issues. Unique to our program is a hormone re-assessment review (HRR), scheduled in advance, to discuss switching hormonal therapies and/or extended adjuvant strategies. A rapid re-entry system is in place for those with evidence of disease recurrence or a new primary.

Specific aims
The aims of our study are:
1. To describe unique aspects of WBCP developed for early stage BC patients
2. To assess efficacy of the WBCP
3. To evaluate safety of the HRR
4. To examine patient and primary care giver satisfaction with the program

Methods
All BC patients eligible for discharge through the WBCP will be included in the evaluation. We will evaluate patients by examining needs assessments completed at time of referral and one year later, as well as completed patient and PCP satisfaction surveys. The proportion of patients with changing scores, increasing or decreasing, will reflect improvements or worsening of needs. The proportion of both patients and PCP that are/are not satisfied with the program will be recorded and examined further.
For the HRR we will code the proportion of patients where the consult was requested and was "scheduled vs. not scheduled". Finally, the number/proportion of patients and reasons for re-entry will be captured.

Results
February 2013–June 2014, 1339 BC patients were referred to the program, 584 patients to PCP, 740 to NP, and 15 remaining with their oncologist. Early results are reported here with results of the surveys expected by December 2014. 7 patients have required re-entry for disease recurrence and 30 HRR have been booked. No cancer specific negative outcomes have been reported. Survey results addressing patient needs, empowerment and concerns are being collated, with PCP satisfaction results to be reported.

Conclusion
Our institution has endorsed evidence-based recommendations for an organized survivorship program and has taken it a step further by developing a strategy to address the unique long term needs of hormone positive early stage breast cancer. Early feedback supports that this program has increased patient and caregiver knowledge of survivorship issues and anticipates improved patient empowerment, without compromising cancer specific outcomes.
Title: Relationship of dietary and red blood cell polyunsaturated fatty acids to inflammatory markers in breast cancer survivors taking aromatase inhibitors

Tonya S Orchard¹, Xueliang Pan¹, Joanne Lester¹, Amanda Logan¹, Charles L Shapiro¹, Rebecca D Jackson¹, Martha A Belury¹, Lisa Yee¹ and Maryam B Lustberg¹. ¹Ohio State University, Columbus, OH.

Body: Introduction: A large body of literature supports modulation of inflammation by polyunsaturated fatty acids (PUFA). Inflammation may play a role in the painful joint symptoms commonly experienced by breast cancer survivors taking aromatase inhibitors (AI). AI-induced joint symptoms negatively impact drug adherence and quality of life in many breast cancer survivors. N-3 PUFAs, especially eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) have anti-inflammatory effects; in contrast, excess very long chain n-6 PUFAs may promote peripheral and joint inflammation. We hypothesized that breast cancer survivors with greater EPA+DHA or n-3/n-6 PUFA in their diet would have decreased inflammation and be less likely to develop AI-induced joint symptoms.

Materials and methods: This is a secondary analysis of PUFA intake self-reported from food frequency questionnaires and red blood cell (RBC) PUFA data from a randomized placebo-controlled pilot study comparing n-3 PUFA supplementation vs placebo in 44 postmenopausal women with breast cancer initiating first line adjuvant AIs. Primary outcomes were feasibility and tolerability; secondary outcomes were differences in clinical symptoms and inflammatory markers. Participants were randomized to 4.8 g/day DHA+EPA vs matched placebo for 24 weeks (wks). Serial peripheral blood samples were drawn for RBC PUFA levels and inflammatory cytokines (IL-6, TNFα-R2 and IL-17). Clinical symptoms were assessed by the Brief Pain Inventory short form (BPI-SF), FACTB-ES, and Stanford Health Assessment -Disability Index (HAS) at 12 and 24 wks. Compliance and toxicity were evaluated monthly.

Results: Median age of all 44 women enrolled and randomized was 60 years (range 43-76); breast cancer stage I (n=29), II (n=10), III (n=5); prior taxane (n=15, 34%). Baseline mean dietary intakes of n-3 PUFAs were: total n-3 PUFAs = 1.43 ± 0.86 g/d; EPA = 0.05 ± 0.05g/d; and DHA = 0.10 ± 0.11 g/d. There was a trend toward lower TNFα-R2 with higher dietary intake of EPA (p=0.09) and DHA (p=0.10). Baseline mean RBC EPA+DHA (n-3 Index) was 4.36% and the RBC n-3/n-6 ratio was 0.20. RBC total n-3 PUFAs were similar at baseline between n-3 treatment and placebo groups (6.6 ± 1.6%, 7.2 ±1.9%, p=0.20). RBC PUFAs were not predictive of baseline IL-6 or IL-17. However, the baseline RBC n-3 Index trended toward an inverse relationship with TNFα-R2 (r = -0.23, p 0.14)

Mean dietary intake of n-3 PUFAs did not change over 24 wks for the 30 women with complete FFQ data and blood samples: total n-3 = 1.38 ± 0.70 g/d; EPA = 0.06 ± 0.07 g/d; and DHA = 0.13 ± 0.14 g/d. Dietary EPA and DHA were significantly associated with lower TNFα-R2 (r = -0.40, p=0.02 for both) at 24 wks. RBC total n-3 PUFAs were significantly higher in the n-3 treatment vs placebo group at wk 24 (6.5%±1.0% vs 15.0%±3.3%, p<0.001). RBC EPA+DHA and RBC n-3/n-6 ratio were not predictive of inflammatory cytokines at 24 wks.

Conclusions: There was a trend toward lower TNFα-R2 in breast cancer survivors with higher dietary and RBC EPA and DHA before starting AIs, but only dietary intake of EPA and DHA was significantly related to lower TNFα-R2 after 24 wks of AI therapy.
INTRODUCTION: Although survivorship research focuses on quality of life after breast cancer treatments, it is usually initiated by providers and focused on previously reported side effects and consequences of treatment. Patients are often reluctant to report side effects they may experience during and after cancer treatment and providers are often reticent to ask. In an effort to explore the patient perspective, the Dr. Susan Love Research Foundation convened a collaboration of advocacy groups to "crowdsource" women’s questions regarding collateral damage from treatment. These concerns will then be incorporated into the Health of Women [HOW] Study, an ongoing, online cohort study of breast cancer open to anyone aged 18 or older.

METHODS: Emails to current HOW participants were sent out July 2013 to solicit questions about collateral damage. In October 2013, we undertook the design of a new website landing page for the submission of questions, partnered with other breast cancer advocacy organizations, and began collecting responses. Responses were then categorized to guide questionnaire development.

RESULTS: Sixteen breast cancer and other advocacy organizations came together to support this project. Emails to current HOW participants resulted in 1191 responses. The website landing page resulted in an additional 3000 responses. Overall, 16.8% of respondents complained of fatigue, 16.3% of memory problems, 15.7% of anxiety and/or depression, and 14.0% of numbness/neuropathy. Other less frequently reported problems included problems with nail growth, vision, hearing, urinary tract infections, and allergy-like symptoms.

CONCLUSION: Through this approach, we received an overwhelming number of responses about collateral damage from treatment. Many of the issues are known side effects, while others are less commonly reported, but debilitating nonetheless. We will next compare responses to previously validated questionnaires, develop a comprehensive collateral damage questionnaire for inclusion in the HOW Study, and generate a report for publication to be distributed to the participants.
A novel candidate for chemotherapy induced alopecia (CIA) through local modulation of apoptosis and inflammation

JiaWei Liu1,2, Saad Harti1, Shiiba Tadafumi1, Reiko Kondo1, Angelo Mello1 and Geert Cauwenbergh1. 1Legacy Healthcare, Lausanne, Switzerland and 2Harvard Medical School, PPCR, Boston, MA.

INTRODUCTION
CIA, with an incidence of 65%, is considered by the sufferers as the most emotionally distressing side effect of cancer therapies. Cooling devices, the only option for CIA, have variable efficacy, and requires trained staff. To improve patient’s quality of life, the solution needs to address not only prevention, but also recovery (faster, non-patchy, in original quality) of hair, nails, eyebrows and eyelashes, in a self-medication setting.

Normal hair cycle mainly consists of growth phase (anagen), regression phase (catagen) and resting phase (telogen) that precedes the shedding phase (exogen). The rapidly dividing anagen cells are damaged by chemotoxic agents and undergo apoptosis, inducing premature onset of the apoptosis-driven catagen phase. The intrinsic apoptosis pathway is essentially mitochondria dependent and executed by members of the Bcl-2 family. Androgenetic alopecia (AGA) subjects show remarkably low level of Bcl-2; Moreover p53 knock-out mice do not undergo CIA. These indicate that pharmacological inhibition of apoptosis pathways is key to effectively manage excessive hair loss, including CIA.

In addition, apoptotic cells or cell debris will trigger and sustain scalp inflammatory condition by stimulating production of pro-inflammatory mediators, delaying hair regrowth process. Dampening inflammation is therefore essential to stimulate hair regrowth.

APOPTOSIS MODULATION (STUDY N°1)
OBJECTIVE: To demonstrate the molecular basis for proof of concept and safety through assessment of the candidate’s potential in modulating Bcl-2 towards normal level in AGA subjects.

METHOD: After 3 months’ topical application, analyze, via immunohistochemistry, Bcl-2 level in scalp biopsies of male AGA subjects (n=20), and compare with Bcl-2 in non-AGA volunteers (n=25).

RESULT: AGA subjects' Bcl-2 level is depressed (1.7). The candidate restored Bcl-2 (3.2) towards normal level (4.7).

ATTENUATION OF INFLAMMATION (STUDY N°2)

OBJECTIVE: To test, in vitro, the anti-inflammatory potential of the candidate.

METHOD: To evaluate TNFα-induced expressions of the pro-inflammatory mediators (E-selectin, ICAM-1 and il-8) in endothelial cells (HUVECs) using specific Antibody Binding Capacity (sABC) technology, measured by flow cytometry.

RESULT: The candidate is able to inhibit TNFα-induced expression of inflammatory marker/cytokine: E-selectin, ICAM-1 and il-8 in HUVECs.

OPEN CLINICAL INVESTIGATION (STUDY N°3)

OBJECTIVE & METHOD: To assess the candidate’s efficacy and tolerance, through topical application on female cancer patients, under supervision of oncologists/nurses (n = 11)

RESULT: Candidate showed promising results in faster / non-patchy / original-quality recovery and prevention of CIA. Nail damages were generally prevented.

CONCLUSION AND DISCUSSION
In-vivo and in-vitro studies demonstrate that the candidate normalizes scalp apoptosis, a key to prevent CIA, and attenuates scalp inflammation, a key to promote faster/non-patchy/original-quality hair recovery.

In cancer patients under chemotherapy, the candidate showed promising results in faster/non-patchy/original-quality recovery and prevention of CIA, although a higher dose may be required. Nail damages were prevented.
Title: Weight loss and bone health in postmenopausal breast cancer survivors

Adetunji T Toriola¹, Jingxia Liu¹, Patricia A Ganz², Graham A Colditz¹, Lin Yang¹, Sonya Izadi¹, Anna L Schwartz³ and Kathleen Y Wolin⁴. ¹Washington University School of Medicine, St Louis, MO, Minor Outlying Islands; ²UCLA School of Medicine, Los Angeles, CA; ³Idaho State University, Pocatello, Idaho and ⁴Loyola University College, Chicago, IL.

Body: Background:
The importance of bone health among postmenopausal breast cancer survivors cannot be overemphasized. In addition to bone loss due to aging, secondary bone loss resulting from treatment is a major concern. Although weight loss has adverse effects on bone health in postmenopausal women without cancer, the impact of weight loss on bone health in postmenopausal women with breast cancer is not known. Our objective in this study was to evaluate the effect of weight loss on bone health among overweight/obese postmenopausal breast cancer survivors participating in a weight loss trial.

Methods: We conducted this study in a subset of women (postmenopausal, N=81) enrolled in the multi-site Exercise and Nutrition to Enhance Recovery and Good health for You (ENERGY) study. The ENERGY study is a randomized controlled clinical trial designed to achieve a sustained ≥7% loss in body weight among overweight/obese breast cancer survivors with stage I, II or IIIA disease. Weight loss was achieved largely through dietary modification with the addition of physical activity. Bone health was assessed in a subset of women at a single site using bone turnover markers (BTMs) and dual energy X-ray absorptiometry (DXA). Markers of bone formation: osteocalcin, bone-specific alkaline phosphatase (BALP), procollagen type I N-terminal propeptide (PINP) and bone resorption: N-telopeptides of type-I collagen (NTx), C-terminal telopeptide (CTX) were quantified in blood samples collected at baseline, 6 month and 12-month follow-up. DXA T-score was used to measure bone mineral density at baseline and at 12-month follow-up. Generalized estimating equations were used to assess differences in mean values over time as well as from baseline to 6- and 12-month follow-up. Data from intervention and control arm women were used and treated as a cohort.

Results: The mean age and body mass index (BMI) of women enrolled in our sub-study were 56 years and 31.6kg/m2, respectively. Majority (54.3%) had stage 2 disease. Mean weight decreased by 5.6 pounds between baseline and 6-month follow-up and 4.3 pounds between baseline and 12-month follow-up. There were statistically significant decreases in mean osteocalcin (2.0ng/ml, p-value<0.001), PINP (7.9ng/ml, p-value<0.001) and NTx (3.65nM BCE/L, p-value<0.001), but not BALP and CTX-1 levels between baseline and 12-month follow-up. No significant changes were observed in mean T-scores, pelvis and lumbar spine bone mineral densities between baseline and 12-month follow-up. Weight change from baseline to 12-month follow-up was weakly inversely associated with changes in DXA T-score (r=-0.25, p-value=0.04) and CTX (r=-0.22, p-value=0.07) but not with other BTMs over the same time period.

Conclusion: Weight loss over a 12-month period was associated with decreases in markers of bone formation and resorption but no changes in BMD in overweight/obese postmenopausal women with stage I, II or IIIA breast cancer. Further studies on the association of weight loss and the possible modifying effect of physical activity are needed in order to personalize weight control strategies in overweight/obese breast cancer survivors.
Title: Are physicians "choosing wisely" when imaging for distant metastases in women with early stage (1 or 2) breast cancer? A population study

Demetrios Simos¹, Christina Catley², Carl vanWalraven³, Ian D Graham⁴, Dean Fergusson⁴, Angel Arnaout⁵, Susan Dent¹ and Mark Clemons¹. ¹The Ottawa Hospital Cancer Centre, University of Ottawa, and Ottawa Hospital Research Institute, Ottawa, ON, Canada; ²Ottawa Hospital Research Institute, Ottawa, ON, Canada; ³University of Ottawa, and Ottawa Hospital Research Institute, Ottawa, ON, Canada; ⁴Centre for Practice-Changing Research, University of Ottawa, and Ottawa Hospital Research Institute, Ottawa, ON, Canada and ⁵University of Ottawa, and Ottawa Hospital Research Institute, Ottawa, ON, Canada.

Body: Background: The probability of detecting radiologically evident distant metastases in asymptomatic patients with early stage (stage 1 and 2) breast cancer (BC) is low. Published guidelines, including the 2012 American Society of Clinical Oncology (ASCO) "Top-5" recommendation for "choosing wisely" in oncology, recommend against imaging in these patients. Imaging is also associated with significant false positive results and the need for additional confirmatory imaging and/or invasive procedures. Despite this evidence-base, imaging continues to be over-utilized. We decided to quantify the rates of staging imaging in women with early breast cancer in Canada's largest province to determine whether provincial practice patterns are in keeping with the spirit of the guidelines and the 2012 ASCO "Top-5" recommendation.

Methods: Provincial registry data available through the Institute for Clinical Evaluative Sciences were used to identify all patients with a first diagnosis of stage 1 and 2 breast cancer who underwent breast cancer surgery. For each patient, all imaging of the most common metastatic sites (i.e. skeleton, thorax and abdomen) was captured from the date of diagnosis up until 3 months after definitive breast cancer surgery. Patients who received neoadjuvant therapy or with a prior history of any invasive malignancy were excluded.

Results: Between 2007 and 2012, 27,236 patients with stage 1 and 2 BC were identified. Overall data are shown in the table:

<table>
<thead>
<tr>
<th>Stage</th>
<th>No. of patients</th>
<th>% having at least one imaging test (total)</th>
<th>Total no. of imaging tests (mean per patient imaged)</th>
<th>% of patients imaged who required confirmatory imaging (total)</th>
<th>No. of confirmatory imaging tests performed (% of total imaging)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>14,113</td>
<td>83% (11,713)</td>
<td>40,464 (3.5)</td>
<td>55% (6,420)</td>
<td>11,202 (28%)</td>
</tr>
<tr>
<td>2</td>
<td>13,123</td>
<td>94% (12,330)</td>
<td>53,729 (4.4)</td>
<td>65% (7,983)</td>
<td>16,292 (30%)</td>
</tr>
</tbody>
</table>

The most common initial (i.e. not confirmatory) imaging modalities of the skeleton, thorax and abdomen, for both groups were, bone scan (19%; 12,799/66,699), chest x-ray (28%; 18,789/66,699) and abdominal ultrasound (20%; 13,387/66,699) respectively. Use of advanced imaging (isotope bone scans, CT, MRI, PET) to look at potential sites of metastasis represented 38% (11,063/29,262) and 46% (17,180/37,437) of initial imaging tests in stage 1 and 2 BC patients respectively.

Conclusion: Imaging for distant metastatic disease in patients with stage 1 and 2 BC is commonly performed in Ontario despite multiple guidelines recommending against this. Advanced imaging (isotope bone scans, CT, MRI, PET) is commonly used as the initial imaging modality of choice. Of particular concern is the fact that 60% (14,403/24,043) of BC patients with early stage disease who were imaged required some form of confirmatory imaging. These results show the importance of the recent ASCO "Top-5" recommendation against staging imaging in such patients. The reasons for this disconnect between evidence and practice are not fully understood, but knowledge translation strategies beyond publishing guidelines or recommendations are required if we are to elicit a meaningful and sustained change in physician practice.
Title: Adjuvant radiation after lumpectomy: A cost comparison of treatment patterns in 43,247 women from the National Cancer Data Base

Body: BACKGROUND: Breast cancer treatment contributes the greatest proportion of cancer-related health care spending in the United States. Locoregional therapy comprises a significant share of these costs. We hypothesized that among eligible women with early-stage breast cancer treated with lumpectomy, evidence-based utilization of hypofractionated whole breast radiation or omission of radiotherapy could substantially reduce cancer-related treatment costs.

METHODS: Using the National Cancer Data Base which captures approximately 70% of all newly diagnosed cancers in the United States, we identified 43,247 women with clinically node-negative, T1-T2 invasive breast cancers treated with lumpectomy during 2011. Women with DCIS, those treated with mastectomy, accelerated partial breast irradiation (APBI), or unknown or questionable radiation regimens were excluded. Adjuvant radiation was categorized into the following regimens: conventionally fractionated whole breast irradiation therapy (CF-WBI) [25-40 fractions, 45-66 Gy], hypofractionated whole-breast irradiation (HF-WBI) [15-24 fractions, 40-58 Gy], and lumpectomy without radiation (no RT). Women were considered eligible for no RT if ≥70 years with T1N0, ER+ breast cancers, and for HF-WBI if ≥50 years, with T1-T2 N0 invasive breast cancer. Treatment costs were calculated using Medicare Physician Fee Schedule payment information for 2011, and based on average current procedural codes billed per regimen. Costs per patient were estimated as follows: CF-WBI $13,358.37, HF-WBI $8,327.98, and lumpectomy without RT $0. Actual treatment costs were compared to evidence-based, reduced-cost radiation regimens for which patients were potentially eligible.

RESULTS: Median patient age was 63 years (range 19-90). Median tumor size was 1.2 cm. Of the total study cohort, 84.5% was eligible for HF-WBI, and 22.3% for no RT. Among the 36,562 (84.5%) patients eligible for treatment with HF-WBI, 28,383 (77.6%) received radiation therapy. Of these, 22,653 (79.8%) received CF-WBI, 5,289 (18.6%) received HF-WBI, and 441 (1.6%) received accelerated partial breast irradiation (APBI). Among 9,651 women ≥70 years with ER+ tumors eligible for no-RT, 4,245 (44.0%) received CF-WBI, 1,768 (18.3%) received HF-WBI, 153 (1.6%) received APBI, and 3,485 (36.1%) received no RT. 26% of women received the least expensive evidence-based radiation regimen for which they were eligible, while 67% of patients were treated with more costly radiation regimens. Estimated costs of actual treatment were $420.2 million during 2011, compared to $256.2 million had women been treated with the least expensive radiation regimen for which they were eligible. This translates into an annual cost savings of $164.0 million, a 39% reduction in costs.

CONCLUSIONS: Utilization of evidence-based adjuvant radiation following lumpectomy is associated with reductions in cancer-related costs in the locoregional treatment of early-stage breast cancer. Although treatment decisions should not be driven by health care costs alone, consideration of hypofractionated regimens or omission of radiotherapy for patients that fit evidence-based eligibility criteria could translate into dramatic reductions in annual health care spending.
Title: NSABP B-43 is unlikely to produce a cost-effective treatment strategy for HER2+ DCIS

Michael D Alvarado¹, Mitchell T Hayes¹, Rajni Sethi² and Elissa Ozanne³. ¹UCSF, San Francisco, CA; ²UCSF, San Francisco, CA and ³Dartmouth Institute for Health Policy and Clinical Practice, Hanover, NH.

Body: Background. National Surgical Adjuvant Breast and Bowel Project (NSABP) B-43 is an ongoing randomized clinical trial that compares breast conserving surgery, radiation therapy, and two infusions of trastuzumab to breast-conserving surgery and radiation only for HER2+ ductal carcinoma in situ (DCIS). We sought to identify, from a societal perspective, the level of risk reduction observed in this trial that would be required to make treating HER2+ DCIS patients with trastuzumab cost-effective.

Methods. We developed a Markov decision-analytic model to evaluate these treatment strategies in terms of life expectancy, quality-adjusted life years (QALYs), costs, and the incremental cost-effectiveness ratio (ICER) over 15 years. The results of NSABP B-43 are pending. We therefore assumed the hazard reduction to be 36%, based on the statistical considerations of the trial protocol and explored this in sensitivity analyses. A series of one and two-way sensitivity tests were conducted.

Results. The baseline ICER for switching from a breast-conserving surgery and radiation strategy without trastuzumab treatment to a breast-conserving surgery and radiation strategy with trastuzumab treatment is $1.57 million per life-year gained and $299,616.73 per QALY gained. Compared to a societal willingness-to-pay threshold of $100,000 per QALY gained, adding Herceptin treatment is not cost-effective in the treatment of DCIS under these baseline conditions. In a one-way sensitivity test, we found that the Herceptin strategy only became cost-effective at an 88.3% risk reduction for local recurrence. The model was not sensitive to any costs or probabilities within 20% of baseline values. The model was sensitive to the utilities of having had breast-conserving surgery and radiation with and without trastuzumab treatment. It was not sensitive to other utilities within 0.05 of baseline values.

Conclusions. High risk DCIS treated with breast-conserving surgery and radiation has a low risk of local recurrence as demonstrated in multiple randomized trials. The addition of a costly drug in order to reduce this small risk further is very unlikely to be cost-effective and could be considered overtreatment of a non-fatal disease that is sufficiently managed with local treatment. Prospective cost-effectiveness analyses have the potential to guide allocation of valuable resources for breast cancer research, and should be regularly integrated into the protocol design of large clinical trials.
Title: Post-operative imaging after atypical ductal hyperplasia excision: The findings and costs

Jennifer K Plichta¹, Adrienne N Cobb¹, Gerard J Abood¹, Constantine Godellas¹ and Claudia B Perez¹. ¹Loyola University Health Systems, Maywood, IL.

Body: Introduction: With a reported incidence of 2-12% in breast biopsy specimens, the appropriate management of atypical ductal hyperplasia (ADH) remains in evolution. At present, the optimal screening guidelines for patients with high-risk breast lesions such as ADH remain unclear. Current practices often parallel the surveillance of cancer patients and include a 6 month interval mammogram prior to resuming annual screening, which may result in unnecessary procedures and financial costs. This interval mammogram is typically a diagnostic study, which is an additional cost to the patient and healthcare system. The purpose of this study was to identify interval pathology following initial surgical resection and review associated costs.

Methods: Following institutional review board approval, the pathology database from a single institution was queried for patients who underwent surgical excision for ‘atypical ductal hyperplasia’ from 2008 to 2013. Those who did not have follow-up data available were excluded. Subsequent clinical care was reviewed, including interval imaging and need for additional intervention. Based on a review of hospital charges from 2013, the average charge for a unilateral diagnostic mammogram (out-patient, digital) was $382.

Results: There were 55 patients who underwent an excisional biopsy that were diagnosed with ADH and had subsequent follow-up. The median age was 57 years (range 38-82 years), and the median breast cancer risk assessment score was 2.3% at 5 years (range 0.5-17.9%) and 12.5% lifetime risk (range 2.2-37.6%). Pathology included concurrent lobular carcinoma in situ (n=1), atypical lobular hyperplasia (n=3), flat epithelial atypia (n=14), and papillary lesions (n=19). In addition to a routine clinical breast exam, a short-term follow-up diagnostic (ipsilateral) mammogram was performed in 35 patients. Of the 35 interval mammograms obtained, 31 yielded benign findings on initial imaging, while 4 patients required additional imaging that ultimately resulted in benign findings. The overall hospital charges for the 35 short interval mammograms alone during this 6 year period were roughly $13,370. For the patients that resumed annual surveillance, 3 had abnormal mammograms requiring additional imaging, and no malignancies were identified in this subset of patients. To date, the median physician follow-up is 3 years, and 52 patients have undergone at least one mammogram since their initial imaging; all subsequent findings have been benign for all patients. When extrapolated to national data, cost savings to the healthcare system from eliminating short interval mammograms would exceed $12 million annually without compromising clinical outcomes.

Conclusions: Based on our findings, a 6 month follow-up mammogram is not recommended and incurs unnecessary costs to the patient and healthcare system. In the post-surgical breast, imaging may be misleading and result in additional procedures and significant charges that ultimately do not affect clinical outcomes. Although a clinical exam is still recommended at 6 months following surgical excision for a diagnosis of ADH, patients should forego short interval (6 month) imaging and resume annual mammogram surveillance.
Title: A cost utility analysis from a Chinese health care perspective of Nab-paclitaxel or docetaxel, both as alternatives to solvent-based paclitaxel in metastatic breast cancer (MBC)

George Dranitsaris¹, Bo Yu², Jennifer King³, Adams Zhang³, Satyn Kaura³ and Zhai Qing². ¹Augmentium Pharma Consulting; ²Fudan University Shanghai Cancer Center and ³Celgene Corporation, Summit, NJ.

Body: Background: Paclitaxel and docetaxel are commonly used for the treatment of MBC in China. However, one important drawback, particularly with docetaxel, is the potential for dose-limiting toxicity. To improve the side effect profile and efficacy of paclitaxel, an albumin-bound formulation (nab-paclitaxel) is currently available in China (Abraxane®). To provide health economic data for China, a cost utility analysis comparing nab-paclitaxel to docetaxel, both as alternatives to paclitaxel was conducted.

Methods: Clinical data was obtained from a meta analysis of randomized trials comparing either nab-paclitaxel (260 mg/m² q3wk) or branded docetaxel (100 mg/m² q3wk) to solvent-based branded paclitaxel (175 mg/m² q3wk). Health care resource use for the delivery of chemotherapy and the management of grade 3/4 toxicity was collected from a time and motion study in three Chinese cancer centers, from a survey of clinicians and from the oncology literature. Using the Time Trade-off technique, treatment preferences and utility estimates were obtained from interviewing 28 cancer patients from two centres in China. All costs were reported in 2014 $U.S.

Results: Nab-paclitaxel had the most favourable safety profile characterized with the lowest incidence of grade 3/4 neutropenia, febrile neutropenia, anemia, emesis and stomatitis. This translated to lower costs for managing the grade 3/4 side effects of nab-paclitaxel relative to both docetaxel and paclitaxel ($21 vs. $166 vs. $81) In the preference assessment, 22 of 28 (78.6%) patients selected nab-paclitaxel as their preferred agent. As an alternative to paclitaxel, the incremental cost per quality adjusted life year (QALY) gained was determined to be more favourable with nab-paclitaxel than docetaxel ($57,900 vs. $130,600).

Conclusions: Nab-paclitaxel is an economically attractive alternative to both paclitaxel and docetaxel in MBC patients, providing a substantially lower cost per QALY. Additionally in the patient preference survey, the majority of patients surveyed selected nab-paclitaxel as their preferred agent.
**Title:** Health economic evaluation of: Bevacizumab plus paclitaxel vs. bevacizumab plus metronomic cyclophosphamide and capecitabine as first-line therapy in patients with HER2-negative advanced breast cancer: A multicenter, randomized phase III trial - SAKK 24/09

Klazien W Matter-Walstra, Martin Bigler, Matthias Schwenkglenks, Daniela Bertschi, Jörg Brechbühl, Ursula Hasler-Strub, Roger von Moos, Andreas Müller, Ralph Winterhalder and Christoph Rochlitz. ¹ECPM / University Basel, Basel, Switzerland; ²SAKK Coordinating Center, Bern, Switzerland; ³Cantonal Hospital, St.Gallen, Switzerland; ⁴Cantonal Hospital, Chur, Switzerland; ⁵Cantonal Hospital, Winterthur, Switzerland; ⁶Cantonal Hospital, Luzern, Switzerland and ⁷University Hospital, Basel, Switzerland.

**Body:** Background: Bevacizumab combined with chemotherapy has been shown to improve response rate and progression free survival in metastatic breast cancer. The aim of the health economic analysis (HEA) of this study was to demonstrate that the combination regimen of bevacizumab with cyclophosphamide and capecitabine (metronomic chemotherapy) compared to bevacizumab and paclitaxel treatment decreases overall treatment costs in patients with breast cancer without suffering any losses in effectiveness.

Methods: In this multicenter, randomized phase III trial, we compared bevacizumab (10 mg/kg i.v. q 2 weeks) with either paclitaxel (90 mg/m²) i.v. on days 1, 8, and 15 of a 4 week cycle (arm A) or daily oral capecitabine (3x500 mg) and cyclophosphamide (50 mg, arm B) as first-line treatment in patients with HER2-negative advanced breast cancer. Primary endpoint of the health economic analysis was the total incurred treatment costs until patients stopped trial treatment (time to trial treatment stop (TTS)). TTS was defined as treatment stop due to progressive disease, symptom deterioration, unacceptable adverse events, patient refusal, death or other reasons for withdrawal. The HEA adopted a health system perspective including all substantial direct medical costs incurred in the treatment of the patient. Health-related quality of life was measured by means of the EQ-5D utility instrument. Statistical differences between costs in the treatment arms were tested by the Wilcoxon rank-sum test. A global multivariable linear model, with a gamma distribution and a logarithmic cost transformation was used to analyze the costs for the two arms controlled for age.

Results: Between September 2010 and December 2012, 147 patients were included at 22 centers in Switzerland, 73 (intention to treat (ITT) n=71) in arm A and 74 (ITT n=68) in arm B. The clinical study results will be presented at ASCO 2014. In January 2014, 66 patients in arm A and 63 in arm B of the ITT patients had reached TTS and were analyzed. Mean TTS was 7.3 month in arm A (95%CI 6.3–8.2, median 5.9; quality adjusted mean 5.9, median 5.1) versus 8.5 month (95%CI 6.7–10.2, median 6.8; quality adjusted mean 6.5, median 5.0) in arm B. Total incurred mean costs per patient were CHF 69'474 in arm A (95%CI 60'624–78'324, median CHF 61'815; mean cost per month CHF 10'044) versus CHF 80'324 in arm B (95%CI 62'975–97'672, median CHF 61'751; mean cost per month CHF 10'229). There were no significant differences in costs between the treatment arms and age had no significant effect on the results.

Conclusion: Metronomic chemotherapy plus bevacizumab compared to bevacizumab and paclitaxel treatment showed no substantial reductions in treatment costs. In view of the clinical results the HEA does not favor the metronomic approach. An incremental cost-utility analysis is planned.
Patients’ perspectives on using a genomic test for their breast cancer treatment decisions: Disparities in information exchange

Catherine Chanfreau-Coffinier1, Ninez A Ponce1, Patricia A Ganz1,2, Michele Toscano3, Joanne Armstrong3 and Jennifer S Haas4.
1UCLA Fielding School of Public Health, Los Angeles, CA; 2UCLA Geffen School of Medicine, Los Angeles, CA; 3Aetna, Hartford, CT and 4Harvard Medical School, Boston, MA.

Research Objective
Genomic tests predicting tumor recurrence risk may help inform treatment decisions and improve quality of care. Yet differences in information exchange and patient decision style about genomic tests may further exacerbate disparities in care, particularly if recommendations conflict with patients’ preferences or other prognostic information. This study looks at the information exchange between patients and physicians and patients’ preferences in decision-making in the context of receiving a genomic test for early-stage breast cancer.

Study Design
Retrospective study of women covered by a large national health insurer, who had received the most common, commercial genomic test for early-stage breast cancer prognosis. All eligible minority women (n=705) and a random sample of eligible white women (n=719) matched by age category, geography and diagnosis year, were invited to a mailed survey later linked to claims data. We used random-effects logistic regression models (cluster=state) to examine the association of patient self-reported race/ethnicity with 3 outcomes: 1) knowledge of being tested; 2) patient decision style (assessed with the Control Preference Scale and categorized as active (patient-based), shared, or passive (physician-based); 3) amount of information received on the test. Models were adjusted by patient age, education, income, family structure/support, year of testing, and plan type.

Population Studied
Privately insured women aged 64 years old or less, enrolled for at least 9 continuous months, with an insurance claim for the genomic test in 2009–2012.

Principal Findings
The 62% response rate yielded 896 respondents, including 108 Hispanics, 112 Black, 97 Asians, and 549 whites. 10% of the respondents were unaware that they had received the genomic test, with significant differences in this knowledge by race/ethnicity after controlling for age, education and income (OR= 3.8 for Hispanic and OR = 2.7 for Black women compared to White, both p < .010). Decision style was reported predominantly as active (47%) and shared (40%), and varied significantly with age, income, education and race. In particular, Blacks were more likely than Whites to report a passive rather than shared decision (OR = 1.6; p = .065). Black women were also more likely to rate the information received on the test’s clinical significance as insufficient (OR=2.1; p = .001).

Conclusions
While most women reported more active styles of decision-making, we found significant differences in information exchange that may lower the odds of a well-informed decision for minority patients. Variation in patient reports may reflect variation in understanding and retaining information about the genomic test, or in information delivery by physicians.
Title: Telemedicine: Expanding access to cancer genetic services to underserved populations

Linda Patrick-Miller¹, Diana Harris², Evelyn Stevens², Brian Egleston³, Linda Fleisher², Rebbecca Mueller², Amanda Brandt², Jill Stopfer², Susan Domchek² and Angela Bradbury². ¹University of Chicago, Chicago, IL; ²University of Pennsylvania, Philadelphia, PA and ³Fox Chase Cancer Center, Philadelphia, PA.

Body: Background: Given the increasing demand for genetic services and limited genetic workforce, many patients do not receive recommended pre- and post-test genetic counseling. Telemedicine has been used to expand specialized medical services to low access populations. The feasibility and outcomes of telemedicine in clinical genetics are not well described.

Methods: Patients at 3 community sites without genetic counseling services received real-time pre-test (V1) and post-test (V2) counseling for cancer susceptibility with a genetic counselor (GC) at a center of expertise via community sites’ and host institution’s computers equipped with web cameras and videoconferencing software. Mixed-methods surveys assessed patient knowledge, satisfaction, psychosocial responses and experiences at baseline (BL), post-V1 and post-V2. We used paired T-tests to assess change between time points and linear regressions.

Results: Of 100 patients approached, 83% consented to telegenetic services. To date, 57 have completed BL and V1, and 70% proceeded with genetic testing, 31 patients have received results, including 3 carriers (BRCA2, MSH2, PMS2). Patient characteristics did not differ between those who agreed to and declined telegenetics. 4% of sessions were aborted due to technology failures. 30% experienced disconnections but were completed. Nearly all (94%) were satisfied with their telegenetic experience. Knowledge and satisfaction with telegenetic services significantly increased and general anxiety and depression significantly decreased. Event related (state) anxiety did not change significantly.

Patients reported several advantages to telegenetics (e.g. decreased travel burden) and few disadvantages (e.g. audio challenges and technical glitches). Conclusions: Telemedicine delivery of cancer genetic services is feasible, identifies genetic mutation carriers, increases knowledge, decreases anxiety and depression and is associated with high satisfaction, suggesting an innovative model for delivery of genetic services for patients and community practices without access to local genetic providers.
Title: Receipt of risk reduction strategies among an underserved population of BRCA mutation carriers

Romy Thekkekara¹,², Christina Seelaus¹, Maria O'Connell¹, Elizabeth Marcus¹,² and Pamela S Ganschow¹. ¹Stroger Hospital of Cook County, Chicago, IL and ²Rush University Medical Center, Chicago, IL.

Body: Introduction: Risk reduction strategies for women with deleterious BRCA mutations include risk-reducing mastectomy (RRM) or screening with annual mammograms and MRIs, chemoprevention and prophylactic bilateral salpingo-oophorectomy (RRBSO). The objective of the study was to describe the receipt of various risk reduction strategies in an underserved and largely understudied minority population of BRCA mutation carriers.

Methods: BRCA mutation carriers detected in our center between October 2005 and January 2014 were included in the study. Participants who had bilateral mastectomies prior to genetic testing were excluded from the analysis of breast cancer reduction strategies. Women age 40 or older, with at least one ovary intact at baseline and no history of ovarian malignancy or metastatic cancer were included in the analysis of uptake of RRBSO. Compliance with annual screening mammogram and MRI was defined as receipt of 2 screening mammograms and 2 MRIs within 2 years of the disclosure of the test results. Medical records were reviewed to collect demographic data, personal history of cancer and receipt of mammography, MRI, RRM and RRBSO. Uptake of chemoprevention was not assessed.

Results: Of the 92 BRCA mutation carriers, 89 were women and 3 were men. 35% were Caucasian, 34% were African American and 26% were Hispanic. Sixty eight percent were uninsured and 24% had public insurance. The mean age at the time of testing was 44 years (range: 18-71 years). BRCA1 positivity was seen in 54% and BRCA2 positivity was seen in 46%. Of the 89 women, 7 had bilateral mastectomies prior to testing and 15 were lost to follow up. Among the remaining 67 women, 53 (79%) had a personal history of breast and/or pelvic cancer (affected) and 14 (21%) had no personal history of breast or pelvic cancer (unaffected). Of the 53 affected women, 14 (26%) received RRMs. The median duration from disclosure to RRM was 104 days (IQR: 21- 477 days). Among the 39 affected women who did not undergo RRM, 31 had follow up care at our institution for at least 2 years after disclosure, during which 25 (81%) had at least 2 screening mammograms and 13 (42%) had at least 2 screening MRIs. Among the 14 unaffected women, only 1 (7%) woman underwent RRM. Ten unaffected women had follow up care at our institution for at least 2 years after testing, during which 4 (40%) had at least 2 mammograms and 2 (20%) had at least 2 MRIs. Of the 44 women eligible for RRBSO, 8 (18%) women were lost to follow up. Among the 36 remaining, 23 (64%) underwent RRBSO. Twenty-one out of the 23 who underwent RRBSO had a previous history of cancer. The median duration between disclosure to RRBSO was 170 days (IQR: 90-454 days). Thirteen women (36%) have not yet received the recommended RRBSO after a median follow up of 976 days (IQR:465-1591 days).

Conclusions: Among a diverse group of medically underserved minority women who tested positive for a deleterious BRCA mutation, the receipt of surgical risk reduction strategies and MRI screening is low, especially among women who do not have a personal history of cancer. Additional studies are needed in this population to examine the factors associated with acceptability and compliance with standard of care recommendations as well as institutional barriers to receipt of these risk reduction strategies.
Title: Implementation of cancer risk assessment and genetic testing in underserved patients

Ian K Komenaka¹, Lisa M Winton¹, Jesse N Nodora², Lisa Madlensky², Meredith A Heberer¹, Richard Schwab², Marcia E Bouton¹, Jeffrey N Weitzel³ and Maria Elena Martinez². ¹Maricopa Medical Center, Phoenix, AZ; ²University of California, San Diego, La Jolla, CA and ³City of Hope National Medical Center.

Body: PURPOSE: There is great disparity in genetic testing for breast cancer. Hispanic/Latina women with breast cancer are more likely to have adverse clinical features and have a high prevalence of BRCA mutations. We propose that Academic-Community clinic partnerships offer great potential to provide access to genetic cancer risk assessment (GCRA) for underserved communities, including Hispanic/Latina women. The study also evaluated the willingness of these patients to participate in biospecimen collection.

METHODS: This study assessed the implementation of a limited GRCA and testing service at a safety net institution from July 1, 2011 to December 31, 2013. In the 10 years prior, only two breast cancer patients had undergone genetic testing and both were insured. The inability to perform GCRA was recognized as a critical area of need. Therefore, a breast surgical oncologist received training with City of Hope National Medical Center. The goal is to provide clinicians the appropriate skills to provide GCRA services in areas where these are not available.

Three generation pedigrees and sociodemographic information were collected including health literacy, education, self-reported income, employment status, and insurance status. We conducted a comparison of the patient characteristics along the continuum of GCRA, genetic testing, and mutation carriers, and for the latter group, we describe the BRCA mutation profile.

RESULTS: 125 patients were offered GCRA and all accepted, of which 70% of this patient population was Hispanic and 66% did not have health insurance. Of the 125 patients, 84 (67%) were recommended to undergo genetic testing and 81 (96%) agreed. Of the 81 patients who underwent genetic testing, 68 were also asked to participate in the City of Hope Cancer Screening and Prevention registry and all but one (94%) agreed.

Significant differences between patients who had genetic testing and those who did not were shown for race/ethnicity, insurance, and family history. A higher percentage of Hispanic patients and patients with no insurance underwent testing. Additional trends in differences between patients who were tested vs. those who were not were observed for education and health literacy but these were not statistically significant. Few differences were observed between women who had genetic testing and mutation carriers; however, the number of carriers was too small to merit statistical testing. Twelve of 81 (15%) patients were found to have deleterious mutations, seven BRCA 1 and five BRCA 2. Of the 12 mutation carriers, one patient had ovarian cancer and therefore had already undergone bilateral salpingo-oophorectomy and two others underwent RRSO. Six are either considering RRSO or getting financial assistance for the operation. The last three are still undergoing breast cancer treatment.

CONCLUSION: Results of our experience at a safety net hospital with a largely minority and uninsured population show that limited GCRA and testing can be successfully implemented. The great majority of patients agree to undergo counseling, testing, and participate in biospecimen research registries. Current recommendations for genetic counseling are far from being met across the country and this model could be considered for similar safety net populations.
Title: Women's opinion on when to start screening mammography and reasons for not undergoing screening

Ian K Komenaka¹, Meredith Heberer¹, Jesse Nodora², Chiu-Hsieh Hsu³, Lisa Winton¹, Marcia Bouton¹ and Maria Elena Martinez². ¹Maricopa Medical Center, Phoenix, AZ; ²University of California, San Diego, La Jolla, CA and ³University of Arizona, Tucson, AZ.

Body: Background: In late 2009 significant controversy arose when some screening recommendations were changed to advocate screening mammography starting at age 50 rather than the long standing recommendation of starting at age 40 years. More recently some studies have called into question the benefit of screening mammography. The current study was performed to evaluate patients' opinion on when women should start screening mammography and reasons for not undergoing screening.

Methods: Maricopa Medical Center is the safety net hospital in Phoenix, Arizona. 1,157 consecutive patients were seen at the Breast Clinic from May 2013 to May 2014. Sociodemographic variables were collected including health literacy assessment using the Newest Vital Sign (NVS) validated screening instrument. Patients were asked when they felt women should start screening mammography. In addition, in women at least 40 years of age, if they did not undergo screening mammography, they were asked for the primary reason for not undergoing screening. Differences in patient characteristics were evaluated based on a Fisher's exact test for categorical variables and one-way ANOVA for continuous variables.

Results: Thirteen of the 1,157 consecutive patients were male and excluded. The average age of the 1,144 consecutive female patients was 45 years. Most patients were Hispanic, underinsured, and had limited health literacy. Overall use of screening mammography was poor at only 24%. 402 women (35%) felt that age 40 years was the most appropriate time to start screening. Only 30 women (3%) felt that age 50 years was the most appropriate age. More women, 470 (41%), chose an age younger than age 40 to start screening. More than half (55%) of these women who chose an age 50 years or younger, however, did not undergo screening because they felt they had “no problems” or “didn’t know” they should get a mammogram despite choosing an age to start that was below their current age. Only 187 women (32%) cited cost as the reason for not undergoing screening. Other reasons for not undergoing screening were: physician did not recommend and other medical problems/forgot/too busy. Few patients (4%) cited problems with mammograms for not undergoing screening and none cited concerns about false positives. Multivariate analysis showed that patients with adequate health literacy and insurance were more likely to use screening mammography than patients who were uninsured or had limited health literacy. Family history of breast cancer was not associated with use of screening mammography.

Conclusions: Use of screening mammography was poor in this underinsured population. Most women felt that screening mammography should start at age 40 years or younger. More than half of women who did not undergo screening did not do so because they had "no problems" or "didn't know" they should. Although many women feel that screening should start at age 40, most women in this population do not understand the concepts of screening and early detection. Interventions to increase use of screening mammography should focus on the concept of screening as well as the age.
Title: Mammograms on-the-go: Predictors of repeat visits to mobile mammography vans in St. Louis, Missouri

Bettina F Drake¹, Salmafatima S Abadin¹, Sarah Lyons¹, Su-Hsin Chang¹, Lauren T Steward¹, Susan Kraenzle² and Melody S Goodman¹. ¹Washington University, St Louis, MO and ²Joanne Knight Breast Health Center, The Alvin J. Siteman Cancer Center, St Louis, MO.

Body: Background: Among women, breast cancer is the most common noncutaneous cancer and second most common cancerous cause of death. The American Cancer Society recommends that all healthy women over age 40 have a mammogram annually because early detection and treatment of tumors has been associated with a 15% decrease in breast cancer mortality. African American women have higher mortality rates than white women and, in general, uninsured women have low rates of screening. To increase screening rates, mobile mammography has been implemented in many cities. Previous studies have investigated women’s self-reported adherence to screening guidelines at the time of participation in mobile mammography, but no study has examined if women use it as an annual screening tool.

Objective: The purpose of this study was to determine if women are using mobile mammography vans as their established source of medical care for breast cancer screening and the factors that predict repeat visits to these vans.

Methods: A prospective cohort study was conducted from 2006 to 2013 in which 8450 women who received a mammogram as part of Siteman Cancer Center’s Breast Health Outreach Program responded to surveys and provided access to their clinical records. Only visits on the mammography van were included. The predictor variables explored in this study were: urban status, insurance coverage, age group, race, marital status, mammography experience at baseline visit, employment status, and year of screening. Data were analyzed using chi-square tests, logistic regression, and negative binomial regression.

Results: Among the study participants, 25.3% (N=2134) had multiple visits to the mobile mammography van. Of these women, 57.2% had good mammography experiences at baseline, 48.2% were from urban settings, 70.6% were uninsured, 51.2% were ages 50-65, 69.7% were Black, 76.4% were not currently married, and 63.3% were unemployed. Women who were ages 50-65, uninsured, or Black had a higher odds of a repeat visit to the mobile mammography van compared to women who were ages 40-50, insured, or White (OR=1.135, 95% CI: 1.013-1.271; OR=1.302, 95% CI: 1.146-1.479; OR=1.281, 95% CI: 1.125-1.457), respectively. However, the odds of having a repeat visit to the van was lower among women who reported a rural zip code or were unemployed compared to women who provided a suburban zip code or were employed (OR=.503, 95% CI: .411-.616; OR=.868, 95% CI: .774-.972), respectively.

Conclusion: This study has identified key characteristics of women who are either more or less likely to use mobile mammography vans as their primary source of medical care for breast cancer screening and have repeat visits. It is important that mobile mammography is maintained and remains easily accessible to women who continuously use the service. Further research should be done to discover ways to make mobile mammography a more effective resource for those more likely to use it for routine screening.
Title: Multivariable analysis of repeat utilization of mobile mammography units: 10 year analysis of a comprehensive cancer center

Tezo Karedan, Elizabeth Riley, Lane Roland, Laura Barkley, Jianmin Pan, Shesh Rai and Sarah Mizuguchi. 1University of Louisville, Louisville, KY.

Body: Introduction: Mobile Mammography Units (MMU) are a model of outreach. This study analyzes the association of race, insurance and location to MMU utilization. Our group previously reported these variable as independent predictors of MMU repeat use. This study explores if race, age, insurance and location jointly can predict the utilization of MMU. Methods: From Jan 2001-Dec 2010, 48,324 screening mammograms were performed with 21,587 unique subjects. Demographic data was retrospectively reviewed to identify race/ethnicity, insurance and location for each encounter. Locations were grouped as Corporate (C), Partnership Clinic (PCI), Partnership Community (PCo). Insurance type was classified as Private Insurance (PI), Medicaid (Maid), Medicare (MCare) and Uninsured (UI). Insurance type was classified based on the primary insurer. Utilization was defined as 1x or more than 2x in 10 yrs. Descriptive statistics related to different predictors were produced and statistical comparisons were conducted. P-values were calculated using Chi-square test for comparison between the two groups. Odds ratio and its 95% confidence interval were provided. Logistics regression analysis is used to jointly model the effect of independent factors on repeat utilization of MMU. Reference range for race, insurance and location were chosen based on prior work. Results were declared significant at significance level of 5%. Results: Univariable analysis of race, insurance status, location and age were predictive of repeat utilization of the MMU over a 10 yrs. (p= value <.001, <.001, <.001 <.002) respectively. All variables, race, insurance, location and age remained statistically significant for repeat use in multivariable analysis. Blacks (B) were more likely to repeat compared to Whites (W) and Hispanics (H). MCare patients remained most likely to repeat compared to PI, UI or MCaid patients in multivariable analysis. Location, PCI and Age 50-64 continued to predict for highest utilization rate within the respective cohorts. The estimated OR are shown in Table 1.

Conclusions: To our knowledge this is the reported largest database of MMU. Race, insurance status and location remained independent predictors of repeat utilization. Interestingly an insured subset (MCare) was more likely to repeat utilize the van regardless of race and location. This may reflect the average age of screening mammography however a better understanding of the uninsured subset may be important given the intended outreach of the MMU.
Title: The impact of social inequalities on breast cancer mortality in Brazil

Ruffo Freitas-Junior¹, Carolina M Gonzaga¹, Maria-Paula Curado², Ana-Luiza L Sousa¹ and Marta R Souza¹. ¹Federal University of Goias (UFG), Goiania, Goias, Brazil and ²International Prevention Research Institute (IPRI,), Ecully, France.

Body: Introduction: Female breast cancer mortality has decreased considerably in developed nations. In contrast, an increase has been observed in developing countries. Objective: To describe the impact of social inequalities in female breast cancer mortality in Brazil, between the years of 1990 and 2011. Methods: Breast cancer mortality data and estimates for the resident population were obtained from the Brazilian National Health Service (SUS) database for the 1990-2011 period. Age-standardized mortality rates were calculated (20-39, 40-49, 50-69 and ≥70 years) by direct standardization using the 1960 standard world population. Trends were modeled using linear regression, with mortality rates as the dependent variable and the year of death as the independent variable. The Social Exclusion Index (SEI) and the Human Development Index (HDI) were used to classify the 27 Brazilian states. Pearson's correlation was used to describe the association between the SEI and the HDI and the variations in mortality rates in each state. Results: Age-standardized mortality rates in Brazil were found to be stable (annual percent change [APC] = 0.32; 95%CI: -0.1 – 0.7). Statistically significant decreases in mortality rates were found in the states of Rio Grande do Sul, Rio de Janeiro and São Paulo. Increases in mortality rates were most notable in the states of Maranhão (APC = 11.2; 95%CI: 5.8 – 16.9), Piauí (APC = 9.8; 95%CI: 7.6 – 12.1) and Paraíba (APC = 9.3; 95%CI: 6.0 – 12.8). There was a statistically significant correlation between SEI and a change in female breast cancer mortality rates in the Brazilian states between 1990 and 2011 and between HDI and mortality between 2001 and 2011. This reduction was most notable in the Brazilian states with better socioeconomic conditions. Conclusions: It was observed a direct impact of social inequalities in female breast cancer mortality rates in Brazil. Reductions in these rates were found in the more developed states, possibly reflecting a better local healthcare.
Early discontinuation of adjuvant chemotherapy in women with early stage breast cancer: The BQUAL study

Alfred I Neugut, Grace C Hillyer, Lawrence W Kushi, Lois Lamerato, Jinjoo Shim, Dana H Bovberg, David Nathanson, Christine B Ambrison, Jeanne S Mandelblatt, Carol Magai, Wei Yann Tsai, Judith S Jacobson and Dawn L Hershman.

1Columbia University Medical Center, New York, NY; 2Kaiser Permanente of Northern California, Oakland, CA; 3Mailman School of Public Health, New York, NY; 4Henry Ford Health Center, Detroit, MI; 5University of Pittsburgh Cancer Institute, Pittsburgh, PA; 6Roswell Park, Buffalo, NY; 7Georgetown University, Washington, DC and 8Long Island University, Long Island, NY.

Adjuvant chemotherapy for early stage breast cancer decreases recurrence and increases survival. However, early discontinuation of chemotherapy occurs frequently and has a negative influence on patient outcomes.

METHODS
The Breast Cancer Quality of Care Study (BQUAL) is a prospective cohort study designed to investigate factors associated with early discontinuation of adjuvant chemotherapy among women diagnosed with non-metastatic breast cancer at three sites in the U.S between 2006 and 2010 (Columbia University Medical Center, Kaiser-Permanente of Northern California, Henry Ford Health System). Chemotherapy regimens were classified based on NCCN guidelines. Regimens were further categorized as standard and non-standard/experimental. Early discontinuation for standard treatments was defined as missing 20% of the recommended number of treatments for the prescribed regimen. We used multivariate analysis to examine the association between early discontinuation and sociodemographic factors, tumor characteristics, and baseline psychosocial factors.

RESULTS
Of 1157 women recruited, 478 patients initiated chemotherapy; 35 women received non-standard/experimental chemotherapy and an additional 17 did not complete all interviews and were excluded from the analysis. Of the remaining 426 patients, 59 (13.9%) did not complete the full course of prescribed chemotherapy. In multivariate analysis, compared to those who completed their full prescribed course of adjuvant chemotherapy, those who discontinued were more often >50 years of age (p=0.04). Early discontinuation of chemotherapy was less likely among Asian women (OR 0.12, 95% CI 0.01-0.96), those who held positive beliefs related to the efficacy of chemotherapy (OR 0.43, 95% CI 0.22-0.81), and those who were more optimistic (OR 0.93, 95% CI 0.86-0.99). Women prescribed chemotherapy regimens that had more cycles (>5 cycles) or contained paclitaxel/docetaxel were significantly more likely (OR 7.54, 95% CI 2.68-21.20 and OR 5.02, 95% CI 1.59-15.83, respectively) to discontinue chemotherapy treatment early than regimens with 6 or less cycles.

CONCLUSIONS
Women prescribed longer regimens were significantly more likely not to complete the full course. Positive beliefs about the efficacy of treatment were associated with continuation of treatment. Educational interventions focused on the importance of completing therapy may increase chemotherapy adherence.
Title: Young women with breast cancer: Needs and experiences

Punam Rana¹, Jonathan Sussman¹, Jenna Ratcliffe¹, Margaret Forbes¹, Mark Levine¹ and Nicole Hodgson¹. ¹McMaster University, Hamilton, ON, Canada.

Body: Background
About 11% of all breast cancers in the United States are diagnosed in women younger than the age of 45. Young women with breast cancer (YWBC) may experience unique physical and psychosocial problems. Meeting the needs of these young women is often dependent on a patient’s oncology team. There is a lack of data about the experiences of YWBC in our region including whether their needs are met and which resources are available and offered to them.

Objectives
To explore the unique physical and psychosocial needs of YWBC in our region (Hamilton and Niagara) and to describe what information YWBC receive, and which decisions are made, regarding: fertility, breast reconstruction, mastectomy, sexuality and emotional support.

Methods
This study includes women 40 years of age or less who were diagnosed with invasive breast cancer within 12 months. Using a qualitative design, participants attended a 1 hour focus group or a 30 minute interview moderated by the research coordinator, JR. Recordings were transcribed verbatim, with anonymization of any identifying information. Fourteen participants (ages 30 to 40) were included. Co-PI (PR) and JR reviewed the transcripts, complied recurring categories, and discrepancies were resolved via consensus.

Results
Most participants underwent a timely work-up and diagnosis (64%) but some experienced a delay in diagnosis (37%) as they were seen as unlikely to have cancer due to age. A majority of the participants felt they were provided enough information for informed decisions about treatment. However, over one third of the women were not provided any information about social or community supports and a similar proportion also felt that fertility and sexuality issues were not adequately addressed. Over one third planned on having bilateral mastectomy and/or immediate reconstruction, regardless of physician recommendation. The most distressing aspects of the cancer experience included: telling children and parents about the diagnosis; waiting for test results; fear of recurrence; and re-starting life after breast cancer.

### Conclusion

YWBC feel that they are provided with adequate medical information for treatment decision-making. However, there is a gap in supports for psychosocial, fertility, and sexuality-related needs. Interventions targeted to address these unmet needs should be evaluated. In the second phase of this study, we will create an instrument to further assess the needs of young women with breast cancer in our region.
Title: Enhancing compliance with national nutrition recommendations in breast cancer survivors. Experience in an underprivileged community

Laurent Zelek\textsuperscript{1,2}, Chloe Bodere\textsuperscript{1}, Delphine Bourlier\textsuperscript{1} and Anne Festa\textsuperscript{1}. \textsuperscript{1}Oncologie 93, Bobigny, France and \textsuperscript{2}Avicenne Hospital, Bobigny, France.

Body: BACKGROUND: To enhance compliance with national nutrition recommendations in breast cancer survivors (BCS), a 3-year program granted by the Regional Health Authority began in 2013 in an area (Seine-Saint-Denis, SSD) which is among the poorest in France. Median household income is 68\% lower than in Paris (+68\%), a gap growing with time. Whereas it is widely admitted in France that 25\% of patients are faced with financial difficulties after breast cancer, this proportion reaches 40\% in SSD. We present here intermediate 1-year results.

PATIENTS AND METHODS: Oncologie 93 is a non-profit organization whose aim is to provide supportive care, health education and individualized assistance to patients and families, and to facilitate timely access to quality medical and psychosocial care. Vulnerability was evaluated using an 11-item standardized score (EPICES) previously investigated by French Health Examination Centers. Strictly speaking this score was aimed at measuring precarity, a concept referring to a social condition assumed to face worsening. This score is more strongly related to health status than the administrative classification of poverty (Sass, Sante Publique 2006). Vulnerability was defined by a score $>30$ and considered as severe when $>40$. Between March 2013 and December 2013, 27 BCS were enrolled in a 3-month education program including 3 sessions of a professionally led support group (with dieticians and social workers). Given the high level of poverty in the area and the incidence of financial difficulties in cancer survivors, a particular attention was paid to comparing the costs of different foods in order to promote affordable dietary changes. Mean age was 52. Median vulnerability score was 51.8 (0-93.48) and 64\% of patients had a score $>30$. Dietary intakes were assessed at baseline, and 1 and 6 mos. after the last session. At baseline, although 13 BCS correctly answered the questionnaire, 17 BCS had difficulties to prepare meals and fatigue was the main reason for 10 of them; 4 BCS were lost for follow-up before the end of the program. At 1 mo. 15 BCS had knowledge of healthy dietary choices and 11 were ready to translate it into practice. Of note, 9 BCS decided to enroll in a tailored physical activity program or planned to do it. At 6 mos. only 10 BCS still had knowledge of healthy diet but all of them turned it into practice. Barriers were reported in 10 BCS and included anxiety or depression (n=8), family (n=6) and asthenia or other treatment side effects (n=5).

CONCLUSION: A short-term dietary intervention is feasible in vulnerable BCS living in an underserved area and improves adherence to higher quality diet in a meaningful number of patients. In spite of the attention paid to the affordability of dietary modifications, numerous barriers still exist in this population, mainly related to psychosocial reasons. Furthermore, fatigue negatively influences the ability to prepare meals. A total of 100 BCS will be included over 3 years, and further studies will evaluate the impact of the vulnerability level and psychosocial comorbidities on BCS' compliance.
Title: Religion-related factors and breast cancer screening among American Muslims

Aasim Padela¹, S Murrar¹, S Mallick¹, Z Hosseinain¹, C Liao¹, C Ajax¹, F Marfani¹ and M Peek¹. ¹University of Chicago, Chicago, IL.

Body: Background: Cancer disparities research often overlooks the influence a shared religion may have across race and ethnicity, and thereby misses opportunities to leverage shared religious networks to promote screening. While American Muslims have low rates of mammography and their health behaviors are strongly influenced by religion, a description of such relationships is lacking in the literature. Our study fills this gap.

Methods: We conducted a mixed-methods exploration of how religion-related factors impact breast cancer screening practices. We sampled an ethnically and racially diverse group of Muslim women frequenting mosques and community sites. A survey incorporated measures of fatalism, religiosity, religious discrimination, and Islamic modesty, while subsequent focus groups elicited perspectives on how religious beliefs, values and identity impact breast cancer screening intentions. Survey analyses involved logistic regression models, while focus group data were analyzed using a team-based framework content analysis approach.

Results: Of 240 survey respondents, 72 were Arabs, 71 S. Asians and 59 African Americans. Seventy-five percent had insurance, while 85% had a PCP. 77% reported ever having a mammogram while only 37% a mammogram within the past 2 years. In multivariate models, positive religious coping (OR= 0.21; P < .05) and perceived religious discrimination in healthcare (OR=0.74; P < .05) were negatively associated with having a mammogram in the past two years, while having a primary care physician (OR=20; P < .01) was positively associated. Ever having a mammogram was positively associated with increasing age (OR=1.1; P < .05), years of US residency (10-20 yrs OR=11; 20 yrs OR=4.3; P < .05) and knowing someone with breast cancer (OR=3.5; P < .01). Importantly, ethnic/racial affiliation did not influence mammography rates.

Of 50 focus group participants there were nearly equal numbers of S. Asians, Arabs, and African Americans, 74% reported ever having a mammogram, with 56% having a mammogram within the past two years. Focus group data revealed that family support and encouragement strongly impacted screening intentions, and that obtaining screening in a way that accommodated notions of religious modesty was paramount and prior experiences with such accommodations influenced subsequent intentions. Focus group participants believed that the mosque is a critical community venue for setting religious mores but is underutilized for health education and for motivating theological responses to illness. Participants expressed the need for mosque administration and religious leaders to openly discuss breast health and mammography screening among the Muslim community.

Conclusions: Aspects of religion appear to influence cancer screening behaviors similarly across the socioeconomic, ethnic, and racial diversity of American Muslims. Promoting biennial mammography screening among American Muslims requires addressing ideas about religious coping as related to preventive cancer screening and empowering women to combat perceived religious discrimination. Mosques are underutilized in breast cancer screening interventions but are a ripe setting for religiously-tailored programming that can address barriers to screening and promote a culture of health in this community.
An evaluation of mobile mammography outreach in urban and rural communities

Lauren Steward¹, Susan Kraenzle², Bettina Drake¹, Sarah Lyons¹ and Melody Goodman¹. ¹Washington University School of Medicine, St Louis, MO and ²Alvin J. Siteman Cancer Center/Barnes Jewish Hospital, St Louis, MO.

Background: Mobile mammography has been used to reach underserved women in a diverse number of settings. In this work, we demonstrate similarities and differences between rural and urban communities served by a single mobile mammography unit (MMU) affiliated with a comprehensive cancer center in Missouri.

Methods: An outreach registry of patients serviced by the MMU was created and includes data from medical records and responses to a brief questionnaire completed at each visit. Data was examined by point of care (urban/rural) to assess the efficacy of mobile mammography as an outreach strategy in each of these environments. Bivariate analyses were used to examine the relationships between demographic characteristics such as age, income, race/ethnicity, education, employment status, marital status, insurance status, and living environment proxy.

Results: Between 2006 and 2013, 9480 women received their care on the mobile mammography van. The sample was stratified by point of care (urban vs. rural) served, with majority of the women (86%) residing in urban/suburban St. Louis City/County, and 14% in rural regions. Urban zip codes had a lower percentage of women with income greater than $20,000 (12% v. 21%) and higher percentage of women with income less than $10,000 (49% v. 37%) in comparison to rural communities(p=0.01). There were higher proportions of black women in urban communities (63%) compared to rural communities (10%; p<0.001). Almost half (47%) the women that received mobile mammography in rural zip code were married compared to less than a quarter of women from urban zip codes (24%; p<0.001). Rural communities (83%) had a higher percentage of uninsured women compared to urban communities (67%; p<0.001). Women in urban and rural communities were similar in respect to age, employment status, and education.

Conclusions: Mobile mammography has the potential to reach a large population of women with limited educational, financial, and healthcare resources. Future studies will be needed to determine if increasing the range and extent of mobile units, such as this one, would be effective in increasing the screening rates of not only women in Missouri, but also in other portions of this country.
Evidence-based programs to reduce breast cancer mortality in Panama City

Anna Cabanes¹, Maria Roquebert², Tauane Cruz¹, Blanca Benaglio¹ and Becky Royer¹. ¹Susan G. Komen, Dallas, TX and ²Gestion Social, Panama City, Panama, Panama.

Body: In Panama, as in other Latin American countries, breast cancer is the most common cause of cancer-related deaths among women, and is becoming a major public health problem. Breast cancer mortality rates have steadily risen since 2002 and reflect not only breast cancer incidence and risk factors, but also late-stage diagnosis, quality of cancer care and reduced access to health care.

Susan G. Komen® developed an evidence-based strategic plan for reducing breast cancer mortality focused on increasing access to breast cancer screening and care. Komen’s approach resulted from an analysis of the breast cancer continuum of care in Panama City, aimed at understanding the factors that determine whether women enter the breast cancer continuum of care, and the barriers that prevent women from completing the continuum. Komen utilized the results of the study to drive programs and develop evaluation plans.

We conducted four focus groups and individual interviews with 35 breast cancer survivors living in Panama City to assess the factors that determine access to the breast cancer continuum of care, as well as personal perceptions of breast cancer treatment and follow up. In addition, we held 69 in-depth interviews to capture the community’s perceived barriers in accessing cancer care from three stakeholder groups: public and private medical professionals, non-profits, and private insurers. Interviews and focus groups were audio taped, transcribed and the content analyzed for emergent themes and patterns.

Based on the data, we drafted three different paths of breast cancer care depending on the type of health insurance: Seguro Social (Social security system), private insurance, or no insurance. In all scenarios we identified health care system deficiencies within the primary, secondary and tertiary care levels, in particular low medical breast cancer training and lack of delineated referral guidelines. Community level gaps identified include lack of information, awareness, and social support networks.

To address these gaps, Komen implemented strategic activities that included a program to fund interventions to conduct awareness campaigns, train primary care medical professionals, and reduce barriers to access breast health and cancer care that in Panama is mostly localized in the capital. Impact was measured using an impact chart based on evidence-based and best practice interventions in the areas of public awareness, community and professional education, and continuum of care services. With an investment of $500,000 over two years we were able to reach 2 million people with breast health and breast cancer messaging through 92 television and 268 radio events, and 2,500 views through social media. We funded a total of 36 medical trainings on standard breast health care guidelines by level of care, protocols and referral processes reaching a total of 1,328 medical providers and 65 community leaders, some from indigenous communities (caciques). Finally, we provided housing assistance to 130 women from rural areas that had traveled to receive breast health and breast cancer services, including treatment and follow-up if needed.

Our results show that evidence-based programs provide the opportunity to improve service in areas of most need.
Title: Breast cancer prevention awareness and breast examination attitudes among Hong Kong women who work in a medical environment – A pilot study

Janice Tsang¹, Siu Ting Yung¹, Alston Chiu¹, Henry Sze¹, Cindy Lai Shan Wong¹, Wendy Chan¹, Agnes Cheung¹, Eve Lai¹, Sin Ting Wong¹, To Wai Leung¹ and Dora Kwong¹. ¹Queen Mary Hospital, University of Hong Kong, Hong Kong, China.

Body: Background: Breast Cancer is the commonest female cancer worldwide and the most common female cancer in Hong Kong. Overseas studies have explored the knowledge and attitudes towards breast cancer, but most are targeted at general public. Similar studies were done among female health care personnel but mainly overseas with paucity of data within the Chinese community. This is a pilot study aiming at exploring the breast cancer prevention awareness and breast examination attitudes among Hong Kong women who work in a medical environment. Methods: This is a cross-sectional, qualitative pilot study targeting female nurses working at the Queen Mary Hospital, Hong Kong. We planned for 300 samples as pilot study to validate the questionnaire. This involved self-administrated questionnaires during 1st October 2013 to 30th November 2013. Altogether, 1800 questionnaires were distributed to nurses at Queen Mary Hospital through the Central Nursing Department. Results: A total of 317 completed self-administered questionnaires were collected. The age of the respondents ranged between 20-60, with the majority in the age group of 40-49 (28.4%), followed by 20-29 (27.4%). The mean years in practice was 17. Among the six diseases given for ranking (diabetes mellitus, breast cancer, hypertension, depression, cardiovascular disease, cerebrovascular disease), breast cancer is ranked as the most important disease for their age (37.2%). However, many respondents perceived the degree of risk of breast cancer during their life time to be average (34.1% with median score 5) or even lower (35% under median score 5). The knowledge towards breast cancer risk factor remained limited. Most of them did not identify late menopause (74.5%), advanced maternal age (70.6%) and young age at menarche (58.7%) as risk factors. For breast examinations, most respondents had performed breast self-examination (BSE) (91.2%), less than half of them performed BSE on a regular basis (only 39.4% performed BSE once every month). Ñ The need of my age Ñ (72.2%) and Ñ I am more aware of breast cancer Ñ (54.6%) are claimed to be the major factors encouraging them to perform BSE. Relatively few respondents had ever undergone clinical breast examination (CBE) (41.0%). Similar to the case of BSE, those who had undergone CBE are found to practise it irregularly (23.3%), comparing to 10.1% practising CBE once every year. More respondents with secondary educational level or above had mammography (p=0.000) or ultrasound (p=0.007) done than respondents with primary educational level or below which is statistically significant. Conclusion: The general breast cancer risk awareness among nurses in this pilot study is of concern. There is an unmet need to develop breast cancer preventive intervention program targeting at nurses. This pilot study helps to validate the proposed survey, and serves as the basis for our future design of appropriate intervention to enhance breast cancer awareness and improve early breast cancer prevention for female healthcare workers. Further study is warranted to be extend to female doctors, healthcare assistants and ward clerks etc.
Title: CYP19A1 and ESR1 polymorphisms and selected early-onset side effects during combined endocrine therapy in the IBCSG TEXT trial for premenopausal women with hormone receptor-positive (HR+) early breast cancer

Harriet Johansson¹, Kathryn P Gray², Olivia Pagani³, Meredith M Regan², Giuseppe Viale¹, Valentina Aristarco¹, Debora Macis¹, Antonella Puccio¹, Susanne Roux⁴, Rudolf Maibach⁴, Marco Colleoni¹, Manuela Rabaglio-Poretti¹, Alan S Coates⁵, Richard D Gelber², Aron Goldhirsch¹, Roswitha Kammler⁴, Bernardo Bonanni¹ and Barbara A Walley⁶. ¹European Institute of Oncology, Milan, Italy; ²IBCSG Statistical Center, Dana-Farber Cancer Institute, Boston, MA; ³Institute of Oncology of Southern Switzerland, Lugano Viganello, Switzerland; ⁴IBCSG Coordinating Center, Bern, Switzerland; ⁵International Breast Cancer Study Group, Sydney, Australia and ⁶NCIC Clinical Trials Group, Kingston, ON, Canada.

Body: Background: Single nucleotide polymorphisms (SNPs) of the aromatase enzyme (CYP19A1) and estrogen receptor alpha (ESR1) may be associated with breast cancer susceptibility and endocrine-mediated side effects. The IBCSG Tamoxifen (Tam) and Exemestane (Exe) Trial (TEXT) includes a translational research project to assess whether selected SNPs may influence treatment efficacy and toxicity. We report on early-onset hot flashes and sweating (HF/S) and musculoskeletal symptoms (MS; myalgia, arthralgia, stiffness) with respect to CYP19A1 and ESR1 SNPs under combined endocrine therapy.

Patients and Methods: 2,672 premenopausal women with HR+ early breast cancer were randomized to treatment with the GnRH-agonist triptorelin (Trip)+Tam or Trip+Exe for 5 years. Randomization was stratified according to intended use of chemotherapy (yes/no) and lymph node status (N- vs N+). Estrogen-depletion side effects (HF/S and MS) were recorded at baseline, 3-monthly during the first year and 6-monthly thereafter using the NCI CTCAE v3.0. DNA was centrally extracted from whole blood with Qiagen kits. SNPs of CYP19A1 (rs4646 and rs10046) and ESR1 (rs207764, rs2234693 and rs9340799) were analyzed by a pyrosequencing method (Diatech Pharmacogenetics S.r.l., Jesi, Italy). Control genotypes (wt/wt; wt/v; v/v) for all SNPs were processed in each run. Logistic regression was used to analyze two endpoints: presence or absence of grade (gr) 2-3 HF/S during first 6 months and gr 2-4 MS during first 12 months. Four genetic models were used to explore associations with side effects: genetic (wt/wt; wt/v; v/v), additive, dominant and recessive.

Results: DNA was isolated and genotyped for 1970 (74%) consenting women. Clinical characteristics and outcomes of this cohort were consistent with the overall trial. At baseline median age was 44, median BMI 24 kg/m2 and 86% had regular menses. During follow-up, 43% reported gr 2-3 HF/S and 27% reported gr 2-4 MS. The 5 SNPs did not deviate from Hardy-Weinberg equilibrium (p>0.30) and minor allele frequency ranged from 29%-48%. The CYP19A1 SNP rs10046 (C>T) was associated with gr 2-3 HF/S. Specifically, women with variant homozygote genotype (T/T) had a reduced risk of HF/S (39% T/T vs 45%). The univariate odds ratio (OR) was 0.77 (95%CI: 0.62-0.96; p=0.02) compared with other variant groups. The multivariate model showed consistent results after adjusting for age, BMI, menstrual status, chemo use, treatment allocation (Tam vs Exe) and baseline HF/S. The other 4 SNPs were not associated with the selected side effects.

Conclusions: Our analysis indicates association of HF/S with CYP19A1 rs10046 genetic variants. The lack of association between early-onset of selected estrogen-depletion side effects and the other 4 SNPs may be masked by the concurrent Trip. Ovarian reserve before treatment may also influence the impact of SNP genotypes on early-onset side effects. Further analysis with details of concurrent medications and treatment adherence will contribute to the interpretation of these results.

Title: Effect of using LHRH analog during chemotherapy (CT) on premature ovarian failure and prognosis in premenopausal patients with early-stage, hormone receptor-positive breast cancer: The primary analysis of a randomized controlled phase III trial

Jian-Wei Li¹, Guang-yu Liu¹, Ke-Da Yu¹, Ya-jie Ji¹, Miao Mo², Li Lei³, Jiong Wu¹, Gen-hong Di¹, Yi-feng Hou¹, Zhen Hu¹, Can-ming Chen¹, Zhen-Zhou Shen¹ and Zhi-Ming Shao¹. ¹Cancer Center and Cancer Institute, Shanghai Medical College, Fudan University, Shanghai, China; ²Cancer Center and Cancer Institute, Shanghai Medical College, Fudan University, Shanghai, China and ³The First People's Hospital of Kunming, Kunming, Yunan, China.

Body: Background: Whether administration of LHRH analog during CT in premenopausal patients with early-stage, hormone receptor-positive disease would reduce CT-induced premature ovarian failure (POF) is still controversial. Moreover, whether LHRH analog would influence the prognosis of patients is unknown yet. This randomized study is to evaluate whether administration of LHRH analog during CT would reduce POF and effect the prognosis of breast cancer.

Methods: This is a randomized, controlled phase III clinical trial. Premenopausal patients age <46 with stage I-IIIA, ER/PR-positive BC to be treated with CT were randomized into two arms. Concurrent arm received CT with goserelin (GN) 3.6 mg SQ starting 0-7 days prior to the first CT dose, and after CT, the researchers determined whether continuous GN to 2-5years or cessation. Sequential arm received CT without GN, and after CT, the researchers determined GN 2-5 years immediately or after restoration of ovarian function or bilateral ovariectomy. Neoadjuvant CT was allowed. Five-year tamoxifen after CT was administered to all patients. The primary endpoint is POF, defined as amenorrhea for the prior 12 months and post-menopausal FSH or not assessed after last CT dose or last GN dose. Other endpoints include efficacy of neoadjuvant CT and relapse-free survival (RFS), defined as time to the first of these events: loco-regional recurrence, contralateral breast cancer or distant metastasis.

Results: Between 2/09 and 5/13, the trial has finished enrollment, 216 patients were enrolled. The median age were 37.5 in combined arm (n=108) and 39 in sequential arm (n=108), respectively. The median follow-up time was 27.4 months and 25.7 months, respectively. 15 patients and 21 patients received neoadjuvant CT, respectively. There were no significant difference in age, tumor stage and CT regimens (p>.05). The median cycles of GN were 25, respectively. 47% had complete primary endpoint data. POF rate were 5/42 (11.9%) in the combined arm and 16/60 (26.7%) in the sequential arm. POF rate (and post-menopausal FSH) rate were 1/42 (2.4%) in the combined arm and 8/60 (13.3%) in the sequential arm. In neoadjuvant CT subgroup, each has 1 patient achieved pathological complete remission, and there was no significant difference in objective clinical response. There were 9 patients in the combined arm and 3 patients in the sequential arm had occurred RFS events (including 2 and 0 deaths, respectively, OR=3.18, 95%CI:0.84-12.09, P=.075).

Conclusions: LHRH analog administration with CT might be associated with less POF and did not affect the efficacy of neoadjuvant CT, however, had no RFS benefit, it may need longer follow-up. We will conduct an interim analysis in November 2014.

**Body:** Background: Adjuvant five-year treatment with aromatase inhibitors is standard for postmenopausal women with estrogen receptor positive breast cancer. However, aromatase inhibitor-related adverse events including joint symptoms and vasomotor symptoms have a strong impact on patients’ quality of life and sometimes result in treatment discontinuation. The aim of this study is to determine risk factors for discontinuation of endocrine therapy in Japanese postmenopausal breast cancer patients treated with adjuvant anastrozole in a prospective cohort study based on patient-reported outcomes (PROs).

Patients and Methods: A total of 391 postmenopausal Japanese women with estrogen receptor-positive breast cancer and treated with adjuvant anastrozole were enrolled from 28 centers in this prospective cohort study (SAVS-JP, UMIN000002455). PROs assessment was obtained at baseline, 3, 6, 9 and 12 months which included joint and vasomotor symptoms. Long-term adherence of anastrozole was obtained from 364 out of 391 patients (median follow-up: 44 months, range: 5-105months). We analyzed the relationship of discontinuation of anastrozole with joint and vasomotor symptoms induced by treatment, and patients’ characteristics.

Results: Among 364 patients, 64 (17.6%) discontinued, 297 (81.6%) are ongoing and 3 (0.8%) have completed five-year anastrozole treatment. The reasons for discontinuation were recurrence: 20 (31.3%), secondary malignancies: 5 (7.8%), death from non-breast cancer: 1 (1.6%) and adverse events: 38 (59.4%). These 38 patients who stopped treatment caused by adverse events were compared with other 323 patients. Joint and vasomotor symptoms were categorized into grade 0 (no symptom or no change from baseline), grade 1+2 (mild-moderate) and grade 3 (severe). Grades of joint symptoms were significantly associated with discontinuation of anastrozole (Grade 0: 9.7%, grade 1+2: 7.8%, grade 3: 25.0%, p=0.02). Patients with longer time after menopause (16 years or longer) were significantly higher frequency of discontinuation as compared with shorter time after menopause (0-15years) (14.9% vs 8.0%, p=0.04). Univariate analysis revealed that grade 3 joint symptoms (odds ratio: 3.67, 95% confidence interval: 1.34-10.04, p=0.01) and longer time after menopause (OR: 2.01, 95%CI: 1.01-4.00, p=0.04) were significant risk factors for discontinuation. By multivariate analysis, both grade 3 joint symptoms and long time after menopause were independently associated with discontinuation.

Conclusion: In the present study, we have identified that grade 3 joint symptoms and longer time after menopause were risk factors for discontinuation of adjuvant anastrozole. These data might give us useful information for counseling in patients with adjuvant aromatase inhibitors for postmenopausal Japanese women.
Title: Aromatase inhibitor induced musculoskeletal syndrome (AIMSS) in Australian women with early breast cancer: An Australia and New Zealand Breast Cancer Trials Group (ANZBCTG) survey of members of the Breast Cancer Network Australia (BCNA)

Janine M Lombard\textsuperscript{1,2,3}, Nicholas Zdenkowski\textsuperscript{1,2,3}, Kathy Wells\textsuperscript{4}, Nicca Grant\textsuperscript{4}, Linda Reaby\textsuperscript{3}, John F Forbes\textsuperscript{1,2,3} and Jacquie Chirgwin\textsuperscript{2,3,5}. \textsuperscript{1}Calvary Mater Newcastle, Newcastle, NSW, Australia; \textsuperscript{2}University of Newcastle, Newcastle, NSW, Australia; \textsuperscript{3}Australia and New Zealand Breast Cancer Trials Group, Newcastle, NSW, Australia; \textsuperscript{4}Breast Cancer Network Australia, VIC, Australia and \textsuperscript{5}Monash University, VIC, Australia.

Body: Background: AIMSS is experienced by approximately half of women taking an aromatase inhibitor (AI), impairing quality of life and in some leading to AI discontinuation. There is a lack of evidence for effective AIMSS treatments. Aim: To investigate the importance of AIMSS in Australian women with early breast cancer. Method: A survey invitation was distributed to 2390 members of the BCNA Review and Survey Group in April 2014. The online questionnaire consisted of 45 questions covering demographics, AI use, clinical manifestations and risk factors for AIMSS, reasons for AI discontinuation and efficacy of interventions used for AIMSS. AIMSS was defined as joint pain or stiffness that developed or worsened after commencing an AI. Results: Of 594 respondents, 370 (62\%) were eligible. Reasons for exclusion were: preinvasive disease, locally advanced/metastatic breast cancer, or other reason. Eligible respondents had a median age range of 50-59 years. Duration of AI use varied (26\%1 year, 64\% 1-5 years, 10\% 5 years). 57\% had received adjuvant chemotherapy. 43\% of these commenced AI within 3 months of chemotherapy and 30\% within 3-6 months of chemotherapy. A vitamin D test was performed in 64\% of women and 68\% were currently using vitamin D supplements. Joint pain during menopause was reported by 22\% of respondents. AIMSS occurred in 302/370 women (81\%). Of those who developed AIMSS, sites affected were feet (68\%), hands or wrists (65\%), knees (62\%), hips (56\%), shoulders or elbows (49\%), back (46\%), or neck (3\%). 34\% of women had considered stopping an AI because of AIMSS. 99 (27\%) of respondents had discontinued AI for any reason and of these 68\% discontinued because of AIMSS. Non-AIMSS symptoms identified as reasons for discontinuation included fatigue, vaginal/urinary symptoms and hot flushes. In respondents who discontinued AI, 20\% ceased use in the first 3 months, 30\% during months 3-12 and 38\%12 months. 42\% of respondents who discontinued an AI restarted the same or a different AI after a treatment break. To manage AIMSS 23\% of respondents used doctor prescribed medications (eg anti-inflammatories, codeine, morphine,), 55\% over the counter (OTC) or complementary medicines (eg low dose anti-inflammatories, paracetamol, chondroitin, fish or krill oil, glucosamine, and vitamin D) and 29\% alternative therapies (eg acupuncture, massage, Tai Chi and yoga). Respondents identified the following in each of the above categories as most successful in relieving AIMSS symptoms: doctor prescribed anti-inflammatories, paracetamol and yoga. Doctor prescribed medications and OTC/complementary medicine either completely or significantly relieved AIMSS in 12\% and 25\% of cases respectively. 27\% of respondents found that one or more of the interventions that they had used to manage AIMSS helped prevent AI discontinuation. Conclusion: AIMSS is a significant issue for Australian women and is an important reason for AI discontinuation. Women use a number of interventions to manage AIMSS, however their efficacy appears limited. Effective AIMSS interventions are needed, to improve quality of life and reduce AI discontinuation.
Title: Co-SOFT: The cognitive function substudy of the suppression of ovarian function trial (SOFT)

Body: Background: Cognitive impairment is a potential side-effect of breast cancer (BC) treatment. Estrogen is an important neuromodulator that affects cognition. Estrogen depletion by oophorectomy or GnRH agonists may adversely affect cognition in non-oncological settings, but there are few data regarding the cognitive effects of ovarian function suppression (OFS) in women with breast cancer.

Patients and Methods: Between November 2003 and January 2011, 3066 premenopausal women with hormone receptor-positive BC were randomised on the SOFT trial to 5 years of adjuvant endocrine therapy with tamoxifen alone, tamoxifen+OFS or exemestane+OFS. OFS was achieved by the GnRH agonist triptorelin, oophorectomy or ovarian irradiation. Prior chemotherapy was allowed, provided women had premenopausal estradiol levels at enrolment. Women eligible for Co-SOFT must not have received any prior adjuvant endocrine therapy. At study entry (t1), and approximately 1 year after SOFT randomisation (t2), objective cognitive function was assessed with a brief computerized test battery comprising 7 tasks (CogState Ltd: cogstate.com). Subjective cognitive function, psychological distress, fatigue, insomnia and quality of life were also assessed. Co-SOFT recruited 86 of a planned 321 patients from 27 of 426 SOFT centres between November 2007 and January 2011, when Co-SOFT was closed as the SOFT trial completed accrual. The protocol-specified primary comparison was the change in the composite score of the CogState tasks over 1 year for women randomised to tamoxifen alone compared with OFS+oral endocrine therapy. However, due to low accrual this was modified, prior to any analysis, to compare the tamoxifen versus the pooled tamoxifen+OFS and exemestane+OFS groups.

Cognitive test scores were standardized according to age-specific norms, averaged to compute the composite score and then change between t1 and t2 calculated; a negative change in composite score indicates deterioration in cognitive function. Change in composite score was compared using Wilcoxon rank sum test.

Results: Of 86 Co-SOFT enrolled patients, 74 underwent both t1 and t2 CogState testing and were included in the primary analysis (7 withdrew consent/declined assessment, 5 missed testing due to scheduling). Of these 74 women, 20 were randomised to tamoxifen and 54 to OFS+tamoxifen (28) or OFS+exemestane (26). Baseline characteristics were well balanced between the 2 groups. During the first year 49 women utilised GnRH alone for OFS, 4 had GnRH followed by oophorectomy and 1 had oophorectomy alone. There was no significant different in the changes in the CogState composite scores from t1 and t2 for patients randomised to tamoxifen alone compared with OFS+oral endocrine therapy (median, -0.057 versus -0.146 respectively, p=0.51). There were no significant between-group differences in the changes from t1 and t2 for any of the 7 individual cognitive tasks comprising the composite score.

Conclusions: The results of this 1-year longitudinal substudy suggest that the addition of OFS to oral endocrine therapy does not significantly affect cognitive function in the setting of adjuvant BC treatment. Co-SOFT was limited by small sample size, so further investigation of the impact of OFS on cognitive function in BC patients is warranted.
Title: Characteristics of recurrence after completing adjuvant tamoxifen therapy for 5 years

Eunshin Lee¹, Han-Byoel Lee¹, Young Joon Kang¹, Yun-Gyoung Kim¹, Tae-kyung Yoo¹, Jongjin Kim¹, Min Kyoon Kim¹, Hyeong-Gon Moon¹, Dong-Young Noh¹ and Wonshik Han¹. ¹Seoul National University College of Medicine, Seoul, Korea.

Body: Background Treatment with tamoxifen (TMX) reduces the recurrence rate and increase overall survival in patients with hormone receptor positive breast cancer. Up to now, 5-year TMX therapy is generally accepted, but it is demonstrated that the rate of late recurrence after 5 years is considerably higher in hormone receptor positive type than in other subtype. Several clinical trials such as ATLAS and aTTom showed the benefit of continuing tamoxifen up to 10 years instead of stopping at 5 years without increasing mortality due to the effect of extended tamoxifen medication.

Method We collected data of 1633 hormone receptor positive breast cancer patients who received surgery at Seoul National University Hospital from 1997 to 2007, and had completed 5-year TMX therapy with no recurrence within 5 years after diagnosis. Mean age of the patients was 43.3, and the patients have estrogen receptor or progesterone receptor. We included from the stage I to stage IV patients underwent curative surgery and received adequate adjuvant therapy such as chemotherapy or radiation therapy after surgery. We excluded the cases treated aromatase inhibitor (AI) or switched to AI.

Result Among these patients, recurrences after 5 years of TMX therapy were found in 93 patients (late recurrence group). Local recurrences and distant metastases were found in 43 and 50 patients, respectively. Electronic medical records were retrospectively reviewed for clinicopathological factors. When comparing between patients with no recurrence and patients with late recurrence, p53 and HER-2 expression were significantly related to late recurrence (p=0.01, p<0.001 respectively). Also when subgroup analysis was done for distant metastasis of late recurrence group, distant metastasis was significantly associated with HER-2 expression and high nuclear grade (p=0.005, p=0.006 respectively). There are no relation between late recurrence and age, stage and ki-67.

Conclusion our data shows that p53 and HER-2 expression is associated to late recurrence and especially HER-2 expression is related to distant metastasis after completing TMX for 5 years. On the basis of the result of large clinical trials, extending TMX therapy significantly reduces recurrence rate and increase survival. Our result support continuing TMX in patients with HER-2 expression and high nuclear grade is considerable after 5 years of TMX medication.
Title: Bortezomib enhances the efficacy of fulvestrant by promoting the aggregation of the ER in the cytoplasm

Doris Germain¹, Kerin Adelson², George Raptis³ and Samuel Waxman¹. ¹Icahn School of Medicine at Mount Sinai; ²Yale University School of Medicine, New Haven, CT and ³North Shore-LIJ Cancer Institute.

Body: Background: Aromatase inhibitors (AIs) are standard treatment for Estrogen Receptor (ER)+ breast cancers in post-menopausal women where the main source of estradiol comes from adipose tissue when the aromatase enzyme converts androgens to estrogens. However, in premenopausal women, functioning ovaries flood the body with estrogens, and aromatase inhibitors used alone offer no therapeutic benefit. In addition to tamoxifen and aromatase inhibitors, estrogen receptor down-regulators, are a third type of anti-estrogen. The first of this class to be FDA approved is Fulvestrant, which acts by promoting the proteosomal degradation of the ER. Like tamoxifen, fulvestrant binds directly to the ER but while tamoxifen has both antagonist and agonist effects on the ER, fulvestrant is a pure antagonist. Other important advantages of fulvestrant over tamoxifen are that 1) fulvestrant prevents the ER from binding DNA, 2) fulvestrant is not linked to increased risk of endometrial cancer, 3) fulvestrant promotes permanent degradation of the ER.

The molecular machinery leading to the degradation of the ER in the nucleus following fulvestrant treatment is well described and correlates with its ubiquitination in the nucleus. A less well-recognized mechanism, is fulvestrant’s ability to promote the aggregation of the newly synthesized ER in the cytoplasm. Understanding that protein aggregates are toxic when not eliminated by the proteasome, we took advantage of this effect of fulvestrant to ask whether combining fulvestrant with the proteasome inhibitor Bortezomib could enhance the efficacy of Fulvestrant.

Results: We found that bortezomib enhances the aggregation of the ER in the cytoplasm following treatment with fulvestrant. Further, these aggregates were found to be insoluble and to activate the unfolded protein response (UPR), a stress response that leads to cell death. Further, bortezomib is able to prevent the activation of cytoprotective responses linked to the acquisition of fulvestrant resistance. Furthermore, in a breast cancer mouse model of tamoxifen resistance, the combination induced tumor regression. We currently are testing new generation proteasome inhibitors and the results will be presented at the meeting.

Conclusion: We conclude that adding bortezomib to fulvestrant enhances its efficacy by taking advantage of a previously poorly recognized mechanism—fulvestrant’s induction of ER aggregation in the cytoplasm. Further, our data suggest that this strategy will block the ability of cells to acquired resistance to fulvestrant. Our group has developed a clinical trial that has tested this combination and the results of this trial presented at the meeting.
Title: Possibility of GnRH agonist plus tamoxifen as an alternative treatment to AC (adriamycin plus cyclophosphamide) chemotherapy plus tamoxifen treatment in premenopausal hormone responsive HER2 negative breast cancer patients

Heeseung Park¹, Guiyun Sohn¹, Byung Ho Son¹, Jong Won Lee¹ and SeiHyun Ahn¹. ¹College of Medicine, University of Ulsan, Seoul, Korea.

Body: Background: The purpose of this study is to compare the treatment outcomes using GnRH agonist plus tamoxifen, and adriamycin and cyclophosphamide (AC) containing chemotherapy plus tamoxifen in hormone responsive premenopausal node negative breast cancer patients.

Methods: Total 1027 premenopausal women with node negative, hormone receptor positive, Her-2 negative breast cancer were included in this retrospective cohort study. 595 patients (57.9%) were treated with GnRH agonist together with tamoxifen, and 432 patients (42.1%) were treated with adriamycin and cyclophosphamide containing chemotherapy with tamoxifen.

Results: A median follow up period was 81 months. In pT1 disease, 7 year DFS (disease free survival) was 98.9% for GnRH agonist plus tamoxifen group and 97.4% for chemotherapy plus tamoxifen group, and in pT2 disease, 7 year DSS was 99.1% for GnRH agonist plus tamoxifen group, and 96.9% for chemotherapy plus tamoxifen group with no statistical significance (p=0.252 & 0.230). In pT1 disease, 7 year RFS was 95.4% for GnRH agonist plus tamoxifen group and 92.9% for chemotherapy plus tamoxifen group, and in pT2 disease, 7 year RFS was 91.6% for GnRH agonist plus tamoxifen group, and 91.7% for chemotherapy plus tamoxifen group with no statistical difference between two treatment groups (p=0.353 & 0.836). In subgroup analysis, ER+/PR+ patients and patients younger than 40 years old showed slightly better survival in GnRH agonist plus tamoxifen group when compared to chemotherapy plus tamoxifen group with p-value of 0.046 & 0.018.

Conclusion: Adding GnRH agonist to tamoxifen is reasonable alternative to adding AC chemotherapy to tamoxifen in premenopausal luminal type node negative breast cancer patients.
Title: Tamoxifen treated patients have a better survival than patients treated with aromatase inhibitors - A population based registry study in Sweden

Håkan Olsson¹,², Rickard Einefors¹ and Per Broberg¹. ¹Clinical Sciences, Lund University, Lund, Sweden and ²Lund University, Lund, Sweden.

Body: Background. Randomised trials suggest that therapy with aromatase inhibitors improves survival in breast cancer compared with tamoxifen therapy in postmenopausal cases with hormone receptor positive breast cancer. Whether these results from randomized studies transform into the general population is unknown. We have therefore compared survival for all breast cancer cases in Sweden diagnosed 2000-2008 (n=54406) who received adjuvant antihormonal therapy.

Material and methods. The study includes all women with BC diagnosed in Sweden between 2000 through 2008 (n=54406). The women had no previous cancer diagnosis during the period of 1958-1999. Dates of birth, BC diagnosis and TNM-stage were directly extracted from the cancer registry. The women’s antihormonal therapy was gathered from the Swedish Prescription Registry (22213 women were on antihormonal therapy). Information regarding the cause of death and date of death was obtained from the Cause of Death Registry and the Swedish Population Register up until the 31st of December 2012 and 31st of December 2013 respectively. The breast cancer death and overall death have been calculated and the survival was compared between tamoxifen and aromatase inhibitor treated breast cancer patients. Analyses were adjusted for TNM-stage and age at diagnosis and restricted to women aged 50 and above.

Results. Patients being treated with tamoxifen had a better breast cancer prognosis compared with aromatase inhibitor treated patients (HR 0.54, 95%CI 0.48-0.61). Restricting the analysis to stage 1 disease confirmed a better prognosis for tamoxifen treated women (HR 0.48, 95%CI 0.34-0.66). A better prognosis could be seen in all age strata studies, 50-60,61-70,71-90. The findings for overall survival gave similar results.

Conclusion. This population based observational study show that women treated with aromatase inhibitors have a worse overall and breast cancer specific survival compared with tamoxifen treated women regardless of age and tumor stage.
Title: Prospective study of aromatase inhibitor-induced bone loss and lipid levels in early hormone sensitive breast cancer treated with AI during 8 years

Christel Fontaine¹, Lore Decoster¹, Denis Schallier¹, Leen Vanacker¹, Jacques De Grève¹, Marian Vanhoeij², Guy Verfaillie² and Jan Lamote². ¹Oncologisch Centrum, UZ Brussel, Jette, Brussels, Belgium and ²Breast Surgery, Oncologisch Centrum, UZ Brussel, Jette, Brussels, Belgium.

Body: Introduction: AI’s are the preferred adjuvant hormonal treatment for postmenopausal(PM) estrogen receptor positive (ER+) disease because of the improved efficacy over tamoxifen in terms of disease free survival and reduction in distant recurrence. AI’s have been associated with increased bone loss by blocking peripheral tissue estrogen synthesis, arthralgia and a negative effect on lipid metabolism. In this prospective study we wanted to assess the amount of bone loss and the changes in lipid levels in early breast cancer(EBC) patients (pts) treated with 3yrs of extended letrozole as part of the SOLE study after 5 yrs of adjuvant AI. Objectives: the primary objective of the study is to calculate the mean percentage change in bone mineral density(BMD)(g/cm²) after 8 yrs of letrozole and to compare between the continuous(C) and intermittent(I) intake of letrozole. The secondary objectives are to correlate the mean change in BMD with the initial value, BMI and to describe the evolution of the lipid levels in both groups. Patients and methods: BMD was measured at the lumbar spine (L2-4) and hip by dual energy X-ray absorptiometry (DEXA) in PM pts. with ER+ EBC. We also measured the fasting lipid levels baseline and after 8 yrs of an AI. Differences between the two groups were assessed by the independent samples T-test and the correlation by the linear regression analysis. Results: Fifty four pts were included in the study with a mean age of 62.5 yrs(+/−8.6 yrs). Seventeen pts are too early to be evaluable, 8 pts stopped letrozole due to adverse events and 2 pts had no baseline DEXA values. Two pts received tamoxifen 2 to 5 yrs before inclusion in the SOLE study. The remaining 25 pts showed a mean change in BMD for the lumbar spine of -1.1 (10.6SD) and for the hip -4.4 (7.04SD). Currently 13 pts in the C arm demonstrated a mean decrease in BMD for the (LS) of -2.7(10.2SD), and for the hip -4.4 (7.04SD). Twelve pts included in the I arm experienced a mean increase in BMD for the LS of 0.65(SD11.2) and a mean decrease in BMD for the hip of -4.9(9.1SD). The difference between the two treatment groups was not significant for the LS measurements after 8yrs (p=0.4) nor for the hip (p=0.23) neither was it at baseline (p=0.9; 0.1). Only three pts had fractures due to trauma. The overall fracture rate was only 0.05%.There was no correlation with the BMI, but there was a significant correlation with baseline BMD.(p=0.002)The mean fasting cholesterol levels at 8yrs in the C arm was 214mg/dl(41.3SD) and in the I arm was 218mg/dl(35.6SD)and was not significantly different(p=0.8), nor was it at baseline(p=0.5).

Conclusion: This first prospective long term BMD and lipid follow-up study in PM EBC pts taking adjuvant letrozole beyond 5 yrs shows a decline in BMD. Until now no significant differences were observed between continuous and intermittent letrozole. An updated and detailed follow-up on more patients will be presented.
Title: The insulin-like growth factor axis and development of tamoxifen resistance in breast cancer

Yousef M Hawsawi1, James Beattie2, Reem El-Gendy3, Valerie Speirs4 and Christopher Twelves4. 1University of Leeds School of Dentistry, Leeds, West Yorkshire, United Kingdom; 2Leeds Institute of Cancer and Pathology, Leeds, West Yorkshire, United Kingdom; 3BioMedical Health Research Centre, Leeds, West Yorkshire, United Kingdom and 4King Faisal Specialist Hospital and Research Centre, Jeddah, Western, Saudi Arabia.

Body: Background
Insulin-like growth factors (IGF). IGFs are potent mitogens for breast epithelial cells that modulate the action of AKT, which has been reported to be associated with tamoxifen resistance. To date, however, anti-IGF strategies have proved disappointing in clinical trials We have investigated whether the IGFBP family of proteins, which modulate the activity of IGF, may play a role in tamoxifen resistance, opening up the route for alternative anti-IGF based therapies.

Methodology
We investigated the expression of IGF axis genes in parental and tamoxifen-resistant (TamR) MCF-7 cells using qRT-PCR. Gene and protein expression was confirmed using ELISA, Western, and ligand blotting. shRNA transfection was used to silence candidate IGF axis genes in both cell lines. Cell sensitivity 4-hydroxytamoxifen (4-HT) was investigated by WST-1 cell proliferation assay.

Results
IGF-IR, IGF-2R, IGFBP-2, -4 and -5 genes had the highest expression levels. IGFBP-5 was down-regulated 7-fold while IGFBP-2 was up-regulated by 2-fold in TamR v wt cells. Changes in IGFBP-5 and IGFBP-2 gene expression were mirrored in protein levels measured in conditioned media by ELISA, Western and Ligand blot. Importantly knock down of IGFBP-2 in TamR cells restored sensitivity to 4-HT suggesting a causal role for IGFBP-2 in the acquisition of tamoxifen resistance.

Conclusion
IGFBP-5 and IGFBP-2 are reciprocally regulated on the acquisition of tamoxifen resistance by MCF-7 cells. Preliminary studies suggest that IGFBP-2 may play a role in the development of tamoxifen resistance in vitro.
Factors associated with adherence to adjuvant endocrine therapy in patients with hormone receptor positive breast cancer

Jongjin Kim¹, Wonshik Han¹, Hyeong-Gon Moon¹, Min Kyoong Kim¹, Eunshin Lee¹, Tae-Kyung Yoo¹, Han-Byoel Lee¹, Young Joon Kang¹, Yun-Gyoung Kim¹, Tae Ryung Kim² and Dong Young Noh¹. ¹Seoul National University College of Medicine, Seoul, Korea and ²Gachon University Gil Hospital, Incheon, Korea.

Background/Purpose
Adjuvant endocrine therapy in patients with hormone receptor positive breast cancer reduces recurrence and mortality, but many patients are non-adherent to anti-hormonal medication. In order to increase the adherence, it is important to know about factors associated with adherence. So we investigated factors associated with adherence to anti-hormonal medication using variable questionnaires.

Methods
We carried out a cross-sectional survey of a sample of women who underwent surgery due to breast cancer in the Seoul National University Hospital Breast Care Center from 2007 to 2011 and treated with anti-hormonal medication. Questionnaires were sent to 1,000 patients. The questionnaire booklet included the Medication Adherence Report Scale-5(MARS-5), Women's Health Questionnaire(WHQ), Beliefs about Medicine Questionnaire(BMQ), Satisfaction with Information about Medicines Scale(SIMS). And to identify patient's clinical characteristics, we reviewed electronic medical records, retrospectively.

Result
The response rate of questionnaire was 40.8%(408/1000). Of the answered patients, 263 patients were treated with tamoxifen and 145 patients were treated with aromatase inhibitors(AIs). 197 of 408 answered patients(48.3%) were classified as non-adherence. The rate of non-adherence was 132/263(50.1%) and 65/145(44.8%) in patients treated with tamoxifen and AIs. Of the all answered patients, non-adherent patients had more depressed mood (p<0.001). Non-adherent patients scored lower on positive beliefs as measured on BMQ-necessity (OR = 0.65, 95% CI 0.51 to 0.82) and higher on negative beliefs as measured on BMQ-overuse (OR=1.81, 95% CI 1.29 to 2.54). Non-adherent patients also scored lower on satisfaction with information about action and usage of anti-hormonal treatment as measured on SIMS-action and usage (OR = 0.47, 95% CI 0.38 to 0.65). Of the patients treated with tamoxifen, non-adherent patients had more depressed mood (p=0.003), scored higher on BMQ-overuse (OR=1.97, 95% CI 1.22 to 3.20) and scored lower on SIMS-action and usage (OR = 0.33, 95% CI 0.22 to 0.50). Of the patients treated with AIs, non-adherent patients had more depressed mood (p=0.014), scored lower on BMQ-necessity (OR=0.52, 95% CI 0.36 to 0.75).

Conclusion
This study showed associations between depressive mood of breast cancer patients treated with anti-hormonal therapy and adherence. And beliefs and satisfaction with information about medication also associated with adherence. To improve adherence, we should evaluate and correct patient's mood. And we should provide proper information about medications.
**Title**: Retinoic acid sensitizes triple-negative breast cancer cells to tamoxifen treatment

Krysta M Coyle, Cheryl A Dean, Diana B Jo, Margaret Thomas, Mohammad Sultan and Paola Marcato. Dalhousie University, Halifax, NS, Canada.

**Body**: Tamoxifen, an estrogen receptor (ER) antagonist, is often used as an adjuvant endocrine therapy in the successful treatment of ER+ breast tumors. Tumors that lack ER, progesterone receptor (PR) and HER2 expression (i.e. triple-negative breast cancers) cannot be treated with adjuvant endocrine therapies, like tamoxifen, and are often more aggressive. Inducing ER expression is a potential strategy for sensitization of triple-negative breast cancers to adjuvant endocrine therapies. Given recent evidence suggesting cross-talk between the retinoic acid (RA) and estrogen signaling pathways, we investigated if RA induces expression of ER in triple-negative breast cancer cells. We hypothesize that this would lead to sensitization of the cells to tamoxifen treatment. Quantitative PCR of mRNA isolated from triple-negative MDA-MB-231 cells treated with RA and estradiol had increased ER transcript levels. Furthermore, treatment with estradiol and RA synergistically induced increased expression of RA-inducible genes. In cell proliferation studies, neither RA nor estradiol treatment alone significantly altered the growth of MDA-MB-231 cells; however, when treated with both estradiol and RA together, the growth of the cells increased significantly. This suggests that the RA-mediated increase in ER expression sensitizes MDA-MB-231 cells to estradiol-induced cell growth. Next, we investigated whether the increased ER expression sensitized MDA-MB-231 cells to tamoxifen treatment. Tamoxifen did not decrease the growth of MDA-MB-231 cells; however, when applied in combination with both estradiol and RA, tamoxifen significantly reduced MDA-MB-231 proliferation. Furthermore, tamoxifen treatment reduced the synergistic effects of estradiol/RA on RA-inducible gene expression. Together, these results suggest that the use of RA in combination with tamoxifen warrants further investigation as a potential treatment for triple-negative breast cancers. The success of the combination treatment of tamoxifen and RA in the reduction of triple-negative breast cancer cell tumor xenografts will provide further justification for this strategy in the treatment of triple-negative breast cancers.

Title: Intermittent dosing of aromatase inhibitors (AI) to improve tolerance in post-menopausal women

Vincent Launay-Vacher¹, Rémy Salmon² and Jean-Baptiste Rey³. ¹Service ICAR â–“ Pitié-Salpêtrière University Hospital, Paris, France; ²Hôpital des Peupliers, Paris, France and ³Clinical Pharmacy â–“ Institut Jean Godinot, Reims, France.

Body: Clinical rationale: A significant proportion of post-menopausal, patients treated with AI reports side-effects, especially bone pain. In such patients, the difficulties to treat pain and to clearly identify its causes may lead to treatment discontinuation. Individual cases reported an improvement in AI tolerance when dosage is reduced. The aim of this work was thus to analyse pharmacological data in order to validate this concept ie. ensuring that intermittent dosing would not result in a possibly deleterious under-dosing of AI.

Pharmacological rationale: Ageing is associated with physiological modifications that may impair drug pharmacokinetics (PKs). The elimination can be altered, with decreased drug clearance (CL), resulting in an increased exposure to the drug, reflected by increased AUCs. Drugs benefit-risk balance can thus be modified. The major sources of PKs alterations in the elderly are hepatic and/or renal impairments (HI/RI).

It has been shown that AI PKs are altered in the elderly and/or in case of HI or RI. Exemestane AUC is increased 3-fold in the elderly and in case of RI [1,2]. Letrozole AUC can double in case of HI [3] and a 42%-increase has been reported in the elderly [4]. The renal CL of anastrozole is reduced by 50% in RI, resulting in a 10% decrease in total body CL. In HI, total body CL is 30% lower as compared to normal [5].

These data demonstrate that elderly patients may be overexposed to AI when treated with the usual dosage, resulting in safety issues occurring in some patients. As a result, a dosage adjustment approach could help prevent over-exposure and reduce side-effects incidence/severity.

Proof-of-Concept studies: The reported increases in AI exposure being around 50%, an intermittent dosing schedule of 1 administration every other day could result in a similar drug exposure as compared to the usual daily schedule. AI elimination half-lives in the absence of any alteration also are consistent with this dosing schedule (24, 48, and 50 hours for exemestane, letrozole, and anastrozole, respectively). In order not to impair plasma concentrations, such a schedule is preferably suggested as compared to a half-dose daily schedule. Prospective studies are needed, in which the PKs, efficacy, and safety of this intermittent dosing schedule should be conducted.

Efficacy of adjuvant tamoxifen in hormone receptor-positive premenopausal breast cancer patients according to the body mass index

Kadri Altundag¹, Mehmet AN Sendur², Sercan Aksoy¹, Taner Babacan¹ and Yavuz Ozisik². ¹Hacettepe University Cancer Institute, Ankara, Turkey and ²Yidirim University, Ankara, Turkey.

**Body:** Introduction: Obesity is an independent risk factor for the development of breast cancer and has been associated with poor breast cancer outcomes. But, this association usually depend on hormone-receptor positivity and ovarian activity. Obesity was confirmed as an adverse prognostic factor in patients treated with aromatase inhibitors, but the adverse effects in patients treated with tamoxifen was not known exactly. Thus, we aimed to examine the efficacy of adjuvant tamoxifen in hormone receptor-positive premenopausal breast cancer patients according to the body mass index (BMI).

**Material-Methods:** Newly diagnosed hormone receptor-positive breast cancer patients who were premenopausal and non-metastatic were enrolled to the study. Patients with BMI ranging between 18.5 and 24.9 kg/m² as normal weight patients (Arm A, n = 408), and patients with a BMI ranging ≥ 25 kg/m² were overweight and obese patients (Arm B, n = 418).

**Results:** The median follow-up time for this analysis was 36 (6-327) months. The median age was 39.5 (22-57) and 43 (20-56) in Arm A and Arm B, respectively (P<0.0001). The mean BMI was 22.1 ± 1.8 kg/m² and 29.2 ± 3.3 kg/m² of Arm A and Arm B, respectively (P = <0.001). In both normal weight and overweight patients, the other baseline clinico-pathologic properties and the treatment history with radiotherapy and chemotherapy were similar and not statistically significant. In overweight and obese patients the history of diabetes mellitus and hypertension was significantly higher compared to normal weight patients. In patients with normal weight patients DFS rate was 88.5% and 78.2% whereas in overweight and obese patients DFS rate was 87.2% and 70.9% in the third and fifth years respectively (Figure 1) (P = 0.43). In patients with normal weight patients OS rate was 98.5% and 93.2% whereas in overweight and obese patients OS rate was 94.6% and 87.4% in the third and fifth years respectively (Figure 2) (P = 0.02).

**Conclusion:** Our study showed that BMI have no worse effect on recurrence risk in patients treated with tamoxifen in hormone-receptor positive premenopausal breast cancer. Poor survival outcome was observed in overweight and obese patients can be due to dose limitations of chemotherapeutic agents and higher rate of comorbid diseases.
Title: Phase I study of ARN-810, a novel and potent oral selective estrogen receptor degrader, in postmenopausal women with metastatic estrogen receptor positive (ER+), HER2- breast cancer

Aditya Bardia¹, Maura N Dickler², Ingrid A Mayer³, Eric P Winer⁴, Umar Mahmood¹, Gary Ulaner¹, H Charles Manning³, Peter Rix⁵, Jeffrey H Hager³, Debashish Roychowdhury³, Edna Chow Maneval³, Carlos L Arteaga² and Jose Baselga². ¹Massachusetts General Hospital Cancer Center, Boston, MA; ²Memorial Sloan Kettering Cancer Center, New York, NY; ³Vanderbilt-Ingram Cancer Center, Nashville, TN; ⁴Dana-Farber Cancer Institute, Boston, MA and ⁵Seragon Pharmaceuticals, San Diego, CA.

Body: Background: Evidence that ER can signal in both ligand-dependent and independent manner in endocrine resistant breast cancer (BC) provides rationale for therapies that are not only functional antagonists of ER but also reduce ER levels, thus targeting both modes of signaling. Furthermore, mutations in ESR1 affecting the ligand-binding domain (LBD) that drive ER-dependent transcription and proliferation in the absence of estrogen suggest that LBD-mutant forms are involved in mediating clinical resistance and next generation ER modulators with robust activity in both wild type and mutant ER tumors are needed. ARN-810 is a novel, orally bioavailable, ER antagonist that induces proteasomal ER degradation in BC cell lines at picomolar concentrations and tumor regression in tamoxifen-sensitive and resistant BC xenograft models.

Methods: ARN-810 was tested using standard 3+3 dose escalation to assess safety, PK, and Recommended Phase 2 Dose (RP2D). Key eligibility criteria included ER+ (HER2-) metastatic BC progressing ≥ 6 months (m) on endocrine therapy and ≤ 2 prior chemotherapies. Pre- and on-study tumor biopsies were obtained when feasible. Pharmacodynamics was assessed by functional imaging with [¹⁸F]-fluoroestradiol (FES)-PET, tumor-based ER/PR/Ki67 IHC, and ER target gene expression. Plasma PK was assessed following a single dose and at steady-state. Anti-tumor activity was assessed by clinical benefit rate (CBR) [complete response, partial response, or stable disease ≥ 6m] and progression-free survival (PFS).

Results: From April 2013 to June 2014, 32 patients (pts) (median age 61 (range 43 – 75); median number of prior therapies = 3 (range 1 – 7); visceral metastases 54%) were enrolled at 5 doses (100, 200, 400, 600, 800 mg) and 2 different regimens (once [QD] and twice daily) given orally with and without fasting. Increases in ARN-810 exposure were dose-dependent with no apparent food effect. At 4 weeks of treatment, complete reduction in FES uptake consistent with full receptor saturation and/or degradation was seen in 95% pts (21/22 scanned to date), including 2 pts with ESR1 mutations, suggesting ARN-810 exhibits greater ER occupancy than that recently reported for fulvestrant 500 mg (van Krutchen et al, ASCO 2014). Evidence of reduced ER levels and Ki67 staining was observed on treatment. To date, 19 pts (59.4%) remain on study with a preliminary CBR of 41%. RP2D, PFS and gene expression results will be provided at time of meeting. The most common adverse events were grades 1/2 nausea, diarrhea, fatigue, and abdominal pain. There was 1 dose limiting toxicity (grade 3 diarrhea) at 800 mg QD which led to expansion of that cohort, while in parallel, evaluation of the other dose regimens continues. No patients have discontinued the study due to toxicity.

Conclusions: ARN-810 appears to be safe and tolerable, with predictable PK, promising anti-tumor activity, and pharmacodynamic evidence of target engagement, ER degradation and reduced tumor proliferation in heavily pre-treated metastatic ER+ BC. In Phase II, ARN-810 will be studied in patients previously treated with aromatase inhibitors and fulvestrant, including those with ESR1 mutations.
**Title:** Visceral metastases from hormone receptor positive breast cancer are as sensitive to endocrine therapy as non-visceral metastases

John FR Robertson¹, Robert Paridaens², Jan Bogaerts³, Yuri Rukazenkov⁴, Christine Campbell⁵ and Ian Bradbury⁶. ¹University of Nottingham, Derby, Derbyshire, United Kingdom; ²Universitair Ziekenhuis Gasthuisberg, Leuven, Belgium; ³European Organisation for Research and Treatment of Cancer, Brussels, Belgium; ⁴AstraZeneca Pharmaceuticals, Macclesfield, United Kingdom; ⁵Frontier-Science, Grampian View, Kincraig, United Kingdom and ⁶Frontier-Science, Grampian View, Kincraig, United Kingdom.

**Body:**

**Background:** There remains a perception among many clinicians that visceral metastases (VMs) from hormone receptor positive (HR) breast cancer (BC) respond less well to endocrine therapy (ET) than non-VMs and so should receive chemotherapy as first line treatment.

**Patients & Methods:**

Four phase 3 randomised controlled trials (RCTs) of first line ET, all with tamoxifen (TAM) as their control arm) have been reviewed – Exemestane (Exe), fulvestrant 250mg (F250) and two with anastrozole (Ana); the latter, were study 27 in the Rest of the World (ROW) & study 30 in North America (NA). All reported objective response (OR), clinical benefit (CB), time to progression (TTP) / progression free survival (PFS); all have been published (1-5). Only HR positive tumors were included in this review. Data have been analysed both for Tam control arms alone and also for the four different endocrine agents combined.

**Results:**

CB & OR for TAM alone in each study individually and then combined are shown in the Table. The OR and CB rates were similar for non-VMs versus VMs in all studies except study 30 (NA) where CB rates were 59% for non-VM and 33% for VM (Test for heterogeneity of CB rates was p=0.047). For the four studies combined, the CB rates for non-VM versus VMs were 64% and 57% respectively (p=0.06) while the OR rates were 34% versus 30% respectively (p= 0.28).

When all endocrine agents were combined the OR rate between non-VMs and VMs was significantly different (p = 0.038) as was the CB rate (p = 0.0015). Rates of CB and OR in study 30 (NA) again appear different between non-VMs and VMs (data not shown).

The Median Duration of CB on Tam appear similar between non-VMs versus VMs, both for each study individually and when combined (see Table); when combined the Medians were 420 versus 418 days respectively with a Hazard Ratio (HR)=0.952 (0.748-1.211) (p=0.69). When all endocrine therapies for the combined four studies were assessed the HR for DoCB between non-VMs and VMs was 0.922 (0.779-1.093) (p=0.35).

For the TTP the HR of non-VMs versus VMs on Tam alone was 0.851 (0.715-1.011) (p=0.07) and for all endocrine therapies the HR was 0.821 (0.727-0.926) (p=0.001).

**Conclusions:**

HR+VMs which achieve clinical benefit on ET remain controlled for as long as non-VMs as shown by the DoCB results for both Tam and all endocrine therapies combined.

There was no significant difference in OR rates between VMs and non-VMs with Tamoxifen. There was when all endocrine agents were combined and the difference appears to be primarily due to one study (30 â– NA). There is no confirmed explanation for these differences.

TTP differences appear to be due primarily to the difference in initial CB rates in study 30 (see Table).

HR+ VMs have hormone sensitivity similar to non-visceral mets – they respond as well and for as long as non-VMs. In the absence of visceral crisis (ie immediately life-threatening disease) ET would appear to be the treatment of choice for VMs in the same way as it is for non-VMs.

Title: Association of PIK3CA mutation with clinical response to specific endocrine therapies in metastatic hormone receptor positive (HR+) breast cancer

Douglas S Micalizzi¹, Dejan Juric¹, Andrzej Niemierko¹, Kerry L Reynolds¹, Darrell Borger¹, Sadhna R Vora¹, Steven J Isakoff¹, Beverly Moy¹, Leif W Ellisen¹ and Aditya Bardia¹. ¹Massachusetts General Hospital, Boston, MA.

Body: Background: Phosphatidylinositol 3-kinase (PI3K) gene (PIK3CA) mutations are the most common somatic mutations in breast cancer. Preclinical models suggest that activating mutations in PIK3CA may mediate resistance to endocrine therapy in breast cancer, and multiple clinical trials testing combinations of endocrine therapy with PI3K inhibitors are ongoing. However, the role of PIK3CA in modulating the clinical response to endocrine therapies is less clear, with some studies suggesting that PIK3CA mutations are associated with improved prognosis in HR+ breast cancer. The primary objective of this study was to evaluate the association of PIK3CA mutation with clinical response to endocrine therapies in metastatic HR+ breast cancer.

Methods: We identified patients with metastatic HR+ /HER2 negative breast cancer, including ER+/PR+ (estrogen receptor/progesterone receptor) and ER+/PR-, to determine the time to progression (TTP) on first-line endocrine therapy for metastatic disease. PIK3CA mutations, including 8 common hotspot mutations, were assessed by a robust, high-throughput tumor genotyping assay (Snapshot), developed at our institution, using DNA derived from formalin-fixed, paraffin-embedded (FFPE) tissue. Actuarial analysis of TTP was performed using Cox proportional hazard method to compute Hazard Ratio (HR) and 95% Confidence Intervals (CI).

Results: Between 2009 and 2012, we identified 188 patients with HR+ metastatic breast cancer who had tumor genotyping performed. PIK3CA mutations were identified in 32.2% of tumors, including mutations in both helical (exon 9) and kinase (exon 20) domains (60% and 40%, respectively). The PIK3CA mutant and wild type patients had a similar median age at diagnosis of metastatic disease (55.8 and 56.7 years; p=0.2), ER+/PR+ tumors (75.0% vs 76.4%; p=0.8), and median TTP (8.2 versus 11.4 months; p=0.6). After adjusting for age at diagnosis and ER+/PR+ versus ER+/PR-, the TTP on first-line endocrine therapy did not vary among patients with PIK3CA mutations versus wild type (HR: 0.94; 95% CI:0.62-1.43; p=0.8), but did vary by type of endocrine therapy. Patients with PIK3CA mutations, as compared to wild type patients, had shorter TTP with fulvestrant (HR: 3.6; 95% CI:1.2-11.0; p=0.03), but not with aromatase inhibitors (AIs) (HR: 0.70; 95% CI:0.44-1.1; p=0.1), suggesting that mutant PIK3CA may specifically modulate the response to fulvestrant therapy. We did not observe any difference in TTP for exon 9 versus 20 PIK3CA mutations, though numbers were small resulting in limited statistical power.

Conclusion: Among patients with metastatic HR+ breast cancer in this study, PIK3CA mutations are associated with decreased time to progression with fulvestrant, but not with AIs, suggesting that these mutations may mediate resistance to specific endocrine therapies. Further studies are needed to confirm these findings and provide mechanistic insights to help guide optimal selection of endocrine therapy and combination with PI3K directed therapy in metastatic HR+ breast cancer.
Title: Enobosarm for the treatment of metastatic, estrogen and androgen receptor positive, breast cancer. Final results of the primary endpoint and current progression free survival

Beth Overmoyer¹, Pedro Sanz-Altimira², Ann H Partridge¹, Martine Extermann³, Jane Liu⁴, Eric Winer¹, Nancy Lin¹, Michael Hassett¹, Leroy Parker¹, Ryan Taylor⁵, Michael Hancock⁵, Susan Small⁶ and Mary Ann Johnston⁵. ¹Dana-Farber Cancer Institute, Inflammatory Breast Cancer Program, Boston, MA; ²Commonwealth Hematology-Oncology, Quincy, MA; ³Moffitt Cancer Center, Tampa, FL; ⁴Illinois Cancer Center, Peoria, IL and ⁵GTx, Inc, Memphis, TN.

Background: Historically, androgens have been utilized for the treatment of breast cancer (BC) as the androgen receptor (AR) is the most highly expressed steroid receptor in BC (75-95% of estrogen receptor positive (ER+) and 50% of ER negative). Reports of the use of androgens in metastatic BC (MBC) indicate that women progressing on tamoxifen have the ability to respond to synthetic androgens with overall response rates in the range of 20-60%; however, these steroidal androgens also exhibit virilizing side effects, thus limiting clinical use. A non-steroidal, tissue-selective, AR modulator (SARM), such as enobosarm, offers a targeted approach of AR activation without virilization or estrogenic effects.

Methods: This is a phase II proof of concept study examining the efficacy and safety of once daily enobosarm 9 mg in post-menopausal women with ER+ MBC who had responded to adjuvant and/or salvage endocrine therapy. Therapy is continued until patients display evidence of disease progression. The proportion of AR+ patients with clinical benefit response (CBR) at 6 months is the primary endpoint; defined as patients with a complete response (CR), partial response (PR), or stable disease (SD) as detailed in modified RECIST 1.1. AR status of metastatic disease will be correlated with CBR. Serum prostate specific antigen (PSA) will be assessed as a biomarker of AR activation by drug. Secondary endpoint is progression free survival (PFS).

Results: Patient demographics: mean age 63.7 years, mean time from diagnosis 11.0 years, 72.7% prior chemotherapy, 89% (17/19) AR+. After a median follow-up of 81 days (range 7-304 days), preliminary results of 22 patients: 9 SD as best response, median duration 212 days. Current disposition of patients: 15 PD after a median 80 days (range 15-304 days), 4 SD (1 on treatment for < 6 months), and 3 early discontinuations (days 7, 28, 255). Five patients have died due to PD off study. Among the 17 evaluable patients, 6 reached the primary endpoint (35.3%; 95% CI=16.6% to 59.4%) with increased PSA, thereby exceeding the pre-defined statistical threshold requiring that at least 3 of 14 patients with an AR+ metastatic lesion demonstrate clinical benefit. CR or PR has not been observed. Current six month Kaplan-Meier estimate of PFS is 43.8% (95% confidence interval=19.5% to 68.1%). Enobosarm is well-tolerated with common grade 1/2 toxicities of nausea (8%), menopausal symptoms (13%), pain (25%), fatigue (10%), weight change (4%); 5 (4%) grade 3 toxicities (3 unrelated to drug, 1 bone pain, 1 fatigue), and no grade 4 or higher toxicities reported. Final results of the study will be available in the fourth quarter of 2014.

Conclusions: Enobosarm demonstrates promise as a novel endocrine agent for AR+ MBC. The primary endpoint has been achieved, with 6/17 AR+ patients meeting statistical threshold for success (35% CBR at 6 months). Serum PSA appears to be a surrogate marker for AR activity associated with enobosarm administration. Based upon these favorable preliminary findings, a larger phase II study is anticipated.
Title: Role of pharmacogenetics in metastatic breast cancer (MBC) patients treated with exemestane as first-line hormonal therapy. An Italian multicentre study

Sara Gagno1, Mauro Mansutti2, Daniele Rossini3, Diana Crivellari4, Chiara Zanussi5, Silvana Saracchini6, Donata Sartori7 and Giampietro Gasparini8. 1Doctoral School in Pharmacological Science, University of Padua, Italy; 2S. Maria della Misericordia; 3A.C.O. San Filippo Neri, Rome; 4CRO National, Cancer Institute, Aviano (PN); 5Post Graduate School Clinical Pharmacology, University of Milan, Milan, Italy; 6A.O. Santa Maria degli Angeli, SC Oncology, Pordenone (PN) and 7Azienda ULSS n.13, U.O.C. Oncologia ed Ematologia Oncologica Mirano- Dolo- Noale (VE).

Body: Background: In a subset of MBC patients exemestane is not effective. Single Nucleotide Polymorphisms (SNPs) of genes involved in estrogen availability, in pharmacokinetics (PK) and pharmacodynamics (PD) of exemestane could be responsible for responsiveness. CYP19A1_Ex11+410A/C – rs4646 was found to correlate with improved overall survival in patients treated with letrozole(1) and anastrozole (2).

Methods: This multicentre study enrolled 423 patients with diagnosis of MBC or locally advanced-ER-positive breast cancer treated with exemestane as first-line hormonal therapy (prior adjuvant therapy and chemotherapy for metastatic setting were admitted). Objective of the study was to prospectively assess the predictive role of polymorphisms in aromatase gene, in particular CYP19A1_Ex11+410A/C – rs4646, and in genes involved in the PK and PD of exemestane on drug's activity (Response Rate - RR, time to progression - TTP). The correlation between SNPs and RR was assessed by the Fisher's exact test two-way. The CYP19A1_Ex11+410A/C – rs4646, CYP1B1*3_4326G/C (rs1056836) and other not pre-planned polymorphisms were analyzed. Moreover, in a subset of patients, PK and PD analysis were also performed.

Results: At present time we report the preliminary results on 196 patients. Among these patients, CYP19A1_Ex11+410A/C – rs4646 SNP shows no significant association with RR, whereas in patients carrying at least one variant allele of CYP1B1*3_4326G/C (rs1056836) polymorphism, a statistically significant association with a better response to exemestane was found (dominant model: OR =.436, 95% CI =.21 to .89, p = .029; Clinical benefit, dominant model: OR =.362, 95% CI =.17-0.75, p = .007, Fisher's Exact Test in accordance with the two-way). The same SNP seems, in the pharmacodynamic analysis, to be associated with the level of estrogen suppression (p =.0508 according to the Kruskal-Wallis ANOVA) and associated to better RR (p =.0287; Clinical B benefit: p =.0209 according to the Wilcoxon-Mann-Whitney test), providing a basis for phenotypic association. The overall results on the entire cohort of patients enrolled are under evaluation as well as the data concerning TTP, toxicity and the correlation with PR, HER2 and Ki67 tumor tissue expression.

Conclusions: A predictive role of the CYP1B1*3_4326G/C (rs1056836) polymorphism for RR to exemestane as first-line therapy has been found. Our study suggests that a simple genetic evaluation from peripheral blood, performed prior to therapy, may allow the identification of the patients who are more likely to be responsive to exemestane.
**Title:** Impact of visceral metastases on treatment patterns for hormone-receptor-positive (HR+)/human epidermal growth factor receptor-2-negative (HER2-) metastatic breast cancer (mBC)

James Signorovitch¹, Jenny Wang², Ruo-Ding Tan¹, Darren Thomason¹, Andrew Kageleiry¹ and Elyse Swallow¹. ¹Analysis Group, Inc, Boston, MA and ²Novartis Pharmaceuticals Corporation, East Hanover, NJ.

**Body:** Introduction:
Guidelines recommend reserving chemotherapy (CT) for HR+/HER2- mBC until either endocrine-based therapy (ET) is no longer effective or for patients with visceral crisis or need for rapid tumor control. The extent to which visceral metastases (VM), regardless of whether they are contributing to visceral crisis, impact real-world treatment patterns in mBC is not well understood. This retrospective analysis characterizes treatment patterns with ET and CT among HR+/HER2- mBC patients stratified by presence of VM.

Methods:
Postmenopausal women (age ≥50 years) diagnosed with HR+/HER2- mBC were identified from the MarketScan® database (2002Q3-2012Q2). Patients who initiated ET without CT for mBC were followed until transition to CT, discontinuation of ET (>90 days without evidence of ET), or end of data or insurance eligibility. Upon initiation of each line of therapy, patient characteristics including age, number of metastatic sites, and presence of VM were compared between those receiving ET and those receiving CT. The number of lines of ET received before CT, and the total duration of ET were described for patients with and without VM.

Results:
Of the 19,120 patients who initiated treatment for mBC, 5,418 received 2nd-line treatment and 1,471 received 3rd-line treatment. In each of these 3 lines, the corresponding numbers of patients receiving CT were 7,575 (40%), 2,397 (44%) and 650 (44%). Among the patients who received CT in each line, the majority did so without evidence of VM: 5,821 (77%), 1,511 (63%) and 435 (67%), in the 1st, 2nd and 3rd lines, respectively. Within each line, the average patient receiving CT was approximately 3 to 5 years younger and had 0.02-0.29 more metastatic sites, compared with the average patient receiving ET. Among the 11,545 patients who initiated 1st-line ET, 9,315 (81%) did not have evidence of VM. Patients with versus without VM upon initiation of 1st-line ET received similar average numbers of lines of ET (1.32 versus 1.37 lines). However, the median time prior to transition to CT, discontinuation of ET, or loss to follow-up was shorter for patients with VM compared to those without VM (5 months versus 10 months). In addition, patients with VM appeared to have shorter durations of ET at each line compared with patients without VM (Table).

Conclusions:
Although the present analysis could not distinguish visceral crisis from the broader group of patients with visceral metastases, it is notable that a large majority of patients receiving CT did so without evidence of VM. This indicates an unmet need during the study period (2002-2012) for effective disease control among patients without VM for whom CT was not a preferred option.

A phase III study of fulvestrant 500 mg versus 250 mg in postmenopausal Chinese women with advanced breast cancer and disease progression following failure on prior antiestrogen or aromatase inhibitor therapy: Supporting superior clinical benefit for the 500 mg dose

Zefei Jiang¹, Qingyuan Zhang², Zhimin Shao³, Kunwei Shen⁴, Li Li⁵, Jifeng Feng⁶, Zhongseng Tong⁷, Kangsheng Gu⁸, Xiaojia Wang⁹, Binghe Xu¹⁰, Guofang Sun¹¹, Huifang Chen¹¹ and Yuri Rukazenkov¹². ¹Beijing 307 Hospital, Beijing, China; ²Tumour Hospital of Harbin Medical University, Harbin, Heilongjiang, China; ³Tumor Hospital of Fudan University, Shanghai, China; ⁴Shanghai Ruijin Hospital, Shanghai, China; ⁵First Affiliated Hospital of Dalian Medical University, Dalian, Liaoning, China; ⁶Jiangsu Cancer Hospital, Nanjing, Jiangsu, China; ⁷Tianjin Cancer Hospital, Tianjin, China; ⁸First Affiliated Hospital of Anhui Medical University, Hefei, Anhui, China; ⁹Zhejiang Cancer Hospital, Hangzhou, Zhejiang, China; ¹⁰Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China; ¹¹AstraZeneca China, Shanghai, China and ¹²AstraZeneca Pharmaceuticals, Macclesfield, United Kingdom.

Body: Background: In the international Phase III COmparisoN of Faslodex In Recurrent or Metastatic breast cancer (CONFIRM) study, fulvestrant 500 mg was associated with significantly longer progression-free survival (PFS) over the 250 mg dose (hazard ratio [HR] 0.80; 95% confidence interval [CI] 0.68, 0.94; p=0.006) in postmenopausal women with advanced breast cancer (ABC) following failure on prior endocrine therapy. There were no clinically meaningful differences between the treatment groups in terms of the incidence or severity of adverse events. The present study was designed to compare the efficacy and safety of fulvestrant 500 mg versus 250 mg in a Chinese population for registration purposes.

Methods: This was a Phase III randomized, double-blind study in a Chinese population (ClinicalTrials.gov: NCT01300351). Postmenopausal women with estrogen receptor positive (ER+) ABC following failure on prior endocrine (antiestrogen [AO] or aromatase inhibitor [AI]) therapy were randomized 1:1 to fulvestrant 500 mg or 250 mg. Patients (pts) were stratified by post-AO/post-AI status and enrollment of post-AI pts was capped at 45%. Primary study endpoint was PFS. Consistency with the global CONFIRM study was to be concluded if the HR for the treatment comparison of PFS was <1 (full analysis set; stratified log-rank test); the study was not powered to detect significant differences between the treatment groups. Secondary endpoints included pharmacokinetics, ORR, CBR, DoR, DoCB, safety and tolerability.

Results: 221 pts were randomized to fulvestrant 500 mg (n=111) or fulvestrant 250 mg (n=110). 121 pts were in the post-AO subgroup and 100 pts were in the post-AI subgroup. Demographic and baseline characteristics were balanced between fulvestrant 500 mg and fulvestrant 250 mg and comparable with those in the global CONFIRM study. 98% (119/121) in the post-AO subgroup and 92% (92/100) in the post-AI subgroup had adjuvant endocrine therapy, while only 12% (14/121) in the post-AO subgroup and 51% (51/100) in the post-AI subgroup used salvage endocrine therapy. At the time of the primary analysis, 152 progression events (69%) had occurred (post-AO 59% [71/121]; post-AI 81% [81/100]). Median PFS was 8.0 months (m) in the fulvestrant 500 mg group vs 4.0 m in the 250 mg group (HR 0.75; 95% CI 0.54, 1.03; p=0.078); the predefined criterion for consistency with the global CONFIRM study was met. In a predefined subgroup analysis of PFS, the HR for fulvestrant 500 mg vs 250 mg was <1 in both post-AO (median PFS 8.1 m vs 5.6 m; HR 0.86; 95% CI 0.54, 1.37) and post-AI (median PFS 5.8 m vs 2.9 m; HR 0.65; 95% CI 0.42, 1.03) subgroups. Secondary endpoints favored fulvestrant 500 mg over 250 mg, with the exception of median DoR. Safety and tolerability profiles were consistent with the known safety profile of fulvestrant.

Conclusions: Data from the present study support the superior clinical benefit of fulvestrant 500 mg vs 250 mg demonstrated in the global CONFIRM study, in postmenopausal Chinese women with ER+ ABC. Hazard ratios favoring fulvestrant 500 mg were observed in both the post-AO and post-AI settings.
Body: **Background:**
Guidelines recommend maximizing the duration of effective treatment that can be achieved without chemotherapy for HR+/HER2- mBC, with the goal of avoiding toxicity and preserving quality of life. A target of three lines of ET is suggested, with CT reserved for patients requiring rapid control of symptomatic disease or who no longer benefit from ET. This study describes treatment patterns for HR+/HER2- mBC over the past decade.

**Methods:**
Postmenopausal women (age \(\geq 50\)) with HR+/HER2- mBC were identified from the MarketScan® databases (2002Q3-2012Q2). Patients whose first treatment after mBC diagnosis included ET without CT were followed until first use of CT, discontinuation of ET (>90 days without evidence of ET), or end of data or insurance eligibility. The distribution of agents used prior to CT was assessed for up to 3 lines of therapy. Median treatment durations were calculated by agent and by line among patients who received at least 3 lines of treatment that included ET without CT.

**Results:**
Of 19,120 HR+/HER2- mBC patients, 11,545 (60%) initiated a 1st-line therapy for mBC that included ET without CT. The remaining 40% initiated with CT. Of the 11,545 patients who initiated ET, the majority received the non-steroidal aromatase inhibitors (NSAIs) anastrozole (38%) and letrozole (27%) in the 1st-line. Among these patients, 3,021 (26%) patients received 2nd-line ET without CT, with the majority receiving exemestane (20%), anastrozole (18%), letrozole (18%) or fulvestrant (18%). A total of 821 patients, comprising 7% of the patients who received 1st-line ET, received at least 3 consecutive lines of ET without CT. The majority of these patients received exemestane (20%), tamoxifen (19%) or fulvestrant (19%) in the 3rd line. Among these 821 patients, the median treatment durations were 9, 6, and 3 months in the 1st, 2nd, and 3rd lines, respectively. Median durations for each ET agent were generally lower in later versus earlier treatment lines (Table). At the time of data cutoff for this study, limited data were available for everolimus treatment (n=21).

**Conclusions:**
The large majority of patients did not receive the guideline-recommended target of 3 lines of ET. Additionally, the shorter durations of therapy observed within each subsequent line of ET suggest that there may be diminishing returns for sequential use of ET monotherapies for HR+/HER2- mBC. These findings indicate an unmet need for more effective alternatives to available ET monotherapies after the initial ET discontinuation during the study period (2002-2012).

Title: First report of clinicopathological analysis in neoadjuvant treatment phase in NEOS: A randomized study of adjuvant endocrine therapy with or without chemotherapy for postmenopausal breast cancer patients who responded to neoadjuvant letrozole

Takehiko Sakai, Hiroji Iwata, Yoshiie Hasegawa, Rikiya Nakamura, Hiromitsu Akabane, Shoichiro Ohtani, Masahiro Kashiwaba, Naruto Taira, Tatsuya Toyama, Yutaka Yamamoto, Tomomi Fujisawa, Norikazu Masuda, Takuhiro Yamaguchi, Hirofumi Mukai and Yasuo Ohashi.

Body: Background: Whether adjuvant chemotherapy is required for patients with intermediate-risk endocrine-responsive postmenopausal breast cancer remains unknown. The New primary Endocrine-therapy Origination Study (NEOS: N-SAS BC06 study: UMIN 000001090) was a randomized controlled trial to verify the necessity of adjuvant chemotherapy in node-, ER+, and HER2- postmenopausal breast cancer patients who responded to neoadjuvant endocrine therapy. The primary registration and primary treatment have finished. This report evaluated clinical responses and radiological findings in the neoadjuvant LET treatment phase of 6 months.

Methods: Patients meeting eligibility criteria received LET preoperatively in weeks 24-28 after primary enrollment. Patients evaluated as complete response (CR), partial response (PR) or stable disease (SD) by each investigators underwent secondary enrollment and will be divided at random into two arms, an arm given LET for 4.5-5 years after chemotherapy and another arm given only LET for 4.5-5 years. Patients evaluated as progressive disease during LET treatment will receive discretionary treatment. The primary endpoint was disease-free survival and secondary endpoints were overall survival, clinical response rate in neoadjuvant treatment phase, pathological response, breast-conserving surgery rate, DFS/OS in subgroups according to clinical response, safety, HRQOL, and cost-effectiveness.

Results: Between May 2008 and June 2013, 905 patients entered primary registration. We excluded 42 patients without confirmed data. The 863 included patients' characteristics at baseline are: median age: 63 years old, median Body Mass Index (BMI): 23.90, T1c: 37%, T2: 63%, and PgR+: 79%, and 74% of patients had planned breast-conserving surgery (BCS). The clinical responses were evaluated with calipers, ultrasound and MRI (or CT) at the baseline and end of treatment before surgery. Clinical response rates were 2, 48, 46 and 4% in CR, PR, SD and PD, respectively. Excluding those who could not enter secondary registration according to the protocol, 83 (56.1%) of 148 patients with planned total mastectomy were converted to BCS according to final radiological evaluations before surgery. The correlation between the tumor size on MRI (r=0.87) after neoadjuvant LET and the pathological invasive tumor size was stronger than with other modalities (r=0.68, 0.57, 0.33 by CT, US and calipers, respectively). On univariate analysis, a small tumor size (T1c rather than T2), PgR+, HER2:2+ and a high BMI at the baseline were significantly correlated with the clinical response. On multivariate analysis, PgR+ (HR: 1.13, 95%CI: 1.01-1.27, p=0.032) and a small tumor size (HR: 1.11, 95%CI: 1.03-1.17, p=0.003) were significant independent predictors of the clinical response. Conclusion: This is the first clinical report of neoadjuvant hormone therapy for early breast cancer. Neoadjuvant LET therapy improved BCS rates. MRI was useful for predicting the residual pathological invasive tumor size. PgR+ and a small tumor size at the baseline were significant independent predictors of the clinical response.
Title: Neoadjuvant letrozole and lapatinib is feasible in Asian postmenopausal women with estrogen receptor (ER) and human epidermal growth factor receptor-2 (HER-2) positive breast cancer [Neo-All-In]: First efficacy and safety report

Ji Hyun Park1, Myoung Joo Kang2, Jin-Hee Ahn1, Jeong Eun Kim1, Kyung Hae Jung1, Gyun-Yub Gong3, Hee Jin Lee3, Byung-Ho Son4, Sei-Hyun Ahn5, Hak-Hee Kim5, Hee Jung Shin6, Dae-Hyuk Moon6 and Sung-Bae Kim1. 1Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; 2Inje University Haeundae Paik Hospital, Busan, Korea; 3Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; 4Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; 5Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea and 6Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea.

Body: Purpose Neo-ALL-In (NCT 01275859) is a single center, prospective study aimed to evaluate the recruitment feasibility, efficacy and safety profiles as well as biologic features of neoadjuvant letrozole plus lapatinib in postmenopausal women with ER and HER2 positive breast cancer.

Methods Postmenopausal women with stage IIA to IIIB ER and HER-2 positive breast cancer were eligible. Patients received combination therapy of letrozole 2.5 mg orally daily plus lapatinib 1,500 mg orally daily for 18-21 weeks before surgery. Clinical responses were assessed by clinical palpation, ultrasonography (US), mammography and/or MRI. Tissue and/or blood samples were collected for analysis of biomarkers at three time points (baseline, day 15, and before surgery). Baseline Fluorine-18 Fluorodeoxyglucose (18F-FDG) and Fluorine-18 Fluoroestradiol (18F-FES) PET-CT imagings were obtained.

Results Among twenty-four patients enrolled, 22 patients underwent surgery while 1 patient is currently on neoadjuvant therapy and the other patient is waiting for surgery. Among 22 patients completed surgery, 16 patients (72.7%) completed planned neoadjuvant letrozole and lapatinib, whereas 3 patients (13.6%) prematurely terminated the treatment and proceeded to surgery due to minimal clinical response or progression. Except grade 3 liver toxicities revealed in 3 patients (13.6%), which resulted in sequential dose reduction and discontinuation, adverse events were mainly grades 1 to 2 (Skin, 83.3%; GI, 77.3%), and these were generally tolerable with excellent compliance. Overall clinical response rates including complete and partial response was 72.7% (n=16), and pathologic complete response in breast (pCR; ypT0-is) was 4.5% (n=1).

CR, complete response; PR, partial response; PD, progressive disease; US, ultrasonography

In analyses of biomarkers thus far, 81.8% of patients showed stationary expression of HER-2, 54.5% of patients showed decrease in Ki-67 expression, and 27.3% of patients showed increase in ER expression from baseline to surgery by immunohistochemistry (IHC) staining. Decreased expression of ER after surgery by IHC staining was significantly correlated with poor clinical response (p=0.004). However, no significant differences in baseline SUVmax in FDG-PET were found between responders and non-responders (8.8 VS 10.7, p=0.53).
Conclusion This chemo-free combination neoadjuvant therapy was feasible, with comparable efficacy outcomes and manageable toxicities profiles. Updated data on $^{18}$F-FES PET-CT and biomarkers will be provided.
Title: Association between ischemic cardiac events and targeting of the internal mammary nodal region with adjuvant radiation for breast cancer

Adam L Liss¹, Kent A Griffith², Reshma Jagsi¹, Jean M Moran¹, Robin B Marsh¹, Todd M Koelling³ and Lori J Pierce¹. ¹University of Michigan, Ann Arbor, MI; ²Biostatistics Unit, University of Michigan, Ann Arbor, MI and ³University of Michigan, Ann Arbor, MI.

Body: Background: Cardiac toxicity has been well documented following adjuvant breast cancer radiation therapy (RT) using outdated treatment methods. Limited information exists, however, regarding cardiac outcomes following contemporary RT fields and techniques. Inclusion of the internal mammary nodal (IMN) field for appropriately selected patients with breast cancer coincided with our department’s transition to computed-tomography (CT) based planning. The objectives of this study, therefore, were to assess the risk of ischemic cardiac events following IMN irradiation and to assess the risks following CT-based versus two-dimensional (2D) planning.

Methods: All patients treated with adjuvant RT for breast cancer and without history of additional chest RT from January 1, 1984 – December 31, 2007 in our department were assessed. CT planning for breast cancer began for select patients in 1997 and was used for all patients as of 2001. The inclusion of the IMN region was determined by review of our clinical database. Ischemic cardiac endpoints were defined as myocardial infarction, coronary artery bypass grafting procedure, angioplasty/stent placement, and/or diagnosis of coronary artery disease. A text-based and diagnosis code-based search was used to flag possible endpoints which were then confirmed by manual chart review. Hypertension (HTN), diabetes (DM), hyperlipidemia (HLD), and anthracycline use were identified by a diagnosis code-based search.

Results: We identified 2,126 patients who received adjuvant RT. Median follow-up was 9.6 years. 311 (14.6%) patients had IMNs targeted and 1,813 (85.3%) did not (data not available for 2 patients). RT to the IMNs was not associated with a higher risk of ischemic cardiac events (HR: 0.88, P = 0.731). 1,072 (50.4%) patients had CT planning, 1,003 (47.2%) had 2D planning, and no information was available for 51 (2.4%) patients. Overall, there were 56 (5.6%) ischemic events in the 2D cohort and 27 (2.5%) in the CT cohort. After truncating follow-up to 10 years to account for differential potential follow-up, there were 28 (2.8%) and 23 (2.2%) ischemic cardiac events, respectively. The table lists the association of patient and treatment characteristics and risk of ischemic cardiac events. HTN, HLD, and DM were each associated with a significantly increased risk of ischemic cardiac events.

Conclusions: After reviewing all patients treated in our department for breast cancer from 1984 – 2007, we were unable to find an association between IMN irradiation and ischemic cardiac events. CT-based planning has been shown to allow accurate targeting of the IMNs. These data suggest that even with inclusion of the IMNs, CT-based planning minimizes dose to the heart and coronary arteries thereby decreasing the risk of ischemic cardiac toxicity. These results will be followed with time.

Title: Utilization of hypofractionated radiation therapy for early stage breast cancer in women over 50 years of age

Malolan S Rajagopalan¹, Craig Lehockey¹, John C Flickinger¹, Dwight E Heron¹, Paniti Sukumvanich², Joseph L Kelley², Gretchen M Ahrendt³ and Sushil Beriwal¹. ¹University of Pittsburgh Cancer Institute, Pittsburgh, PA; ²University of Pittsburgh Cancer Institute, Pittsburgh, PA and ³University of Pittsburgh Cancer Institute, Pittsburgh, PA.

Body: Purpose: Hypofractionated whole breast irradiation (HF-WBI) following breast conserving surgery for early stage breast cancer is now recommended for women over 50 years of age by the American Society for Radiation Oncology (ASTRO). Herein, we explored the rate of HF-WBI utilization and its associated patterns of care using the National Cancer Data Base (NCDB), a comprehensive oncology outcomes database which captures 70% of all newly diagnosed cancer patients in the US.

Methods: We utilized NCDB to identify women aged ≥50 diagnosed with T1N0/T1Nx invasive breast cancer or Tis (DCIS) who underwent breast conserving surgery and adjuvant whole breast external beam radiation therapy. HF-WBI was defined when a definitive radiation dose (≥40 Gy) was delivered in ≤23 fractions. We evaluated factors associated with the use of HF-WBI through exploratory univariate and multivariable analyses.

Results: A total of 311,071 patients from 1998-2011 met inclusion criteria. The commonest HF-WBI regimen was 42.56 Gy in 16 fractions. The rate of HF-WBI utilization increased over time from 0.4% in 1998 to 16.5% in 2011 (p<0.001). HF-WBI was delivered more often for women of advancing age. In 2011, HF-WBI was delivered in 10.0%, 14.2%, 24.2% and 35.6% of women in their 50’s, 60’s, 70’s and 80+ (p<0.001). Multivariable analysis correlated significantly increased use of HF-WBI with (in order of association): later year of diagnosis, advancing age (decade), treatment in academic center, regional location in US, lower grade of disease, white race, residence in a higher income area (p<0.001), greater comorbidity score (p<0.03), presence of invasive cancer (p<0.01), right-sided disease (p<0.01), and greater distance from reporting facility (p<0.001).

Conclusions: This comprehensive patterns of care study of HF-WBI in women ≥50 years old with early stage breast cancer from a national database identified a substantial increase in the utilization of this technique with time. Advancing patient age and treatment at academic facility were also strong predictors of delivery of HF-WBI. Disparities in utilization of HF-WBI and overall employment of this technique, even in later years, remain suboptimal. Strategies to identify and break barriers to the adoption of HF-WBI should be explored.
Title: Long term outcomes in patients with phyllodes tumor of the breast: The UT MD Anderson experience

Bobbi A Porche¹, Pamela K Allen², Simona Shaitelman², B Ashleigh Guadagnolo², Wendy A Woodward², Constance Albarracin², Abenaa M Brewster², Kelly K Hunt² and Welela Tereffe². ¹UT Medical School at Houston, Houston, TX and ²MD Anderson Cancer Center, Houston, TX.

Body: Purpose: Phyllodes tumor is a relatively rare disease of the breast, and the risk factors for local versus distant failure are unclear. The goal of this study was to identify factors influencing local, distant, and cause-specific survival outcomes in patients with phyllodes tumors, and to assess the impact of local radiotherapy (RT).

Methods: We retrospectively reviewed the records of 387 patients recorded in the MD Anderson tumor registry as having "cystosarcoma phyllodes" or "phyllodes". After excluding patients with recurrent disease at presentation to the institution, concurrent invasive ductal carcinoma, absence of confirmation of phyllodes tumor, or inadequate follow up after surgery, 229 patients diagnosed from 1964-2011 were evaluable. The median tumor size was 4 cm (range, 0.7-28 cm); histology was benign in 29%, indeterminate in 7%, and malignant in 41% (23% unknown). Stromal overgrowth was present in 18% (n=40). Local therapy consisted of breast-conserving surgery (n=184) or mastectomy (n=43); 15% (n=34) also received local RT. Chemotherapy was administered in 9% (n=21). We used Kaplan-Meier analyses and Cox proportional hazards models to estimate the associations between patient/tumor characteristics and treatment on local control (LC), distant metastasis-free survival (DMFS), and cause specific survival (CSS).

Results: At a median follow-up of 76 months (range, 1-485 months), the actuarial 5-yr LC for the entire cohort was 75%; 5-yr DMFS was 78%; and 5-yr CSS was 86%. Factors influencing LC included receipt of RT (5-yr LC 97% versus 72%, p=.005) and age over 50 (85% versus 72%, p=.044). Neither malignant histology nor stromal overgrowth increased the risk of local failure. Factors influencing DMFS included malignant histology (5-yr DMFS 65% versus 91%, p=.001) and stromal overgrowth (50% versus 84%, p<.001). Factors influencing CSS included malignant histology (5-yr CSS 77% versus 100%, p=.002) and stromal overgrowth (58% versus 92%, p<.001). Patients with stromal overgrowth or malignant histology were much more likely to receive RT (p<.001 for both factors). RT improved 5-yr LC for both breast conserved and mastectomy patients, but did not improve DMFS or CSS. In multivariable models, the following associations were noted (HR=hazard ratio; CI= 95% confidence interval): LC – RT (HR 0.13, CI .03-.55); DMFS – malignant histology (HR 2.99, CI 1.41-6.34); CSS – malignant histology (HR 4.18, CI 1.43-12.24).

Conclusions: Adjuvant RT after surgery improves local control in phyllodes tumor; however, it does not improve DMFS or CSS. Stromal overgrowth and malignant histology are associated with worse DMFS and CSS, but do not impact local control. Therefore malignant histology and stromal overgrowth should not be deciding factors in the use of local RT, as escalated local therapy in patients with these tumor characteristics does not improve DMFS or CSS. Other strategies should be considered for patients with phyllodes tumor who are at high risk of distant failure, including systemic therapy.
The adoption of hypofractionated whole breast irradiation for early-stage breast cancer: A national cancer data base analysis

Elyn H Wang¹, Sarah S Mougalian², Pamela R Soulos³, Charles E Rutter⁴, Suzanne B Evans⁴, Bruce G Haffty⁵, Cary P Gross⁶ and James B Yu⁴. ¹Yale University School of Medicine, New Haven, CT; ²New Haven, CT; ³Cancer Outcomes, Public Policy, and Effectiveness Research Center at Yale, New Haven, CT; ⁴Department of Therapeutic Radiology, New Haven, CT; ⁵Rutgers Cancer Institute of New Jersey and Robert Wood Johnson Medical School, New Brunswick, NJ and ⁶Department of Internal Medicine, New Haven, CT.

Body: Purpose
Hypofractionated whole breast radiation therapy (hypofractionation) for early-stage breast cancer is a treatment innovation that is both supported by high quality randomized trial evidence and clinical guidelines, and is more cost effective and convenient than conventional fractionation. However, whether hypofractionation has been adopted nationally, and what factors are related to its adoption, are unknown.

Methods
We performed a retrospective study of breast cancer patients in the National Cancer Data Base from 2004-2011 who were treated with radiation therapy and met eligibility criteria for hypofractionation. We used logistic regression to identify factors associated with receipt of hypofractionation (vs. conventional fractionation).

Results
We identified 13,271 (11.7%) and 99,996 (88.3%) women with early-stage breast cancer who were treated with hypofractionation and conventional fractionation, respectively. The use of hypofractionation increased significantly, with 5.4% of patients receiving it in 2004 compared with 22.8% in 2011 (P<0.001 for trend). Patients living >50 miles from the cancer reporting facility had increased odds of receiving hypofractionation (OR 1.57 [95% CI 1.44-1.72], p<.001).

Adoption of hypofractionation was associated with treatment at an academic center (p<0.001) and living in an area with high median income (p<0.001). Hypofractionation was less likely to be used in patients with high risk disease, such as increased tumor size (p<0.001) or poorly differentiated histologic grade (p<0.001).

Adjusted odds ratios for receipt of conventional fractionation vs hypofractionation

Conclusions
The use of hypofractionation is rising and is associated with increased travel distance and treatment at an academic center. Further adoption of hypofractionation may be tempered by both clinical and non-clinical concerns.
Title: Long-term outcome of electron intraoperative boost and hypofractionated external beam radiotherapy after breast-conserving surgery in premenopausal women

Maria Cristina Leonardi¹, Anna Morra¹, Cristiana Fodor¹, Luigi Santoro¹, Samantha Dicuonzo¹, Roberta Lazzari¹, Veronica Dell'acqua¹, Elena Rondi¹, Federica Cattani¹, Floriana Pansini¹, Alberto Luini¹ and Roberto Orecchia¹². ¹European Institute of Oncology, Milan, Italy and ²University of Milan, Milan, Italy.

Body: Purpose: To report long-term clinical results on breast cancer patients treated with an electron intraoperative boost followed by hypofractionated external beam radiotherapy (HEBRT) to the whole breast inside a clinical protocol.

Materials and Methods: Between June 2004 and December 2008, 357 premenopausal women with a diagnosis of early-stage breast cancer were given breast conservative surgery (quadrantectomy and sentinel node biopsy +/- axillary dissection). During surgery, an electron intraoperative boost of 12 Gy was administered to the tumour bed. Within 4 weeks after having received the IORT boost, the whole breast was irradiated with hypofractionated scheme. HEBRT consisted of 13 daily fractions of 2.85 Gy up to a total dose of 37.05 Gy, with 3-D conformal technique. Median age was 42 years (24-48). Pathologic stages were distributed as follow: stage 0 4 (1.1%), I 192 (53.8%), stage IIA 108 (30.3%), stage IIB 28 (7.8%), stage IIIA 18 (5%), stage IIIC 6 (1.7%), CR 1 (0.3%).

The biomolecular classification included 33 triple negative patients.

All patients but one received adjuvant systemic treatment, according to tumor features. Chemotherapy +/- endocrinotherapy was offered to 149 patients, while endocrinotherapy alone was given to 197 patients. In all cases, adjuvant chemotherapy commenced after the completion of HEBRT. Follow-up was carried out on a regular basis by breast surgeons and radiation oncologists.

Results: Median follow-up was 83.1 months (range 9.1-118.9). 340 patients were alive and 317 were free of any disease (89%). Three patients (0.8%) had nodal regional recurrence, 12 patients (3.4%) had local recurrence, 26 patients (7.3%) had distant metastasis. 13 patients (3.6%) developed contralateral breast cancer. 12 patients (3.4%) had a new primary tumor in other site. 15 patients (4.2%) died due to progression of disease, while two died of other causes not related to the breast cancer.

Conclusions: This shortened scheme including intraoperative anticipated boost and hypofractionated whole breast radiotherapy showed a good local control at 5 years follow-up. The patients' compliance is very high and in patients who are in need of chemotherapy, the time gap between surgery and radiotherapy treatment is avoided. As follow-up length increases, a greater number of patients will achieve the minimum 5-year period to receive the first long-term evaluation and the strength of the results on efficacy is bound to increase.
Title: Lobular histology and partial breast irradiation: To what extent is it a cautionary parameter?

Maria Cristina Leonardi¹, Patrick Maisonneuve¹, Anna Morra¹, Nicole Rotmensz¹, Samantha Dicuonzo¹, Roberta Lazzari¹, Veronica Dell'acqua¹, Federica Cattani¹, Mauro Mastropasqua¹, Alberto Luini¹ and Roberto Orecchia¹,². ¹European Institute of Oncology, Milan, Italy and ²University of Milan, Milan, Italy.

Body: Aim: The high likelihood of multicentricity and multifocality linked to lobular histology (ILC) has called into question the partial breast irradiation. Patients with ILC are categorized in the cautionary group according to ASTRO guidelines. We looked into the population treated with intraoperative radiotherapy with electrons (ELIOT) as full dose to investigate the impact of lobular compared to ductal histology (IDC) in terms of local recurrence.

Materials and methods: From 1999 to 2007, 2220 patients were treated with breast conserving surgery and intraoperative radiotherapy with electrons (21 Gy at 90% isodose) as sole treatment. The study population includes both patients treated outside and inside the clinical randomized phase III trial ELIOT. Out of 2220 patients, 255 (11.5%) presented ILC. We compared this group with patients having IDC, treated in the same period. The rate of local recurrences has been analyzed, with a minimum follow-up of 5 years. The role of patients and tumor features on local control has been evaluated.

Results: Compared to IDC group, patients with ILC were older (≥ 70, 20% vs. 11%), with no lymph node involvement (pN0, 79% vs. 70%), low grading (G1-2, 86% vs. 72%), absence of vascular invasion (81% vs. 98%), higher hormonal receptor status (ER+, 97% vs. 88%), HER2 negativity (96% vs. 89%), low proliferative index (Ki-67, 23% vs. 44%). No differences were noticed with regard to the technical parameters of ELIOT. On the whole, the incidence of local relapse was 4.5% at 5 years (0.9/100 per year). Within the first 5 years of follow-up, no differences were observed between lobular and ductal histology, but after 5 years the difference became significant (p 0.05). Higher risk of local relapse was also observed in old patients (over 60) with ILC.

Regarding the biomolecular classification, lobular carcinomas belonging to Luminal A subtype had a more aggressive local behavior than Luminal A ductal carcinomas, showing a significantly higher rate of local relapse (p 0.0021).

Conclusion: In spite of a favorable tumor profile, a greater incidence of local relapse occurred in tumors with ILC compared to ductal histology. When considering the anagraphic, histological and biomolecular variables, the old age (>60), the proliferative index and the luminal A subtype turned out to be significant. Interestingly, the incidence of local relapse becomes statistically significant 5 years after the treatment. This event points out the importance of an adequate follow-up length, especially in lobular histology for which other reports on whole breast irradiation in literature describe similar biological behavior.
Title: Simultaneous integrated boost incorporated into a hypofractionated regimen using tomoDirect: Acute toxicity assessment

Maria Cristina Leonardi¹, Anna Morra¹, Federica Cattani¹, Luigi Santoro¹, Samantha Dicuonzo¹, Raffaella Cambria¹, Rosa Luraschi¹, Alessia Bazani¹, Roberta Lazzari¹, Veronica Dell'Acqua¹ and Roberto Orecchia¹,². ¹European Institute of Oncology, Milan, Italy and ²University of Milan, Milan, Italy.

Body: Aim: We report on acute toxicity, which is the secondary endpoint of a phase II clinical trial specifically addressed to assess the chronic toxicity of a hypofractionated scheme including a simultaneous integrated boost, with intensity modulated radiotherapy.

Materials and methods: From 2/2012 to 12/2013 194 patients with early breast cancer entered a phase II study on hypofractionated radiotherapy including a boost dose to the tumor bed. All patients were operated on conservatively. The whole breast and the tumor bed are planned to receive a dose of 45 Gy and 50 Gy, respectively, in 20 fractions, over 4 weeks. Treatment plans are generated using the TomoDirect modality, which is available on Tomotherapy Hi-Art System (Madison, WI). Acute toxicity was evaluated according to the RTOG acute toxicity scale, up to 6 months after the treatment. Afterwards, chronic toxicity is evaluated using LENT/SOMA scale.

Results: 95% of the volume of the breast and boost PTVs received 99% and 100% of the planned dose, as median values, respectively and 0.1% (median value) of the entire breast volume received 100% of the boost dose. The median maximum dose to the breast and to the boost PTVs was 113% and 103.3%, respectively. At the end of treatment, the acute toxicity, was distributed as follows.

As far as erythema was concerned, at the end of treatment, 58% of the patients experienced grade 1 erythema, which dropped to 23% one month later. Grade 2 erythema affected 37% of the cases, and after one month, it decreased to 2%. Only 1 patient (0.5%) complained of Grade 3 erythema at the end of the treatment, which rapidly disappeared afterwards. With regard to breast oedema, at the end of treatment grade 1 was observed in 16% of the cases, for whom it tended to remain stable after one month, while grade 2 oedema was noted in 4% of the cases, decreasing to 1.5% on the first month follow-up visit. Regarding desquamation, dry desquamation (grade 1) was observed in less than 10% of cases at the end of treatment, but it tended to increase to 17% one month later. Patchy moist desquamation (grade 2) was present in 1.9% of the patients at the end of radiotherapy, and in 1% of them, one month afterwards. Confluent desquamation (grade 3) was noted only in 1 patient (0.5%), who was receiving concomitant chemotherapy with cyclophosphamide, methotrexate and fluoruracil: it was still present 1 month after the radiotherapy completion, as the patient continued to be on chemotherapy. No significantly different side effects were observed between the whole breast and the boost area. No patients experienced any lung and cardiac symptoms.

Conclusion: The clinical results of this SIB hypofractionated scheme showed low acute toxicity. In spite of the high dose per fraction, with the tumor bed receiving an even higher dose per fraction, acute toxicity was within the limit acknowledged by literature for conventional fractionation. This non-rotational treatment option allows us to deliver treatment with a traditional tangent-like dose, without spreading low doses to the adjacent structures. Chronic toxicity will be assessed after 2 years. Therefore, a longer follow-up is needed to assess the effective tolerance to the SIB schedule.
Title: Tangential fields (TgF) breast radiotherapy (RT): Prospective evaluation of the dose distribution in the sentinel lymph node area (SLNa) as determined intra operatively by clip placement

Yazid Belkacemi¹, Veronique Bigorie², Quiong Pan¹, Romain Bosc², Ryan Bouaita¹, Frederic Pigneur³, Elias Assaf⁴, Hakima Badaoui⁵, Emmanuel Itti⁶ and Elie Calitchi¹. ¹APHP, Henri Mondor Breast Center, UPEC; ²APHP, Henri Mondor Breast Center, UPEC; ³APHP, Henri Mondor Breast Center, UPEC; ⁴APHP, Henri Mondor Breast Center; ⁵APHP, Henri Mondor Breast Center and ⁶APHP, Henri Mondor Breast Center, UPEC, Creteil, France.

Body: Purpose:
The coverage of axilla contents by radiation therapy (RT) is an important issue in the new era of minimal axillary surgery based on sentinel lymph node biopsy (SLNB). Data from recent trials demonstrated equivalent survival in breast cancer (BC) patients with 1-2 positive SLNs with or without axillary lymph node dissection (ALND). In a similar context, AMAROS trial showed that complete RT coverage of the axilla is a better option than ALND regarding the risk of arm lymphedema. Our recent data showed that axillary levels are underdosed when only tangential fields (TgFs) are used (Belkacemi et al, Ann Oncol 2013). We aimed to evaluate the dose distribution in the SLNa defined intra operatively by clips placement. This could be a important for patients with SLN involvement who have neither ALND nor RT to the axilla.

Materials/Methods:
Twenty-five patients have been prospectively included in this study. They had clips placement in the SLNa during the SLNB procedure. Breast dose was ranged between 40 to 50Gy in 15 to 25 fractions. Additional boost to the tumor bed of 10 or 16Gy was delivered in 21 patients. Level I-III and organs at risk were contoured using the RTOG contouring atlas. The SLNa was defined as 1.5 cm in diameter around the clips. Dose-volume-histograms were analyzed regarding the volumes receiving 95% or 50% of the prescribed dose. Percentages overlap between TgFs and SLNa volume were analyzed to define 3 groups: 100% overlap ("suitable group" with SLNa completely included in the TgF), > 50% overlap ("partially suitable group" with SLNa partially included in the TgF) and 0-49% overlap or completely outside the TgFs ("unsuitable group").

Results:
The mean dose delivered to levels I, II, III and SLN area were 25, 5, 2 and 33Gy respectively. The volume covered by the 95%-isodose were respectively 2%, 0%, 0% and 4%. The average dose delivered to level I, II, III and SLN area were higher using High TgFs vs STgFs (38 vs 22Gy, p=0.004; 11 vs 3Gy, p=0.019; 5 vs 2Gy, p=0.003; 43 vs 31Gy, p=0.02), respectively. HTgFs covered better 50% of all axilla levels. Boost delivery and initial tumor site did not influence axilla coverage by the TgFs. The SNLa was totally or partially covered in 48% and 28% of patients, respectively. The mean dose delivered to 95% of the SNLa was only 22Gy using STgFs and 33Gy with the HTgFs. Using the STgFs, the SNLa was either totally (n=8/20) or partially (n=6/20) covered by > 50% of dose. Average dose was 46, 34 and 8Gy, respectively in the 3 groups. HTgFs allowed a complete coverage of the SLNa in all patients.

Conclusion:
In patients undergoing breast conservative therapy, TgFs provide a limited coverage of the SLNa. STgFs allowed total coverage of this area in less than half of the patients. Thus, SLNa should be delineated in patients who have only SLNB procedure. Some of these patients with nodal involvement without additional ALND could benefit from HTgFs irradiation or a better-personalized nodal RT using a dedicated nodal RT technique such that reported in AMAROS trial. The last allow better coverage of the axilla contents than TgFs.
Title: Patterns of practice of regional node irradiation in the sentinel node biopsy era: Results of the nodal radiotherapy (NORA) survey. On behalf of the EORTC Breast Working Party of the Radiation Oncology Group (ROG)

Yazid Belkacemi, Orit Kaidar-Person, Philippe Poortmans, Mahmut Ozsahin, Maria-Clara Valli, Nicola Russel, Ian Kunkler, Julie Hermans, Abraham Kuten, Geertjan van Tienhoven and Helen Westenberg. 1 APHP, Henri Mondor Breast Center, UPEC, Creteil, France; 2 Rambam, Haifa, Israel; 3 Institute Verbeeten, Tilburg, Netherlands; 4 CHUV, Lausanne, Switzerland; 5 Oncology Institute, Southern Switzerland, Switzerland; 6 The Dutch Cancer Institute, Amsterdam, Noord-Holland, Netherlands; 7 Edinburgh Cancer Centre, University of Edinburgh, Edinburgh, United Kingdom; 8 EORTC Breast Working Party of the Radiation Oncology Group (ROG), EORTC, Brussels, Belgium; 9 Italian Hospital and Rambam Campus, Haifa, Israel; 10 Academisch Medisch Centrum, Amsterdam, Noord-Holland, Netherlands and 11 Radiotherapeutisch Samenwerkingsverband Arnhem-Nijmegen (Radian), Locatie Arnhems Radiotherapeutisch Instituut (ARTI), Arnhem, Netherlands.

Body: Objective:
Predicting the outcome of breast cancer (BC) patients based on sentinel lymph node (SLN) status without axillary lymph node dissection (ALND) is a matter of debate, especially when it comes to the definition of regional nodal irradiation (RNI). This is even unclear in the framework of primary systemic therapy (PST). The aim of the NORA (NOdal RAdiotherapy) Survey was to examine the patterns of RNI practiced by European Radiation Oncology centers.

Methods:
A web questionnaire was distributed to EORTC centers, and responses were received during the period between July 2013-January 2014.

Results:
A total of 81 European and 3 non-European answers were analyzed. While 3D planning is performed in 81 (96%) of the centers for breast irradiation, nodal areas are delineated in only 51 (61%) of the centers. After breast conserving surgery (BCS), only 14 (17%) centers declared to treat systematically the internal mammary chain (IMC), when supraclavicular node RT (SCN-RT) is indicated. Extra-capsular extension (ECE) is the main factor impacting decision-making regarding IMC and axillary nodal RT (ALN-RT). Only half of the centers advocate SCN-RT for intermediate risk patients (1-3N+). For macro-metastatic SLN involvement, there was a significant impact of ECE on decision-making independently from the number of positive LNs. In the PST setting, only 49 (58%) centers take into account the histologic fibrotic changes of the axillary LNs in post-PST ypN0 patients with unknown pre-PST status. In ypN0 patients with inner and central BC, 32 (39%) and 23 (27%) centers centers indicate SCN-RT and IMC-RT, respectively. SCN-RT is delivered by 30, 44, 58, 67 centers in patients with ypN(i+), ypN(mi), 1-2N+ and > 3-4N+ disease, respectively. ALN-RT is indicated by in 25% of the centers in patients with ypN(mi) or 1-2N+. Older age > 70y was not considered as a limited factor for RNI.

Discussion:
The term of RNI is not uniformly defined in the literature. In the historic studies, RNI was dedicated to wide RT including whole lymphatic pathways of the breast. ALN and IMC RT indications have declined with the time during the last decades because of the risk of morbidity. However this practice is challenged by the recent RT trials that reported and increase of overall and distant metastatic survival with RNI and IMC delivery in high-risk N0 and inner-central tumors. In addition, AMAROS trial showed equivalence between axillary RT and ALND in SLN (mi+) patients. Taking these data altogether in the context of increased avoidance of ALND, future challenges should concern the multidisciplinary patients’ selection for RNI and better personalization of the lymphatic pathways RT according to the risk of locoregional and distant recurrences.

Conclusions:
The NORA Survey is unique by evaluating the impact of SLN status and PST on RNI decision-making. IMC RT is not frequently coupled to SCN-RT. ECE is the main factor impacting decision-making for RNI. Only 58% of the centers take fibrotic changes in the LNs into consideration in decision-making for RNI indications. Age is not considered as a limiting factor for prescribing RNI in Europe.

Title: Low utilization of hypofractionated radiotherapy for the treatment of early-stage breast cancer in the US

Yvonne M Mowery¹, Rachel A Greenup¹, Kevin Houck¹, Manisha Palta¹, Janet K Horton¹, Eun-Sil S Hwang¹, Julie A Sosa¹ and Rachel C Blitzblau¹. ¹Duke University Medical Center, Durham, NC.

Body: Background: Large randomized controlled trials have shown that hypofractionated whole breast irradiation (HF-WBI) is not inferior to or more toxic than conventionally fractionated whole breast irradiation (CF-WBI) for the treatment of early-stage breast cancer. Royal Marsden data were published in 2006 (10-yr), the Ontario trial was reported in 2002 (5-yr) and 2010 (10-yr), and the UK START trials were published in 2006 (5-yr) and 2013 (10-yr). We utilized the National Cancer Data Base (NCDB) to evaluate patterns of radiotherapy fractionation for early-stage, node-negative breast cancer in the U.S. We hypothesized that HF-WBI use would increase over time in response to emerging data supporting its use in this population.

Methods: We conducted a retrospective, population-based cohort study of women >18 years diagnosed with T1-2N0 invasive breast carcinoma and treated with breast-conserving surgery between 2004 and 2011. Radiotherapy was categorized as accelerated partial breast irradiation (APBI; 38-40 Gy/1-10 fractions), HF-WBI (40-56 Gy/15-24 fractions) or CF-WBI (50-66 Gy/25-40 fractions). Patients treated with alternate fractionation were excluded. Patterns of breast radiotherapy fractionation were compared using the chi-square test. Multivariable logistic regression was performed for patients diagnosed in 2011, the year with the highest levels of HF-WBI utilization.

Results: 217,789 patients in the NCDB met inclusion criteria. HF-WBI use increased over time, rising from 2.1% among eligible patients in 2004 to 15.1% in 2011, while APBI use remained low at <2%. Utilization of HF-WBI was significantly higher in academic centers than comprehensive community cancer centers and community-based cancer centers (p <0.0001). This pattern persisted when controlling for T-stage, hormone receptor/HER2-status, diagnosis year, and patient age >30 years. Table 1 shows frequency of HF-WBI use over time by center type. On multivariate analysis of patients diagnosed in 2011, the following factors were associated with higher use of HF-WBI: treatment at an academic center, older patient age, hormone receptor positivity, pT1 tumor size, and rural residence (Table 2).

Conclusions: Utilization of HF-WBI in the US is rising, but remains low overall despite level I evidence showing its non-inferiority to CF-WBI. Given the advantages of HF-WBI in terms of patient convenience and potential healthcare system costs, further research is indicated to explore disparities in HF-WBI utilization in the US and to guide education of breast cancer providers.

Recurrence rates, stratified by age and histology, for accelerated partial breast irradiation using strut-based brachytherapy: A report on 1005 patients

Catheryn Yashar, Deanna Attai, Ernest Butler, John P Einck, Steven E Finkelstein, Ben Han, Robert L Hong, Lydia T Komarnicky, Maureen Lyden, Sudha B Mahalingam, Constantine A Mantz, Nadim Nasr, Stephen S Nigh, Jondavid Pollock, Jay E Reiff, Daniel Scanderbeg, Margaret R Snyder, Jon Strasser and Robert Kuske.

Background: APBI is an integral part of many clinical practices, but the majority of data that exists is in the elderly and invasive patient groups. In order to understand APBI performance in other subgroups, we present a subset analysis by histology (DCIS & invasive) and age (<50, ≥50 to <60 and ≥60 yrs).

Methods: The SAVI Collaborative Research Group database has accrued APBI patients at 14 institutions treated with strut-based brachytherapy. All patients received monotherapy (34 Gy in 10 fractions), prescribed in the standard method. Patients were grouped into three age ranges, as well as by histology. Crude recurrence rates (ipsilateral, contralateral and distant) were analyzed and reported. Two subjects had ipsilateral recurrence, without localization (i.e., TR/MM vs ipsilateral elsewhere) and those were classified as TR/MM for the analysis. Patients were treated between 2007 & 2011.

Results: 1005 patients (1008 breasts) were included in this analyses (690 invasive, 285 DCIS, 30 unspecified). Median age was 64 yrs for all subjects, 65 yrs and 62 yrs for invasive and DCIS subjects, respectively. Nearly all patients were post-menopausal (89%), had tumor size <2.0 cm (88%), no positive nodes (92%), had negative margins (>2mm; 94%), were ER+ (90%) and received no chemotherapy (94%). The rates for these variables were almost identical for the invasive and DCIS subgroups (except for no chemotherapy (invasive=92%; DCIS=99%)). In contrast, hormone therapy was delivered to 53% of invasive and 41% of DCIS subjects. Median follow up (FU) was 38 and 34 mos for invasive and DCIS subject groups, respectively. Median FU was 40 and 29 mos for invasive (n=49) and DCIS (n=26) subjects of age <50 yrs, respectively. For subjects 50 to 60 yrs of age, median FU was 40 and 36 mos for invasive (n=119) and DCIS (n=74). Median FU was 37 and 34 mos for invasive (n=343) and DCIS (n=116) subjects >60 yrs, respectively.

For the entire cohort (=1008 breasts) there were 20 ipsilateral breast (only) tumor recurrences (2.0% IBTR failure rate) of which 13 were TR/MM, which was equivalent to the contralateral tumor rate (N=13). There were 3 distant failures in the entire cohort. For patients in the <50 yr group, there were 3 IBTR (3.26%) all of which were TR/MM (1 invasive subject, 2 DCIS subjects). There were 2 contralateral failures in the DCIS group and none in the invasive group of this age group. For patients in the 50-60 yr group, there were 8 IBTR (3.31%) 5 of which were TR/MM (3 invasive subjects, 2 DCIS subjects). There was 1 contralateral failure in the DCIS group and none in the invasive group. In the >60 yr group, there were 9 IBTR (1.34%) 5 of which were TR/MM (4 invasive subjects, 1 DCIS subject). There were 2 contralateral failures in the DCIS group and 7 in the invasive group.

Conclusions: In this large cohort of patients treated with strut-based brachytherapy, the crude rate of IBTR was low (1.3-3.3%) and not significantly different in the 3 age groupings analyzed. At 3 yrs median follow up, the absolute difference in IBTR was only 2% in women over age 60 versus 50-60 or younger than 50 years. Likewise, invasive and DCIS both had low IBTR, suggesting that guidelines may need to be revised for young age and histology criteria.
Title: Development of a photonumeric scale for acute radiation dermatitis in breast cancer patients

Dean Shumway¹, Eleanor M Walker², Nirav Kapadia³, Thy Thy Do¹, Kent Griffith¹, Mary Feng¹, Bonnie DePalma², Reshma Jagsi¹, Yolanda Helfrich¹, Erin Gillespie⁴, Alexandria Miller¹, Adam Liss¹ and Lori J. Pierce¹. ¹University of Michigan, Ann Arbor, MI; ²Henry Ford Hospital, Detroit, MI; ³Dartmouth-Hitchcock Medical Center, Lebanon, NH and ⁴University of California, San Diego, La Jolla, CA.

Body: Purpose
Scales for rating acute radiation dermatitis (ARD) are inconsistent and have not been validated despite decades of clinical use, making ARD difficult to report reliably. We sought to design a photonumeric scale to consistently describe ARD in breast cancer patients undergoing radiation (RT).

Methods
Patients undergoing RT for breast cancer were enrolled on a prospective study that included photographs and reporting of physician-rated erythema, hyperpigmentation, and CTCAE toxicity score at baseline and 2, 4, and 6 weeks after initiating RT. Erythema and hyperpigmentation were also quantified using a hand-held colorimetric device. Photographs were taken using a standardized protocol that included 3 views to fully assess the breast/chest wall, axilla, and inframammary fold. 209 photographs from 35 patients with white skin (Fitzpatrick skin types I-IV) and 369 photographs from 50 patients with skin of color (Fitzpatrick skin types V-VI) were clustered according to the apparent severity of ARD. Due to the prevalence of hyperpigmentation that obscured erythema in patients with skin of color, separate images were used to illustrate ARD in this population. Two photonumeric scales (for white skin and skin of color) were developed via an iterative process until group consensus was achieved. Four raters with experience in the evaluation of ARD in breast cancer patients used the photonumeric scale to independently score the entire collection of photographs, sequenced in random order. Intra- and inter-rater agreements were assessed using weighted kappa scores.

Results
Of the 35 patients with white skin, 20% experienced severe erythema, and 40% experienced dry or moist desquamation. Of the 50 patients with skin of color, 34% experience severe hyperpigmentation, and 48% experienced dry or moist desquamation. Using the photonumeric scales, we observed high intra-rater agreement for independent ratings of erythema or hyperpigmentation (70 to 89% agreement fraction, kappa 0.55 to 0.81) and desquamation (79 to 87% agreement fraction, kappa 0.52 to 0.64). Similarly, we observed moderate to high inter-rater agreement for independent ratings of erythema or hyperpigmentation (61 to 76% agreement fraction, kappa 0.40 to 0.62) and desquamation (69 to 84% agreement fraction, kappa 0.36 to 0.58). Quantitative measurements of erythema in white patients using colorimetry correlated strongly with photonumeric grade (correlation coefficient 0.76, p<0.001), as did physician-rated erythema at the point-of-care (p<0.001). Fitzpatrick score was not significantly associated with maximum photonumeric erythema grade (p = 0.14).

Conclusions
We report a new photonumeric scale with high intra- and inter-rater reliability for acute radiation dermatitis in breast cancer patients. To our knowledge, this is the first rigorously evaluated scale that is applicable to patients across the spectrum of skin pigmentation, including white skin and skin of color. The photonumeric scale will facilitate consistent reporting of acute radiation dermatitis in research and clinical settings using a simple, standardized instrument. Future work will include prospective real-time clinical validation with multiple raters and correlation with patient-reported outcomes.

Funded by a Munn Idea Grant (G011480).
Introduction:
Intra-operative radiotherapy (IORT) is increasingly being used for the treatment of low risk breast cancer. In the randomized TARGIT trial, late toxicity was not different between patients treated with IORT and external beam radiotherapy. Early toxicity of IORT has not been fully characterized.

Methods:
IORT with one dose of 20 Gy using the Intrabeam® device has been offered as an alternative to standard treatment as part of a single center prospective single arm trial. Patients over 60 years with clinically node negative, < 2 cm invasive duct carcinomas were eligible. Patients aged 50-60 years, patients with tumors 2-3.5 cm and patients with invasive lobular carcinomas were treated with IORT if they were not candidates for standard treatment.
For the present study information regarding complications occurring within the first year after surgery was analyzed. Patients treated between 2006 and 2012 were included in this analysis.

Results:
393 patients were treated from 2006 – 2012. 4 were lost to follow up. Median age was 70 years (55-90) and median clinical tumor size was 1.2 cm (5-30).
102 patients (26.2%) had a complication. Infections were most frequent. Misdiagnosis of radiation dermatitis as infection in some cases cannot be excluded. Clinically meaningful seromas occurred in 10.2% of patient and 8.2% had a wound dehiscence, possibly related to rupture of pre-existing seromas.

18 patients (4.6%) had a grade 3 complication. 2 patients (0.5%) had grade 4 radiation induced skin necrosis of small size and both resolved within 4 months. All other complications resolved completely (table 1). Risk factors for complications in this cohort will also be presented.

Conclusions:
Intra-operative radiotherapy was associated with a relatively high rate of clinically meaningful seromas and wound dehiscence and rare small size skin necrosis. Most complications were mild – moderate. 5% of patients experienced grade 3 or 4 complications, and all resolved completely. Further study of the factors predisposing to severe complications is warranted.
Title: Disease-free survival according to the use of postmastectomy radiation therapy after neoadjuvant chemotherapy

Himanshu Nagar¹, Dustin Boothe¹, Paula Ginter¹, Cristina Sison¹, Linda Vahdat¹, Sandra Shin¹, Michael Smith¹, KS Clifford Chao¹, Dattatreyudu Nori¹ and Mary Katherine Hayes¹. ¹Weill Cornell Medical College, New York, NY.

Body: Purpose: Determine predictors of recurrence for patients treated with neoadjuvant chemotherapy (NAC) and mastectomy according to the use of postmastectomy radiation therapy (PMRT).

Methods and Materials: An analysis of 161 clinically staged T1-T3/N0-N3 patients treated with NAC and mastectomy with and without PMRT at our institution from 2003 - 2010 was conducted. The Kaplan-Meier product limit method was used to estimate survival and time-to-recurrence rates and the log-rank test was used to compare groups. A Cox proportional hazard regression analysis was carried out for time-to-recurrence, RT, and their interaction in the model.

Results: The median follow-up period was 48 months and 18 patients developed a recurrence. The 5-year recurrence rate and overall survival was 16.1% (95% CI: 9.6%, 26.3%) and 93.6% (95% CI: 88.2%, 97.0%), respectively. Patients that underwent PMRT had a decreased risk of recurrence compared to patients who did not (HR=0.25, 95% CI: 0.097 to 0.661; p<0.005). The 5-year DFS rate for those who received PMRT was 91.3% (95% CI: 82.8% to 95.7%) and 64.8% (95% CI: 37.8% to 82.4%) for those that did not (p=0.0126). Among all clinicopathologic factors examined, pathologic T stage (ypT) and pathological N stage (ypN) significantly correlated with the risk of recurrence (p<0.05). Patients with any pathological nodal disease had an increased risk of recurrence compared to patients who were pathologically node negative (HR=7.196; 95% CI: 2.05 to 25.264; p<0.002).

Conclusion: Patients treated with NAC and mastectomy, but without PMRT had a higher risk recurrence with increasing ypT and ypN stages. PMRT may increase DFS.
Title: The utilization of hypofractionated breast radiotherapy in the United States between 2003 and 2011

Dezheng Huo¹, Yasmin Hasan¹ and Katharine Yao². ¹University of Chicago, Chicago, IL and ²NorthShore University HealthSystem, Evenston, IL.

Body: Background: Recently, several randomized trials have found that accelerated hypofractionated whole breast irradiation (HF-WBI) had equivalent local recurrence rates and disease-free survival, compared to conventional fractionated whole breast irradiation (CF-WBI). It is unknown if the pattern of care regarding HF-WBI has changed in the United States after the publication of these trials, given its administrative advantage.

Methods: Using data from the National Cancer Database, this study included 559,362 non-metastasic female breast cancer patients who received post-lumpectomy external beam radiotherapy to their breast or regional nodes. We examined the trend of HF-WBI use in the U.S. and factors related to its use using logistic regression models.

Results: Of patients receiving external beam radiotherapy, about 5% underwent HF-WBI. The most common HF-WBI dose schedule is 42.4-42.6 Gy in 16 fractions without or with boost radiation. There was a 20-fold increased trend in the use of HF-WBI, increasing from about 0.6% in 2003 to 13% in 2011 (p<0.0001). Among patients with pT1-2N0-1 disease, a subgroup for whom previous clinical trials of HF-WBI are mainly applicable, HF-WBI use increased from 0.6% in 2003 to 14% in 2011. Although not included in previous clinical trials, patients with ductal carcinoma in situ also experienced an increased use of HF-WBI, from 0.5% in 2003 to 12% in 2011. We found age was strongly correlated with HF-WBI use; the older a patient, the more likely she received HF-WBI. African Americans were less likely to use HF-WBI. Patients with low grade were more likely to receive HF-WBI than those with high grade and patients with negative nodes are more likely to received HF-WBI. Large volume, academic cancer centers are more likely to adopt HF-WBI than community cancer programs. Interestingly, patients who live at least 50 miles away from a cancer center are about 58% more likely to receive HF-WBI than patients living within 50 miles of a cancer center.

Conclusions: The utilization of hypofractionated radiotherapy significantly increased from 2003 to 2011 in the United States, which is presumably influenced by publication of several randomized trials. In 2011, HF-WBI accounted for more than 10% of all external beam radiotherapy for early breast cancer patients. Patient and facility factors impacted the patterns of HF-WBI use.
Title: Sustained acceptable cosmetic outcomes and local control following accelerated partial breast irradiation using CT-guided IMRT in the prone position: Results from a phase I/II feasibility study

Carmen Bergom¹, Phillip Prior¹, Kristofer Kainz¹, Natalya V Morrow¹, Ergun E Ahunbay¹, Alonzo Walker¹, X Allen Li¹, Tracy Kelly¹, Adam D Currey¹ and Julia White². ¹Medical College of Wisconsin, Milwaukee, WI and ²Ohio State University Comprehensive Cancer Center, Columbus, OH.

Body: Objective/Purpose
External beam accelerated partial breast irradiation (EB-aPBI) can have potential challenges in daily reproducibility, although it has broader potential use than aPBI using brachytherapy. Image-guide radiotherapy (IGRT) can improve daily reproducibility and allow smaller treatment margins. Our institution utilized IG-IMRT to administer EB-aPBI in the prone position in a Phase I/II study to increase dose homogeneity, conformality, normal tissue avoidance, and reliable targeting. Our preliminary results and toxicity were promising. Here we report final physician- and patient-reported cosmetic outcomes from this prospective trial.

Materials and Methods
Women with node-negative invasive breast cancer or DCIS, tumors less than 3.0 cm, a negative sentinel lymph node biopsy, and surgical clips demarcating the lumpectomy cavity underwent prone EB-aPBI using IG-IMRT on an IRB-approved phase I/II study. The lumpectomy PTV represented a 2.0 cm lumpectomy cavity expansion. 38.5 Gy was delivered in 10 fractions over 5 days, such that 95% of the prescribed dose covered greater than 99% of the PTV. Dose constraints for the whole breast, lungs and heart were met.

Results
Twenty patients were enrolled, with a median patient age of 61.5 and a mean tumor size of 1.0 cm. 35% of patients had DCIS. At a median follow-up of 18.9 months, 40% and 10% of patients had G1 and G2 fibrosis, respectively, and 95% of patients had good to excellent physician-assessed cosmesis. At a median follow-up of 60.0 months (range 54-79 months), physician-assessed cosmetic outcome was good to excellent in 80%, with 30% and 20% of patients experiencing G1 and G2 fibrosis. Patient-reported outcomes at one year yielded 90% of patients with good to excellent cosmetic outcomes. At 3 years, 75% of patients reported good to excellent cosmesis. Eighty-eight percent of patients were completely satisfied with the treatment and results, and 94% of patients would choose aPBI again. With one local recurrence, the actuarial five year rate of local control was 95%.

Conclusions
These data demonstrate that EB-aPBI in the prone position using IG-IMRT continues to yield acceptable cosmetic outcomes at longer term follow-up, and a very high percentage of patients would choose this treatment again. (Supported by Komen Grant: BCTR0504070).
Title: Evaluation of separation techniques and dosimetry of the inframammary fold during whole breast radiation therapy

Guy Jones¹, Peter Guion¹, Jason Cheng¹ and Aparna H Kesarwala¹. ¹National Cancer Institute, Bethesda, MD.

Body: Purpose/Objectives: The majority of patients receiving radiation therapy will experience some form of skin reaction, ranging from localized erythema to moist desquamation. Radiation dermatitis of the inframammary fold (IMF), the most common acute side effect of supine whole breast radiation therapy (WBRT), can be mitigated by separating the breast from the chest wall. The purpose of this analysis was an objective evaluation and comparison of practical and inexpensive separation techniques.

Materials/Methods: A breast phantom was created on a human torso phantom using tissue-equivalent bolus material. Four separation techniques were evaluated: 1) taping the inferior aspect of the breast to the shoulder or placing 2) 6" x 2" rolled bubble wrap, 3) a 6" x 1" x 1" styrofoam block, or a 4) 50 mL 2” diameter plastic conical tube in the IMF. For the control setup, the breast was not taped and nothing was placed in the IMF. Written and pictorial simulation instructions recorded by one radiation therapist were independently used by additional therapists to reproduce each setup, with medial and inferior measurements taken for comparison. Dosimetry of identical tangent 100 cGy WBRT fields was evaluated with thermoluminescent dosimeters (TLDs) placed at each of four locations: the ipsilateral IMF, the ipsilateral chest wall 5 cm inferior to the IMF, and 5 cm superior to the nipple of both the ipsilateral and contralateral breasts at the 12:00 position. Measurements and TLD data are reported as mean ± standard error of the mean of 3 separate TLD readings. One-way ANOVA and posthoc analyses were used to determine significance between groups with α for significance set at p ≤0.05.

Results: Compared to simulation, the average differences measured medially and inferiorly among the conical tube (10 ± 6 mm medial; 0.6 ± 0.2 mm inferior), styrofoam block (13 ± 8 mm medial; 1.2 ± 0.2 mm inferior), and bubble wrap (18 ± 4 mm medial; 0.6 ± 0.1 mm inferior) setups were not significant. The taping technique (0.2 ± 0.1 mm) was more reproducible inferiorly than the styrofoam block setup (p <0.01), but no different from the conical tube and bubble wrap setups. TLD readings demonstrated that the IMF received less of the prescribed dose with the taping (108 cGy ± 1.4%), styrofoam block (109 cGy ± 0.9%), or bubble wrap (110 cGy ± 0.9%) techniques compared to either the control (120 cGy ± 1.1%) or conical tube (121 cGy ± 0.4%) setups (each p <0.01). TLD readings from the three other locations were not significantly different between any of the setups.

Conclusions: The taping, styrofoam block, and bubble wrap setups were most effective in sparing dose to the IMF. The only difference in reproducibility was between the inferior aspects of the taping and styrofoam block setups, but taping had the disadvantage of being more invasive than the other setups. While this unique analysis did not reveal a single superior solution, the taping, styrofoam block, and bubble wrap separation techniques should be considered by radiation oncologists seeking practical, inexpensive, and easily-implemented solutions to mitigate IMF dermatitis in WBRT patients.
Title: Effects of statin use on skin toxicity during breast radiation therapy

Scott M Lieberman¹, Elizabeth Stone¹, Christopher Chen¹, Marlow Hernandez¹ and Leah Roberts². ¹Cleveland Clinic Florida, Weston, FL and ²Charles E Schmidt College of Medicine at FAU, Boca Raton, FL.

Body: Background: Recent San Antonio Breast Cancer Symposium abstracts have suggested that statin use confers a significant benefit in breast cancer risk reduction and specifically in the subset of inflammatory breast cancer. Additional studies evaluating the combination of statin use with various breast cancer treatments are currently on-going. The primary objective of this study was to determine the effects of statin use on acute skin toxicity during breast radiation therapy (RT). Methods: We performed a retrospective chart review of 325 patients diagnosed with breast cancer who underwent RT between 2004 and 2012. Of these, 227 patients were considered evaluable. Patients were excluded if the course of RT was fewer than 16 treatments. Patients were also excluded if follow-up at the end of RT was not obtainable. Of the evaluable patients, 46 were on statins at time of RT, while 181 were not. Patients were evaluated at two time points - midway through RT and at completion of RT. Skin reactions were measured using the RTOG grading system for acute radiation morbidity. Grade 1 reactions were erythema and slight skin atrophy. Grade 2 indicated follicular, faint or dull erythema/ epilation/dry desquamation/ decreased sweating. Grade 3 was tender or bright erythema, patchy moist desquamation/moderate edema. Lastly, Grade 4 was ulceration, hemorrhage, necrosis. Results: Our results showed a statistically significant increase in acute radiation skin toxicity in patients on statins at the time of radiation therapy. By the midway point of RT, 67% of the statin group had developed Grade 1-3 skin toxicity vs. only 42% of the control group. Odds ratio midway through RT was 2.75. By the completion of RT, 94% of the statin group compared with 67% of the control group had Grade 1-3 skin toxicity (p=0.005). Odds Ratio at completion of RT was 7.29. The statin group also progressed to more advanced stages of toxicity more rapidly than our control group. Grade 1 skin reactions were seen in 62% of our statin group vs. 41% of our control group midway through treatment (p=0.044). Grade 2-3 reactions were seen in almost 5% of patients in the statin group vs. 1% in the non-statin group midway through treatment. At the end of treatment, 48% of patients on statins had developed Grade 2-3 reactions when compared with 29% in the non-statin group (p=0.0199). These results still remained significant when controlled for chemotherapy use. Conclusion: Our study revealed that patients on statins developed acute skin toxicity at higher rates than our control group. These results were statistically significant at both the midway point as well as at the completion of RT. Study limitations include the small sample size and the retrospective nature of the study. Our data also raises the question of what effect statins may have on local recurrence rates as well as the potential effects of radiosensitization in various breast cancer cell lines. These results are hypothesis-generating and require larger retrospective analyses or prospective trials to verify this effect.
Title: Prospective study of proton radiotherapy for treatment of regional lymphatics in breast cancer

Julie A Bradley¹, Roi Dagan¹, Meng Wei Ho¹, Christopher G Morris¹, Zuofeng Li¹ and Nancy P Mendenhall¹. ¹University of Florida Proton Therapy Institute, Jacksonville, FL.

Body: Purpose: To compare dosimetric endpoints between proton therapy (PT) and conventional radiation and to determine the feasibility of PT for regional nodal irradiation (RNI) in women with breast cancer.

Methods: From May 2012 to February 2014, 18 women (stage IIA-IIIB) prospectively enrolled on a pilot study. Median age was 51.8 years (range, 42-73), with equal division between breast-conserving therapy (BCT) and mastectomy and right and left-sided cancers. Treatment targets (CTVs for breast/chest wall, supraclavicular, axillary, internal mammary nodes [IMNs]) and organs at risk were delineated on CT scans, and PT and conventional plans were developed. PT alone was used for 10 patients (9 post-mastectomy, 1 after BCT) and combined proton-photon in 8 (all BCT). Acute toxicity was prospectively recorded using CTCAE v4.0. A Wilcoxon signed-rank sum test compared the dose-volume parameters.

Results: Median followup was 10.6 months (range, 1.1-19.1). For all patients, the PT plan better met the dosimetric goals and was used for treatment. Breast/chest wall coverage was adequate (V47.5=96.6% for both plans). PT improved coverage of level II axilla (median D95, 48.9Gy [range, 44.8-51.4Gy] with PT vs 45.4Gy [range, 39.8-51Gy] with conventional; p=0.0005). Adequate coverage of IMNs was consistently achieved with PT (median D95, 48.9Gy with a range of 44.8-51.4Gy) but not with conventional (median D95, 45.4Gy with range of 39.8-51Gy; p=0.0005); PT reduced heart dose in all patients. Median ipsilateral lung V5 measured 35.3% for PT compared to 60.5% for conventional (p<0.0001). Ipsilateral lung V20 improved with PT (median, 21.6% vs 35.5%; p<0.0001).

Grade 3 dermatitis developed in 4 patients (22%), which was the only grade 3 toxicity. All patients developed grade 2 dermatitis; other acute grade 2 toxicities included fatigue (n= 6) and esophagitis (n=5). No grade 4+ toxicities developed. Dermatitis resolved by 1 month after PT for all but 1 patient who developed cellulitis (grade 2).
Conclusion: PT for RNI after mastectomy or BCT significantly improves cardiac dose especially for left-sided patients and lung V5 and V20 in all patients without excessive acute toxicity. PT simultaneously improves target coverage for the IMN and level II axilla, which may positively impact long-term survival in breast cancer patients.
Title: Safety of eribulin mesylate and concomitant palliative radiotherapy for metastatic breast cancer: A single-center experience

Icro Meattini¹, Vieri Scotti¹, Carla De Luca Cardillo¹, Beatrice Detti¹, Vanessa Di Cataldo¹ and Lorenzo Livi¹.
¹Radiotherapy-Oncology Unit, Florence University Hospital, Florence, Italy.

Body: Background. Eribulin mesylate is a recently approved new therapeutic option for patients with metastatic breast cancer (BC). It is a structurally simplified synthetic analogue of halichondrin B that inhibits the growth phase of microtubule dynamics and sequesters tubulin into non-productive aggregates, inhibiting microtubule polymerization, and inducing irreversible mitotic block at G2-M phases and apoptosis.

Three phase II trials of eribulin in chemotherapy pretreated advanced BC patients were completed. In all these studies, eribulin showed a manageable tolerability profile, with most of the common drug-related adverse events being neutropenia, fatigue, alopecia, nausea, and anemia, according to the phase I trials findings. Eribulin was also associated with an overall low incidence of peripheral neuropathy.

When new chemotherapy options become available, one of the most important questions regarding the sequence of treatments is to address the safety of concomitant radiation treatments. Recently has been reported a clinical case treated with eribulin mesylate and whole-brain radiotherapy (RT) in a heavily pretreated patient with multiple visceral and bone metastases from triple negative breast cancer.

In our knowledge this is the first analysis focusing on the safety of eribulin in patients concomitantly treated with palliative RT.

Methods. All patients where heavily pretreated for metastatic breast cancer (≥4 previous chemotherapy lines), including anthracyclines and taxanes-based regimens. Patients received eribulin mesylate (1.4 mg/m2 i. v., on days 1 and 8, of a 21-day cycle).

Tumor response was assessed using the Response Evaluation Criteria in Solid Tumors (RECIST), every 8 weeks, or sooner if disease progression was suspected.

Safety was assessed according to National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE), version 4.0. Measures of bone-pain scores and analgesic consumption were evaluated at each visit, using a patient-rated scoring system.

Results. Concerning 25 consecutive treated patients, median performance status at baseline was 2 (range 1-3). A median of 4 cycles of eribulin (range 2-10) were administered. All patients received palliative bone RT during eribulin treatment. No suspension or delay in chemotherapy administration was necessary. 20/25 cases underwent spinal bone irradiation; 8 Gy in single fraction was given in 13/25 patients, 12 cases received 20 Gy in 5 fractions.

The overall response rate was 24% and the clinical benefit rate was 40%. Toxicity was manageable and in line with main published series; the most frequent grade 3 hematologic adverse events were neutropenia (56%), and anemia (20%).

Bone pain scores fell within a few weeks and remained below baseline value throughout the analysis. The mean pain score was 2 at baseline and 0.7 at the end of observation period. The mean analgesic score was 1.8 at baseline and 1.6 at the end of follow-up.

Conclusions. Our clinical practice experience supports the evidence that eribulin has clinical activity and is characterized by a manageable safety profile, also when combined to palliative RT. Concomitant treatment is feasible also in patients heavily pretreated, and with poor performance status.
Title: Comparison of cardiac dose between accelerated partial-breast irradiation and whole-breast irradiation in breast cancer patients

Kazuhiko Sato¹, Yoshio Mizuno¹, Hiromi Fuchikami¹, Naoko Takeda¹, Takahiro Shimo², Jun Kubota², Yuko Inoue³, Hiroshi Seto⁴ and Masahiro Kato². ¹Tokyo-West Tokushukai Hospital, Akishima, Tokyo, Japan; ²Tokyo-West Tokushukai Hospital, Akishima, Tokyo, Japan; ³Inoue Ladies Clinic, Tachikawa, Tokyo, Japan and ⁴Seto Hospital, Tokorozawa, Saitama, Japan.

Body: [Background] Breast-conserving surgery (BCS) followed by whole-breast irradiation (WBI) has now become the standard treatment for early-stage breast cancer. However, WBI is associated with an increased risk of coronary events, especially in patients with preexisting cardiac risk factors. In radiotherapy (RT), the highest dose is likely delivered to the left anterior descending artery (LAD), which is the typical site for ischemic heart disease. We initiated a prospective, observational study on accelerated partial-breast irradiation (APBI) using multicatheter brachytherapy after BCS. In this study, we compared the radiation dose to LAD between patients receiving APBI and those receiving WBI.

[Methods] The study participants included a cohort selected from consecutive patients who underwent BCS followed by RT since November 2007. In the WBI group, patients received 50 Gy in fractions of 2 Gy to the entire breast. APBI was initiated on the day of primary surgery in the form of multicatheter brachytherapy, at a dose of 32 Gy in 8 fractions. The planned target volume was defined as the estimated tumor volume plus a 20-mm margin. Dose distribution analysis was performed on the basis of postoperative CT using dose–volume histograms. LAD was outlined from its origin to each visible end using the planning CT images. First, the mean and maximal total doses to LAD were calculated. Second, the radiotherapeutic biologically effective dose of APBI was adjusted to that of WBI for comparisons between the two different RT schedules.

[Results] Of the 359 consecutive patients who underwent BCS followed by RT, we retrospectively reviewed 182 patients for radiation dose to LAD. The 82 patients receiving WBI were randomly selected; 42 patients had right breast cancer and 40 had left breast cancer. We selected 100 consecutive APBI patients with left breast cancer treated between September 2009 and December 2013 because the LAD dose is considered to be virtually zero in right breast cancer patients. In the WBI patients, the mean and maximal total LAD dose were significantly higher in left breast cancer patients (2.1 ± 0.8 and 8.2 ± 1.2 Gy, respectively) than in right breast cancer patients (0.4 ± 0.02 and 0.6 ± 0.03 Gy, respectively; p < 0.0001). Among the APBI patients, the total LAD doses were influenced by tumor location. The mean and maximal total LAD doses were significantly higher in patients with inner quadrants or central tumors (2.5 ± 0.2 and 4.4 ± 2.5 Gy, respectively) than in those with outer quadrant tumors (1.0 ± 0.1 and 2.1 ± 0.3 Gy, respectively; p < 0.0001). After adjustment for the total LAD dose, the mean and maximal total LAD doses were significantly decreased in APBI patients with outer quadrant tumors (1.1 ± 0.2 and 2.4 ± 0.4 Gy, respectively; p < 0.0001), but not in those with central and inner quadrant tumors (2.9 ± 0.3 and 5.4 ± 0.6 Gy, respectively).

[Conclusions] Our results show that APBI may decrease the risk of coronary artery disease, especially in patients with outer quadrant tumors in the left breast. Although APBI should be carefully interpreted until mature phase-III data are available, the risk of ipsilateral breast tumor recurrences and LAD dose must be considered together while administering RT after BCS.
Title: Clinical outcomes according to elective nodal irradiation and molecular subtypes in high risk N1 breast cancer patients

Jeong Il Yu¹, Won Park¹, Doo Ho Choi¹, Seung Jae Huh¹, Seok Jin Nam¹, Seok Won Kim¹, Jeong Eon Lee¹, Won Ho Kil¹, Young-Hyuck Im¹, Jin Seok Ahn¹, Yeon Hee Park¹ and Eun Yoon Cho¹. ¹Samsung Medical Center, Seoul, Korea.

Body: Objectives: To evaluate the clinical outcomes according to the application of an elective nodal irradiation (ENI) and molecular subtypes in high-risk pathologic N1 (pN1) breast cancer.

Methods: We performed a retrospective comparison study with high-risk pN1 patients who received curative resection followed by chemotherapy at Samsung Medical Center from January 2009 to June 2011. High risk was defined as having more than two of the following risk factors: ≥2 axillary lymph nodes (ALNs) or level II ALN metastasis, lymphovascular invasion and extracapsular extension. We compared clinical outcomes according to the application of ENI.

Results: Among 278 patients, 159 patients received ENI while 119 did not and their characteristics were displayed.

In both univariate and multivariate analysis, ENI, adjuvant chemotherapy and endocrine therapy were the significant prognostic factors in recurrence-free survival (RFS). ENI showed higher RFS than no ENI when they were analyzed according to molecular subtypes, except HER-2 enriched. RFS was 96.9% at 3-years in luminal A patients with no ENI.

**Conclusions:** The application of ENI may improve RFS in patients with high-risk pN1 breast cancer, so ENI should be considered in those patients. Close observation without ENI might be an option in patients with luminal A who had received optimal systemic managements.
Title: Skin toxicities of obese African American breast cancer patients treated with hypofractionated radiation therapy

Arun G Paul¹, Amy Collins², Gregory Dyson² and Neha Amin³. ¹Detroit Medical Center, Detroit, MI; ²Barbara Ann Karmanos Cancer Center, Detroit, MI and ³Wayne State University, Detroit, MI.

Body: Objective: Hypofractionated radiation therapy (HFRT) for early stage breast cancer is an established treatment option with equivalent cancer outcomes and better cosmetic results than standard fractionation. There is limited published information about expected skin changes of African-American breast cancer patients (pts) undergoing HFRT. While HFRT is not recommended for women with large breasts, the use of prone position may allow for homogeneous HFRT plans. We prospectively monitored and reported on skin changes in African-American pts who received HFRT for their breast cancer.

Methods: A retrospective analysis at a single institution from 12/2012 to 08/2013 was performed to identify early stage breast cancer pts who underwent breast conservation surgery and received adjuvant whole-breast HFRT. An assessment form had been created to prospectively document weekly changes in radiation dermatitis (CTCAE V.4 Grade 0-4) and hyperpigmentation (none, faint, moderate, severe). Photographs of the treated area were collected before and at the end of treatment. Treatment planning guidelines were per RTOG 1005.

Results: There were 15 African-American pts with Tis-T2N0M0 breast cancer who were treated with HFRT to a dose of 4256 cGy in 16 fractions (266 cGy per fraction) followed by a lumpectomy cavity boost of 1000-1250 cGy (250cGy per fraction). There were 12 (80%) pts with right-breast cancer and 6 (40%) who were treated in the prone position. The median age was 61 (36-70). The median body mass index (BMI) for the pts treated in the prone position (42.2 [36-54]) was greater than the median BMI for pts treated in the supine position (29.7 [26-43]). The median breast volume of the prone pts (2335cc [2163-3369]) was more than twice the median volume of supine pts (920cc [231-1459]). The median separation distance for prone and supine pts were 25.1cm (17.5-31.2) and 22.5cm (17.5- 31.8), respectively. Radiation dermatitis: None (6%), Grade 1 (60%), Grade 2 (34%), Grade 3 (none). Only three pts had desquamation:1 pt had dry, and two pts had both dry and minimal moist desquamation in the infra-mammary fold. Hyperpigmentation: none (6.5%), faint (40%), moderate (47%), severe (6.5%). The areas of severe hyperpigmentation correlated to areas of desquamation. The median DMax, mean heart dose, and ipsilateral lung V20Gy were 107.2% (105.2 – 109.9), 60 cGy (29 – 544), and 8.25% (0.0 – 23), respectively.

Conclusion: African-American pts treated with HFRT experience minor skin toxicities with mostly Grade 1 dermatitis and moderate hyperpigmentation changes. Obese African-American pts can safely be treated with HFRT if they can be placed in the prone position. Some pts with a separation of > 25cm can be safely and effectively treated with HFRT.
Title: Phase II trial of hypofractionated post mastectomy radiation

Matthew M Poppe¹, Bruce G Haffty² and Atif J Khan². ¹Huntsman Cancer Hospital, University of Utah, Salt Lake City, UT and ²Rutgers Cancer Institute of New Jersey & Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ.

Body: Purpose: The efficacy of irradiating the chest wall and draining lymph nodes after mastectomy in improving local regional control has been firmly established by multiple trials comparing mastectomy alone to mastectomy with postoperative radiation. The currently accepted standard of care involves 25 fractions of chest wall and nodal radiation plus an optional 5 fraction scar boost. Given recent publications with intact breast radiation demonstrating equivalence with shorter course radiation treatment, we sought to establish a short course of radiation for women post mastectomy that would be equivalent to conventional radiation in terms of local control and complications.

Methods: Starting in 2011, Stage II and III, unilateral breast cancer patients were prospectively consented to participate in our study at Rutgers Cancer Institute of New Jersey and the University of Utah. We designed a phase II non-inferiority trial, with plans to enroll 65 patients, allowing for a 18% loco-regional recurrence rate if the true rate is 10%. Patients were allowed to receive chemotherapy before or after adjuvant radiation with radiation starting 14-63 days after surgery or adjuvant chemotherapy. Patients underwent 3D simulation and were treated with ≥ 6MV photon radiation using 3D conformal tangents or intensity modulation. Regional nodal radiation was included when clinically appropriate with inclusion of internal mammary nodes at the treating provider’s discretion. The prescription dose was prescribed at 333cGy per day to the chest wall and regional nodes for 11 daily fractions followed by a recommend scar boost of 333cGy per day for 4 fractions. Chest wall PTV was keep within 90-115% of the prescribed dose, the maximum brachial plexus dose was keep below 3919cGy (107%) and no portion of the heart could receive >2Gy/day. The maximum dose of the boost field was kept to 120% of the boost prescription. Any breast reconstruction technique was allowed, per institutional standard.

Results: 48 patients have thus far been enrolled with a median follow up interval of 17 months. Looking at the 43 patients with > 4 months of follow-up, we have only seen a 4.7% grade 3 or greater acute or late toxicity rate, with one grade 3 wound complications, and one grade 3 fibrosis. There has been one chest wall recurrence, for a 2.3% local recurrence rate. Conclusion: Early results would appear to show that hypofractionated post mastectomy radiation appears to be safe and feasible. Acute toxicity is less than anticipated, however it is too early make any conclusions on efficacy or late effects, with only 48 out of 65 patients enrolled. We hope to use the results of this phase II trial to design a randomized prospective trial comparing hypofractionated post mastectomy radiation to standard fraction.
Title: Effect of margin width on local recurrence in invasive lobular carcinoma treated with multimodality therapy

Yasuaki Sagara, William T Barry, Ines Vaz-Luis, Fatih Aydogan, Jane E Brock, Eric P Winer, Mehra Golshan and Otto Metzger-Filho. Brigham and Women's Hospital, Dana-Farber Cancer Institute, Boston, MA and Dana-Farber Cancer Institute, Boston, MA.

Body: Background: Recent consensus guideline on margins for breast conserving surgery recommends the use of no ink on tumor as the standard for an adequate margin. Current recommendation extends to invasive lobular carcinoma (ILC), however the data in this subset is limited by small numbers. In the present analysis we sought to evaluate the influence of margin status on outcomes in ILC and mixed tumors.

Methods: We performed retrospective cohort study and reviewed 809 eligible patients diagnosed with ILC (337 with pure ILC; 472 with mixed ILC) with Stage I –III treated at Dana Farber/Brigham and Women’s Cancer Center (DFBWCC) between May 1997 and Dec 2007. Clinico-pathologic data was extracted following the Clinical Research Information Systems (CRIS) Database procedures and manually reviewed to confirm inclusion and details of margin status. Margin status was defined using the last ASCO/ASTRO/SSA consensus guidelines criteria. Analysis results were considered to be statistically significant when the two-tailed p-value was <0.05.

Results: Breast conservation was performed in 399 patients (49%). Margin status at the initial attempt for breast conservation was defined as follows: 180 (45%) negative, 64 (16%) positive, 71 (18%) ≤ 1mm margin, and 84 (21%) close margins (> 1 and < 3 mm). Following initial lumpectomy, 102 (25%) patients underwent additional surgery (96 re-excisions and 6 mastectomies) and residual invasive disease was found in 40 patients. Whole-breast radiation therapy was performed in 376 patients (96%). In multivariate models adjusted for classic clinico-pathologic factors, tumor size (HR= 1.8 95% CI 1.0 to 3.3, p=0.05), multifocality (HR= 2.0 95% CI 1.1 to 3.6, p= 0.02) and ILC subtype (HR= 2.0 95% CI 1.0 to 3.7, p=0.04) were correlated with positive margins, while year of diagnosis, age and pre-surgical MRI findings were not statistically significant.

With 72 months median follow-up, 12 ipsilateral breast cancers (3.1%), 5 other locoregional (1.2%) and 15 distant (3.8%) recurrences were observed after definitive breast conserving therapy. The incidence of locoregional recurrence (LRR) was 4.3% and similar for ILC and mixed ILC (p=0.76). In univariate analysis positive surgical margin was associated with LRR (HR=5.1, p= 0.03) and disease-free survival (DFS) (HR=8.9, p≤ .001), but due to limited number of cases and events this could not be adjusted for other clinico-pathologic prognostic factors in a multivariate model. Close surgical margins, margins within 1mm and multifocality were not associated with increased LRR or worse DFS. Re-excision did not impact on DFS for patients with close margin (p= 0.57) and within 1 mm margin (p= 0.85). By contrast, significant improvement of DFS following re-excision was observed in patients with positive margin (p= 0.01).

Conclusions: Following lumpectomy, local recurrence rates for ILC patients with close surgical margin and ≤ 1mm margin are low and equivalent to those in patients with negative margins. This study supports the validity of using no ink on tumor as the standard for an adequate margin for patients diagnosed with pure or mixed ILC treated with multimodality therapy.
Title: Multidisciplinary breast cancer care is associated with a higher rate of breast conservation in comparison with non-multidisciplinary care

Caitlin L Gomez1, Pin-Chieh Wang1, Nicole A Dawson1, Robyn L Dvorak1, Nova Foster1, Anne Hoyt1, Sara A Hurvitz1, Amy Kusske1, Charles Y Tseng1 and Susan A McCloskey1. 1University of California, Los Angeles, CA.

Body: Background
Mastectomy rates, both therapeutic and prophylactic, are on the rise in the United States. After recent implementation of a multidisciplinary breast clinic for newly diagnosed women at our institution, we sought to examine the impact of multidisciplinary care on surgical decision making.

Materials/Methods
Women with newly diagnosed breast cancer at our institution are referred to a multidisciplinary breast clinic where they are seen by a team of breast specialists (MDC) or to an individual practitioner (non-MDC) for initial consultation. We retrospectively analyzed rates of breast conserving surgery (BCS) and mastectomy among women with newly diagnosed breast cancer seen in either setting. For mastectomy cases, we designated the mastectomy as clinically indicated vs not clinically indicated based on National Comprehensive Cancer Network (NCCN) guidelines for breast conservation. T-test and chi-square were used to examine the comparability between MDC and non-MDC cohorts. Logistic regression was used to evaluate the overall prevalence of BCS among MDC and non-MDC cohorts. Stratification analysis was further conducted to examine BCS rates among women in each cohort receiving neoadjuvant chemotherapy vs up front surgery.

Results
A total of 341 consecutive patients were analyzed, including 202 MDC and 139 non-MDC patients seen in initial consultation between June 2012 and April 2014. The MDC and non-MDC cohorts were statistically equivalent in terms of age, tumor and nodal stage, histology, biomarker status, receipt of neoadjuvant chemotherapy, and proportion with genetic mutations. In the MDC cohort, 66% underwent BCS vs 42% in the non-MDC cohort (p<0.0001). Of those receiving neoadjuvant chemotherapy, 37% in the MDC cohort underwent BCS vs 12% in the non-MDC cohort (p=0.08). Of those proceeding to surgery without neoadjuvant therapy, 70% underwent BCS in the MDC cohort vs 46% in the non-MDC cohort (p<.0001). Among mastectomies performed in the MDC vs non-MDC cohorts, 77% and 41% respectively were clinically indicated (P<.0001). Rates of unnecessary contralateral prophylactic mastectomy were comparable in both groups, 39% (p=0.99).

Conclusions
Breast cancer patients seen in an MDC setting at the time of initial diagnosis are significantly more likely than women seen in a non-MDC setting to undergo breast conservation. We hypothesize that the MDC model of breast cancer care, via facilitation of more informed medical decision making, may be a viable strategy to curtail rising mastectomy rates in the United States.
Title: Residual disease after breast conservation surgery: To excise or not to excise?

Catherine R Campo¹, Erika Reategui¹, Sarah P Cate¹, John Rescigno¹, Priyanka Mittar¹, Alyssa Gillego¹ and Susan K Boolbol¹. ¹Mount Sinai Beth Israel Medical Center, New York, NY.

Body: Background:
The definition of adequate margins after breast conservation surgery for invasive breast cancer has been a highly debated topic. A recent consensus statement by the SSO/ASTRO recommends re-excision only for positive margins, defined as tumor at ink. In light of this consensus statement, we studied the characteristics of patients undergoing breast conservation surgery with subsequent re-excision at our institution in order to examine factors predictive for residual disease (RD+) in the re-excision specimen, as well as a second re-excision.

Methods:
In this IRB approved retrospective chart review of our breast cancer cases from 1998-2013, we reviewed 828 patients who underwent breast conservation surgery with re-excision for invasive breast carcinoma. A close margin was defined as less than 2mm from the inked margins, and a positive margin was defined as tumor at ink. We analyzed various clinicopathologic features. RD+ was missing in 7 patients (0.8%), who were excluded from that analysis. Pearson chi-square was used to test significance in univariate analysis. Binary logistic regression was applied in multivariate analysis of factors significant at p<0.05.

Results:
Overall, 230 patients (28%) had RD+, and 103 patients required a second re-excision (12.4%) due to persistently positive or close margins (44% of RD+). Factors not significant for RD+ were: diagnosis era (before June 2007 vs. after), menstrual status, age < 40, race, excision volume, tumor size, nodal status, grade, histology, lymphovascular invasion, and hormone receptor status. For patients with only close margins, there was no difference in RD+ by margin width, as defined by <0.5mm, 0.5 to <1mm, 1mm to <2mm. Factors significant for RD+ were: disease that was mammographically occult or calcifications only (35%) vs. mass or architectural distortion (25%), p=0.003; positive margin vs. close margin (33% vs. 24%, p=0.004); margin positive or close for DCIS (41%) vs. both DCIS/invasive (30%) vs. invasive alone (17%), p<0.001; presence of DCIS (30% vs. 16%, p=0.001); extensive intraductal component (EIC) (42% vs. 24%, p<0.001); the number of positive or close margins (1: 16%, 2: 26%, 3+: 48%, p<0.001).

In multivariate analysis, the number of positive or close margins was significant, (p<0.001), as was a margin positive or close for DCIS (p<0.001). Factors significant in univariate analysis for a second re-excision were similar as those for RD+. In multivariate analysis, independent factors for second re-excision were: EIC (p=0.007), number of positive or close margins (p<0.001), and a margin positive or close for DCIS (p=0.001).

Conclusions:
Residual disease at re-excision for positive or close margins was present in approximately one-fourth of patients. The probability of residual disease was unrelated to margin positivity or margin width within 2mm. Consideration of re-excision should take into account the burden of intraductal disease in the specimen, its presence at or close to the margin, and the number of positive or close margins.
Title: Intraoperative ultrasound-guided breast conserving surgery for palpable and nonpalpable breast cancer

Guldeniz Karadeniz Cakmak, Ali U Emre, Oge Tascilar, Burak Bahadir and Selcuk Ozkan. 'Bulent Ecevit University School of Medicine, Zonguldak, Turkey and 'Bulent Ecevit University School of Medicine, Zonguldak, Turkey.

Body: Objective: Intraoperative ultrasound guided (IUG) breast conserving surgery (BCS) is being increasingly embraced by breast surgeons worldwide. Real-time sonographic localization provides tumor free margins with low excision volumes and decreases rate of reoperations. We aimed to compare the efficacy of IUG-BCS for palpable and nonpalpable breast cancer with respect to margin status, re-excision rate, tumor free tissue sacrifice and cost-time analysis. The relationship between intraoperative assessment of gross macroscopic and ultrasonographic margins and frozen section results, were also analyzed. Methods: Between 2011 and 2014, IUG-BCS were performed to 208 patients with the diagnosis of in situ or invasive carcinoma. Intraoperative localization protocol includes ultrasound visualization of the lesion, tumor margin determination, and image confirmation of specimen and tumor bed. Sonographic and macroscopic assessment of the surgical margins by surgeon was followed by frozen section analysis of each margin. Moreover, cavity shaved margins from tumor bed were also obtained for permanent section analysis.

Results: Of the 208 patients, 89 (42.8%) had palpable and 119 (57.2%) had nonpalpable tumors. The sensitivity of intraoperative ultrasound localization was 100% (208/208 cases). Patients were on average 55 years old (range, 25-92). There was no difference with respect to patient characteristics including age, menopausal status, personal-family history, oral contraceptive usage, body mass index and tumor localization. Mean tumor size was 1.14 cm for nonpalpable and 2.87 cm. for palpable tumors. Negative margins were achieved in 92.43 % of nonpalpable (110/119) and 91.01% (81/89) of palpable lesions at the initial procedure verified by frozen section analysis. The involved margins were correctly identified by the surgeon via specimen sonography in 95.4% of the cases (15/17). According to frozen section analysis of the 1248 ultrasonographically clear margins, re-excisions were required for 16 margins of palpable and 14 margins of nonpalpable tumors. The overall positive margin rate determined by frozen section analysis was 2.4% (30/1248), with the majority of these patients (12/17) proved to have significant degrees of pure DCIS or mixed invasive ductal with DCIS at final histopathologic evaluation. Three patients (2.5%) with nonpalpable and two patients (2.24%) with palpable tumors required a second operation for either determination of close margins or multifocality at cavity shaved margins, without residual cancer on pathological examination of the reoperative specimens. IUG-BCS resulted in smaller excision volumes in nonpalpable cancers due to their size, as expected. However, calculated resection ratio was found to be similar for both groups. A cost and time analysis determined nothing significant between groups.

Conclusion: IUG-BCS is an invaluable and effective modality for both palpable and nonpalpable breast cancer in obtaining clear surgical margins with optimum resection volumes and reducing re-operations. Furthermore, frozen section analysis of the specimen margins together with shaving cavity margins of the tumor bed for permanent analysis could be a feasible method for minimizing the requirement for reoperations.
**Title:** Intra-operative imaging of surgical margins in breast conserving surgery using localized tissue dielectric response

J Michael Dixon¹, Lorna Renshaw¹, Oliver Young¹, Dhananjay Kulkarni¹, Talha Saleem¹, Moshe Sarfaty², Ramaswamy Sreenivasam², Catherine Kusnick² and Jeremy Thomas¹. ¹Edinburgh Breast Unit, Edinburgh, Midlothian, United Kingdom and ²L S Biopath, Mountain View, CA.

**Body:**

**INTRODUCTION:**
Breast conserving surgery (BCS) removes the tumor with a surrounding margin of normal breast tissue, and to reduce local recurrence clear margins are needed. Involved margins identified by pathology several days later require a second operation. Between 20-40% of BCS patients require re-excision. There is a clear unmet clinical need for effective and efficacious intra-operative, real time assessment of breast tumor margins. The handheld, battery operated TOUCH Imaging device displays spatially resolved images of margins based on tissue spectral dielectric response. This novel imaging device enables surgeons to assess in real-time the status of the excised tissue margins.

**AIM:**
To determine the efficacy and safety of TOUCH Imaging device as used by surgeons during BCS and its health economics.

**METHOD:**
The 1st study of the TOUCH Imaging device was run in the USA with freshly excised breast tissue as part of BCS. The study was run in the pathology lab to determine the efficacy and safety of using the device. The efficacy was determined by surgeons interpretation of device generated margin images compared with permanent section pathology. A follow up study in the UK is currently underway. Surgeons were trained to use the device in the operating room on freshly excised tissue. The imaging was performed after the surgery was completed with no subsequent intervention. The margins were scored as clear or positive and the localization of the abnormality was marked using special ink for specific pathology attention. In the learning phase 18 BCS cases were performed. The main study is being run in two phases and is currently underway. Phase-1 aimed to determine the accuracy of the device when used by individual surgeons in real time had been completed. Analysis is on the way, and phase-2 will start following the confirmation of device accuracy and will involve using the device to direct intra-operatively which margins require further excision. Phase 2 will provide insight to the potential health economics of using the TOUCH Imaging device.

**RESULTS:**
Data from the first study in the USA on 50 BCS specimens, imaging 214 distinct margins are shown in the table. The sensitivity of the device is high; the false negative rate low, the specificity and false positive rates are satisfactory.

The training study in the UK on 18 BCS specimen results showed 50% True Positive, 39% True Negative, 11% False Positive, 6% False Negative rates. There were 5 cases (28%) of positive margins < 1 mm and the device images identified 4 with 1 case (6%) being missed.
Results from the ongoing study will be presented.

CONCLUSIONS:
• The TOUCH Imaging device is safe and efficacious.
• It is easy for surgeons to use in the operating room.
• This device has the potential to reduce BCS re-operation rate.
**Body:** Background: A positive margin status after breast conserving surgery (BCS) is one of the strongest predictors of local recurrence of intraductal and invasive carcinoma. As much as 20-50% of all patients with BCS need to undergo a second operation in order to receive free margins. In this study we tested the clinical performance of Margin Probe (Dune Medical Devices), a novel device for intraoperative margin evaluation.

Methods: A prospective clinical trial was performed: The device was applied to 150 lumpectomy specimen from consecutive patients with BCS treated during the first three months in 2013. The re-excision rate was compared to the re-excision rate of a historical group of 156 patients treated with BCS during the first three months in 2012, without the application of the device. We analyzed whether Margin Probe is affected by tumor morphology, grading, size of the tumor, breast density, age, body-mass-index or the use of wire-marker.

Results: Due to the application of Margin Probe the re-excision rate decreased significantly by 51% from 39.7% to 14.6%. In the subgroup of intraductal carcinoma (DCIS) the re-excision rate was reduced about two thirds from 66.7% to 23.1%. In the subgroup of invasive lobular carcinomas the re-excision rate decreased from 37.0% to 19.0%. Margin Probe results are not affected by grading, tumor size, breast-density, age, body-mass-index or wire-marker application.

Conclusion: Margin Probe is an effective tool for detection of positive margins during BCS and significantly decreases the re-excision rate. It is not limited to invasive carcinoma but also detects involved margins in DCIS as well as in invasive lobular carcinoma. It does not interfere with any of the factors we examined.
Title: Translating the concept of intrinsic subtypes into an oncoplastic cohort of more than 1000 patients-predictors of recurrence and survival

Mahdi Rezai¹, Stephanie Kellersmann², Sarah Knispel², Rainer Kimmig¹ and Peter Kern¹². ¹Breast Center Düsseldorf, Düsseldorf, North-Rhine Westfalia, Germany and ²University Hospital of Essen, Essen, North-Rhine Westfalia, Germany.

Body: Introduction:
The concept of breast cancer experienced a paradigm shift by Sørlie T. et al. with intrinsic subtypes as prognostic classification of breast cancer [1]. We validated this concept in a large cohort study of oncoplastic surgery.

Patients and methods:
We analysed 1035 patients with oncoplastic surgery (2004-2009) and survival parameters related to histopathological approximated intrinsic subtypes.
Data were retrieved from customized questionnaires and patients charts. Survival data were determined from cancer registries.

Results:
A total of 944 patients with primary unilateral breast cancer, median age 58 years, were eligible for analysis. At a median follow-up of 5.3 years, LRR was 4.1%, with 5-year-OS of 94.5% and DFS of 90.9%. Stage distribution was as follows: T1a 3%, T1b 12 %, T1c 44,2 % and T2 was 22,1%. 70,4 % of patients were nodal-negative and nodal involvement was predominantly low. Intrinsic subtypes, not T-size, nodal-status, resection margin width nor histopathology, governed the prognosis of this cohort.
Triple-negative and Her2 non luminal breast cancer had the highest recurrence and the lowest survival rates compared to Luminal A: Recurrence TNBC 11,3 %, Her2pos non luminal 9,3 %, Luminal A 2,5 %; Overall survival: TNBC 91,3 %, Her2 non luminal 93,7 %; Luminal A: 96,3 %. Our data confirmed the intrinsic subtype concept on a large basis in oncoplastic surgery.

Body: Background
Breast cancer treatment is a multimodality treatment with different options for the individual patient, aiming to preserve the breast contour in the vast majority of the patients. Different treatment modalities can be used for this goal: primary breast conserving surgery (BCS), BCS after neoadjuvant therapy and immediate breast reconstruction after ablative surgery. Which treatment strategy is chosen may depend on patient preferences as well as patient age. The aim of the present analysis was to describe the rate of breast contour preserving procedures (BCPP) as related to patient age.

Material and methods
All invasive M0 breast cancer patients diagnosed and operated in the Netherlands between 2011 – September 2013 were selected from the national NABON Breast Cancer Audit. Primary BCS rates, BCS rates after neoadjuvant therapy, and rates of immediate reconstructions after ablative surgery were calculated for various age groups: <40, 40 to 50, 50 to 70 and ≥ 70 years.

Results
A total of 34,577 patients were identified. Sixty percent (20,583 patients) underwent BCS. Primary BCS rates increased with age: 47%, 60%, 69% in patients aged <40 years, 40 to 50 years and 50 to 70 years, respectively. In patients aged ≥ 70 the BCS rate was considerably lower (48%). Immediate reconstructions were performed in 16% of all mastectomy patients. An inverse relationship was observed with patient age; the rate of immediate reconstructions decreased from 38% in patients <40 years to 1% in patients ≥70 years of age. A similar decrease in neoadjuvant therapy was seen over the various age groups in patients treated with BCS from 21% to 4% in patients <40 and ≥70, respectively.

The table shows different treatment modalities. After combining these outcomes the rate of breast contour preserving surgery was similar in patients aged <70 (62-73%).

</tbody>
</table>

* Proportion of patients with primary breast conserving surgery, breast conserving surgery after neoadjuvant treatment and immediate reconstruction combined with mastectomy.

Conclusions
Patient age affected both the BCS with or without neoadjuvant therapy and the percentage of immediate reconstructions after mastectomy. Overall, more similar percentages in preservation of the breast contour are achieved for various age groups compared to BCS alone. Therefore, combining different treatment modalities into breast contour preserving surgery provides a more complete overview of maintaining the breast contour related to various age groups than BCS alone.
Title: Magnetic sentinel node and occult lesion localization in breast cancer: Initial results of the MagSNOLL trial

Muneer Ahmed\textsuperscript{1,2}, Ashutosh Kothari\textsuperscript{2}, Hisham Hamed\textsuperscript{2}, Sumit Goyal\textsuperscript{3}, Tibor Kovacs\textsuperscript{2}, Anand David Purushotham\textsuperscript{1,2}, Bauke Anninga\textsuperscript{1,2}, Phillipa Young\textsuperscript{3}, Julie Scudder\textsuperscript{2}, Sarah McWilliams\textsuperscript{2}, Sarah Pinder\textsuperscript{1,2}, Quentin Pankhurst\textsuperscript{4}, Ian Monnypenny\textsuperscript{3} and Michael Douek\textsuperscript{1,2}. \textsuperscript{1}King's College London, London, United Kingdom; \textsuperscript{2}Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; \textsuperscript{3}University of Wales at Llandough, Cardiff, United Kingdom and \textsuperscript{4}University College, London, United Kingdom.

Body: Trial registration:
ISRCTN: 68689512
MREC No: 13/LO/0636
UKCRN ID: 14979

INTRODUCTION:
One-third of breast cancers diagnosed are non-palpable. These breast cancers require localization-guided surgery and axillary staging using sentinel lymph node biopsy (SLNB). We present our experience of the first 20 patients undergoing a novel technique of magnetic-guided lesion localization and concurrent SLNB, avoiding the need for wire-guided localization and radioisotopes.

MATERIALS AND METHODS:
Co-localization of the primary tumour and sentinel lymph nodes (SLNs) using a novel magnetic technique was initially undertaken on a protocol-driven predefined minimum of 10 patients with palpable breast cancers to assess the feasibility of the magnetic tracer to safely localize at the point of injection and concurrently drain to the lymphatics. In order to confirm proof of principle, the subsequent 20 patients with non-palpable breast cancers were analysed. An ultrasound-guided intra-tumoral injection of magnetic tracer was performed (0.5 mL Sienna+, Endomagnetics Ltd, UK). Once successful lesion localization was confirmed (peak magnetometer counts retained at the site of injection), the technique was undertaken in patients with non-palpable breast cancers awaiting wide local excision and SLNB. All patients underwent SLNB with the magnetic and combined technique (radioisotope and Patent Blue Dye).

RESULTS:
A total of 33 patients were recruited and 1 patient excluded due to breach of the trial protocol. This left a remainder of 32 patients for consideration, of which 12 patients (1 bilateral) possessed palpable breast cancer and 20 patients non-palpable breast cancer. Peak magnetometer counts were retained at the site of injection in all palpable (n=13) and non-palpable (n=20) breast cancers. Re-excisions (second operations) for involved margins were performed in 2 patients with non-palpable breast cancers (10%). The mean volume of excised specimens was 49 cm\textsuperscript{3} (SD 30.6). The SLN identification rate for the magnetic technique alone was 84\% (28/33) overall and 85\% (17/20) for non-palpable lesions. For the combined technique (radioisotope and blue dye) the SLN identification rate was 97\% (32/33) overall and 100\% (20/20) for non-palpable lesions. When the magnetic technique is combined with blue dye, the SLN identification rate overall was 97\% (32/33) and for non-palpable breast cancers was 95\% (19/20). The mean number of sentinel nodes excised was 1.75 versus 2.05 for the magnetic and combined techniques respectively.

CONCLUSION: Magnetic lesion localization and concurrent SLNB is a feasible technique. Further optimisation and validation of this technique, in a larger trial, is required.
Title: Anticipating ACA's impact on breast cancer screening for medically underserved women reached through the Avon Breast Health Outreach Program: Understanding the Massachusetts experience

Lindsay Senter¹, Marvin R Aliaga¹, Yixin Hu², Kelly Morrison Opdyke¹, Kathryn Gates-Ferris¹ and Marc Hurlbert³. ¹Cicatelli Associates Inc (CAI), New York, NY; ²Mailman School of Public Health, Columbia University, New York, NY and ³Avon Foundation for Women, New York, NY.

Background
The Avon Breast Health Outreach Program (BHOP) supports community-based organizations to conduct education and outreach to link low-income and uninsured women to routine breast cancer screening and care. Through the Affordable Care Act (ACA), the number of uninsured individuals is expected to decrease as of 2014. While ACA implementation varies by state, BHOP grantees may benefit from understanding the health reform experience in Massachusetts (MA) in 2006 and its impact on the number and proportion of uninsured clients served over time.

Objective
Describe changes in client volume, health insurance status, and demographics following implementation of health reform in MA to anticipate upcoming impact of ACA on BHOP grantees.

Methods
Confidential client intake records of continuously funded BHOP grantees from 2004-2012 were analyzed; dataset included females aged 40-64, recruited for breast cancer screening. We compared records for 11,199 clients served by 4 ‘MA’ BHOP programs with 283,720 clients served by 52 ‘control’ agencies funded in the US during the same time period. We examined trends across years in agency-specific rates of health insurance coverage, and client volume adjusting for annual funding. Changes in key demographic characteristics over time were also analyzed.

Results
The proportion of uninsured MA clients decreased dramatically from 46.6% to 6.2% from 2004-2012, with the biggest decrease occurring in the 3 years following health reform (42.1% to 13.0% from 2006-2009); as compared to only a slight drop among controls from 2004-2012 (69.3% to 67.4%). After adjusting for changes in annual BHOP funding, MA experienced a 74% increase in client volume from 2006-2009, compared with a 15% increase among controls. From 2004-2012, the mean age of clients (53 years) remained stable and similar for MA and controls. The proportion of racial/ethnic minorities served increased considerably in MA, from 62.0% to 77.7%, versus a smaller increase of 60.1% to 63.0% in controls. Likewise, the proportion of clients born outside the US rose from 37.2% to 50.7% in MA, compared with 33.7% to 36.6% among controls. However, the proportion of low-income clients (annual household income <$25,000) decreased overall from 90.4% to 83.1% in MA, and from 83.1% to 79.1% for controls.

Conclusion
In BHOP, Massachusetts observed a marked decrease (most noticeably in the 3 years following health reform) in the proportion of uninsured clients served, while overall client volume and the proportion of racial/ethnic minorities and foreign-born women increased.

Discussion
Historically, many BHOP grantees have relied on funding from the CDC’s National Breast and Cervical Cancer Early Detection Program or charity funds to pay for screening services for uninsured clients. As more clients nationally gain access to health insurance, BHOP grantees need to be prepared for the changing landscape and potential increase in client volume, as experienced by MA. Additionally, grantees should plan to update systems that aid in health insurance eligibility determination, assist with enrollment, and strengthen provider partnerships and referral systems that accept multiple types of insurance.

Title: Adaptive and acquired mechanisms of resistance to PI3K inhibitors

Sarat Chandarlapaty, Maurizio Scaltriti, Marie Will, Zhiqiang Li, Ana Bosch-Campos, Sarit Schwartz, Vanessa Rodrik-Outmezguine, Michael Berger, Baselga Jose and Neal Rosen. 1Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Background: Activation of PI3K alpha is among the most frequent oncogenic events in breast transformation, commonly occurring through mutations in the p110 alpha subunit of PI3K or amplification of the HER2 receptor tyrosine kinase. Therapeutic targeting of activated PI3K signaling has been made feasible by the development of highly selective and potent ATP competitive inhibitors of p110 alpha some of which are in late stage clinical development. Unfortunately, clinical response to these compounds has not been seen for the majority of patients and when response occurs it is often short-lived. We have hypothesized that relief of feedback regulation of PI3K signaling constitutes a major mechanism for tumor cell adaptation to inhibitors of oncogenes such as PI3K.

Methods: To understand the basis for resistance to PI3K inhibitors we studied the consequences of acute and prolonged PI3K inhibition in patient samples as well as in cell line and murine models of breast cancer. We examined the effects of selective inhibition of PI3K alpha on upstream and parallel signaling pathway components utilizing several phosphoproteomic methods including mass spectrometry, antibody microarrays, and immunoblotting. We further investigated the consequences of PI3K inhibition upon the genome using next generation sequencing.

Results: In the context of tumors with high levels of RTK signaling such as HER2+ breast cancers, inhibitors of PI3K alpha led to only transient inhibition of PI3K/AKT signaling with reactivation of signaling closely coinciding in time with loss of feedback suppression of RTKs such as HER3 and IGF1R. This reactivation of AKT signaling could be blocked using inhibitors of the induced RTKs and this was associated with a marked increase in tumor cell death. A second mechanism of reactivation of PI3K signaling was observed in examining the genomes of tumors where inhibition of PI3K alpha was associated with acquired inactivating mutations in PTEN. Loss of PTEN in such tumors was associated with failure of the PI3K alpha inhibitor to block PI3K/AKT signaling but sensitivity to combined PI3K alpha plus PI3K beta inhibition in laboratory models. Finally, in the context of hormone dependent tumor models, inhibition of PI3K alpha was associated with an increase in estrogen receptor activation. This was observed as increases in ER protein expression, ER phosphorylation, and ER binding to established ER target promoters. Combined inhibition of ER and PI3K alpha was demonstrated to be synergistic in these models in vivo.

Conclusions: Feedback suppression of upstream and parallel signaling pathways poses a major limitation to the antitumor effects of single agent PI3K alpha inhibition. Combination approaches to potently inhibit PI3K alpha, PI3K beta, and either ER or HER3/IGF1R may prove more effective and durable in the clinic.
Title: Impact of a culturally syntonic door-to-door breast cancer early detection intervention

Carmen J Calfa¹, Julie G Wilkinson², Mindy M Williams³, James M Pann⁴, Angela Yehl⁵, Stephanie E Hoogenbergen⁶ and Andrea D Ivory⁶. ¹Memorial Cancer Institute, Hollywood, FL; ²ImmunoSite Technologies, Miramar, FL; ³Memorial Division of Breast Surgical Oncology, Hollywood, FL; ⁴Nova Southeastern University, North Miami Beach, FL; ⁵Nova Southeastern University, Fort Lauderdale, FL and ⁶Women's Breast Health Initiative Florida Affiliate, Miami Lakes, FL.

Body: Introduction. Disparities in the detection of breast cancer persist despite efforts to reach underserved populations and increase mammography utilization. Black and Hispanic women are more likely to be diagnosed at a later stage compared to White women. Lack of health insurance and limited awareness of breast cancer are significant predictors of screening behaviors; other reasons remain poorly understood and warrant further research. Our study presents highlights of the Women’s Breast Health Initiative Florida Affiliate (WBHI) intervention and key findings related to its impact.

Methods. The intervention targeted single-family home neighborhoods with high incidence of late-stage breast cancer, median income at 200% of the poverty level, and access to affordable health clinics. Neighborhood mobile mammography or transportation to local facilities was provided, followed by navigation to assure proper follow up. Eligible women were uninsured, ≥40 years of age and were qualified for an annual screening mammogram.

During 2011-2012

*culturally relevant & trained

Descriptive and inferential statistical methods were used to analyze participant data divided into 3 groups based on neighborhood racial demographics: “Black” or “Hispanic” data groups had ≥75% Black or Hispanic residents respectively, while the “Other” did not have a predominant race. Post-visit phone surveys of 1,871 participants were conducted within 30 days.

Results. The intervention significantly increased screening rates amongst eligible women from 22% to 64%, had a 0.24% breast cancer diagnosis rate and motivated 59% of the women to propagate awareness. Health insurance coverage rates did not differ significantly between the 3 groups. Notably, amongst the insured, those from “Hispanic” neighborhoods had the highest recent mammogram rate while, amongst the uninsured, those from “Black” neighborhoods had the highest. Neighborhood culture and prior mammogram history impacted the efficacy of the intervention. Among the “Hispanic” and “Other” groups, women with no prior mammograms were less receptive to receiving one compared to those who had prior mammograms. This phenomenon was not observed in the “Black” group. Women’s responses and perceived benefit to the educational package differed according to the neighborhood race and ethnicity:

**Discussion.** WBHI reached the goal of increasing screening rates in this underserved population, thus showing that this type of intervention can be effective. Educational packages presented in a face-to-face format within a door-to-door context were found useful by most women. Our findings highlight disparities beyond a woman’s access to breast healthcare and education by showing that neighborhood culture impacts response to outreach intervention and breast healthcare. This generates the hypothesis that given equal access to care, disparities in using screening mammography will remain. Educational methods further tailored to racial and ethnic characteristics may play a significant role in closing disparity gaps.
Title: Association of BRCA1 mutations with impaired ovarian reserve: A plausible connection between infertility and breast/ovarian cancer risks

Sara B Giordano¹, Navdha Mittal², Kristin Smith² and Mary Ellen Pavone². ¹Medical University of South Carolina, Charleston, SC and ²Northwestern University, Chicago, IL.

Body: Purpose: Mutations in either the BRCA1 or BRCA2 gene are associated with breast and ovarian cancer susceptibility. Lifetime risk estimates for ovarian cancer in the general population indicate that 1.4 percent (14 out of 1,000) of women will be diagnosed with ovarian cancer compared with 15 to 40 percent (150-400 out of 1,000) who have a BRCA1 or BRCA2 mutation. For decades, scientists have been attempting to establish a link between the risk of developing cancer and infertility. One prospective study suggested an association with BRCA1 mutations and occult primary ovarian insufficiency. This study showed a novel association between low response to ovarian stimulation and BRCA1 mutations, suggesting a link between double-strand DNA break repair dysfunction, infertility, and breast/ovarian cancer risks.

If substantiated, this may place BRCA mutation positive women at higher risk for chemotherapy induced ovarian failure. We also know that reproductive factors including low parity and infertility may place women at increased risk for breast cancer. Taking into account that 1% of females suffer from primary ovarian insufficiency and that the underlying mechanism remains unknown most of the time, discovery of susceptibility gene may have implications for understanding the link between infertility and breast/ovarian cancer.

We hypothesize that mutations in the BRCA1 gene will adversely affect ovarian reserve, as measured by AMH levels.

Participants and Methods: Subset analysis of serum samples taken from Northwestern Ovarian Cancer Early Detection Program (NOCEDPP) of reproductive aged women who had testing for the BRCA mutation. Using an IRB approved protocol, the NOCEDPP database was searched for women 18-45 years old who had previous BRCA testing. These women must have also provided consent for their stored serum to be used for research purposes. We excluded those with a BRCA2 mutation, a previous history of cancer and/or cancer treatment, and those with a previous unilateral or bilateral oophorectomy or other ovarian surgery. Statistical analysis was done using parametric and nonparametric testing.

Results: A total of 125 met the criteria for our study. 66 women were BRCA1 mutation-positive and 59 were BRCA mutation-negative. The median age for BRCA1 mutation-positive women was 33.5 years while BRCA mutation-negative patients was 37 years (p<0.05). Body mass index, gravidity, parity, and duration of birth control were similar between the groups. Overall median AMH values were 2.6ng/mL in both groups. However, when broken into age groups, BRCA1 mutation-positive women aged 35-39 had a significantly lower AMH level when compared to BRCA mutation-negative women (median 3.6ng/mL vs 1.3ng/mL, p<0.05).

Conclusion: AMH values were significantly lower in BRCA1 mutation-positive women aged 35-39. Women with the BRCA1 mutation should be counseled regarding this potential decrease in ovarian reserve.
**Title:** Formative evaluation of interventions addressing culturally relevant needs of young breast cancer survivors

Rochelle Shoretz¹, Adina Fleischmann¹, Elana Silber¹, Mary Ann Hall² and Ashani Johnson-Turbes². ¹Sharsheret, Teaneck, NJ and ²ICF International, Atlanta, GA.

**Body:** Background. Young women diagnosed with breast cancer face challenges impacting their quality of life, psychosocial functioning, and reproductive health outcomes. Ashkenazi Jewish women experience a disproportionately high prevalence of genetic mutations in the BRCA1/2 genes linked to a higher incidence of hereditary breast and ovarian cancer, and have unique needs based on genetic risk and cultural factors. Sharsheret, a national not-for-profit organization with an expertise in supporting Jewish young breast cancer survivors (YBCS), developed two interventions, the Peer Support Network (PSN) and Genetics for Life® (GFL), to address the culturally specific needs of Jewish YBCS. In 2011, Sharsheret conducted a formative evaluation to strengthen its existing PSN and GFL interventions.

Methods. Four focus groups were conducted with 27 YBCS having participated in the PSN or GFL. The groups investigated the information and support needs of YBCS of Jewish descent and YBCS perceptions of PSN and GFL content, materials and delivery channels. Two groups (online and in-person) investigated the needs of YBCS, PSN and GFL program content, and PSN and GFL program delivery related to the psychosocial health of YBCS. Two groups (online and in-person) explored YBCS needs, PSN and GFL program content, and PSN and GFL program delivery related to the reproductive health of YBCS. Participants were recruited using in-person methods, email blasts, social media and via Sharsheret website postings. Qualitative data were analyzed using a notes-based thematic analysis.

Results. Across groups, respondents identified the primary information needs for YBCS included resources addressing genetics, side effects and consequences of treatment (e.g., effects on fertility, intimacy and premature menopause) rather than treatment itself. Respondents identified that their support needs included culturally relevant peer support and genetic resources at the time of diagnosis, treatment and after treatment, as well as support for partners, family members and friends. Participants preferred to receive information and support through diverse modalities, including health care providers, the internet, peer supporters, support groups, symposia and teleconferences and mass media. Respondents recommended outreach efforts for the PSN and GFL interventions in locations that attract young people, including pediatricians’ offices, schools, salons, and college campuses, and to clergy, school principals, local Jewish organizations and health care providers. Participants also suggested potential technology-based modifications to PSN and GFL intervention delivery, including online intake forms, a LiveChat option, video testimonials, interactive expert column, online pedigrees and family conference calls with a genetic counselor or clinical staff member.

Conclusion. YBCS identified the PSN and GFL interventions as critical resources attentive to their culturally specific information and support needs. Focus group participants provided strategies to enhance intervention content and reach. Healthcare professionals serving YBCS of diverse backgrounds can utilize the data gleaned from this evaluation to shape culturally relevant interventions and materials to address the unique needs of YBCS.
**Body: Background**

Half of the patient treated with neoadjuvant chemotherapy (NAC) for a large operable breast cancer has no axillary lymph node involvement at the time of surgery. Sentinel lymph node detection (SLND), performed after NAC, must select patient who should be spared of an axillary lymph node dissection (ALND). The application of SLND for staging the axilla after NAC for patient who initially had a proven axillary lymph node involvement remains controversial because of a low detection rate (DR) and a high false negative rate (FNR).

**Objective**

The aim of GANEA 2 trial was to assess the DR and the FNR of SLND after NAC in the particular case of patients with a proven axillary lymph node involvement.

**Patients and Method**

GANEA 2 was validated by scientific and ethical national boards.

Inclusion criteria: FIGO stage T2-T3 infiltrating breast carcinoma, indication of NAC, surgery (radical or conservative) after NAC and signed consent form.

Exclusion criteria: inflammatory cancer, local relapse, previous surgical removal of the tumour, mental disorder, pregnancy or no contraceptive method, contra-indication to NAC, NAC interrupted due to progressive disease.

Design: Diagnosis and indication to plan a NAC, control of inclusion and exclusion criteria, consent form signature, axillary sonography with fine needle cytology before NAC to select patients with a proven lymph node involvement. After NAC patients underwent both SLND, with the combined technique Blue dye and radiolabeled colloid, and complementary ALND.

Pathological procedure: Pathological analysis, of sentinel and non sentinel nodes, carried out according to standard methods and classified according the last American Joint Committee staging system and Sataloff classification.

Studied parameters were detection rate, false negative rate and Sataloff grading on tumor and lymph nodes. We evaluated particularly the likelihood that the FNR in patients with one or more SLN examined was greater than 10%.

Patients with no lymph node involvement before NAC underwent only a SLND with an ALND only in the case of SLN macro-metastasis with a rigorous follow up. They are not part of this abstract.

**Results**

From July 2010, to February 2014, 242 patients from 19 institutions were enrolled, with a proven axillary lymph node involvement before NAC. After NAC, 1/3 had metastasis free axillary lymph node (80/142).

Detection rate was 83.1% (201/242). Half of the patients with a detection failure had an involved ALND. The false negative rate was 14.2% in the whole series but 24.5% in the case of only 1 SLN resected, and 8% in case of more than 1 SLN resected. In case of involved SLN, half of the patients had involved ALND. Considering the node Sataloff scoring, 18 of the 20 false negative cases were grade C or D (n=15 grade C, metastatic disease and therapeutic effect; n = 3 grade D, metastasis and no therapeutic effect).

**Conclusion**

Among patients treated by NAC for a large operable breast cancer with proven involved lymph node before NAC, who had only 1
SLN examined, the false negative rate was 24.5%. SLND with the combined technique, provides a FNR of less than 10% only in the case of 2 or more SLN resected.

Title: Methods impacting the false negative rate of sentinel lymph node surgery in patients presenting with node positive breast cancer (T0-T4,N1-2) who receive neoadjuvant chemotherapy – Results from a prospective trial – ACOSOG Z1071 (Alliance)

1Mayo Clinic, Rochester, MN; 2Alliance Statistics and Data Center, Mayo Clinic, Rochester, MN; 3University of Texas MD Anderson Cancer Center, Houston, TX; 4Alliance Statistics and Data Center, Duke University, Durham, NC; 5Magee-Womens Surgical Associates, Pittsburgh, PA; 6University of Wisconsin Hospital and Clinics, Madison, WI and 7Columbia University Medical Center, New York, NY.

Body: Background: The American College of Surgeons Oncology Group (ACOSOG) Z1071 trial (Alliance) reported a false negative rate (FNR) of 12.6% with sentinel lymph node (SLN) surgery after neoadjuvant chemotherapy in women presenting with node-positive breast cancer. Proposed methods to decrease the FNR include clip placement in the positive node at initial diagnosis with confirmation of resection of the clipped node at surgery and inclusion of residual metastatic cells identified by immunohistochemistry (IHC) for cytokeratins and disease measuring <0.2mm on H&E in the definition of node positivity after chemotherapy. Herein we evaluate the impact of these methods on FNR.

Methods: Z1071 was a prospective multi-institutional trial in which women with clinical T0-4,N1-2,M0 breast cancer underwent both SLN surgery and axillary dissection (ALND) after neoadjuvant chemotherapy. The primary endpoint defined nodal metastasis as disease >0.2mm on H&E. Slides were submitted for central IHC staining when H&E-negative, unless performed locally. For this analysis, we expanded the definition of node positivity to include metastases less than 0.2mm on H&E and metastatic deposits identified by IHC.

In 171 cases, a clip was placed in the node at initial biopsy and in these cases the SLNs and ALND were evaluated by x-ray or pathology to document clip location. FNR in the clip cohort is reported using the primary endpoint definition of node positive disease (>0.2mm on H&E).

Results: In the 113 cases where the clip was found in the SLN the FNR was 6.4% (1.8-15.5%). In the 29 cases where the clip was found in the ALND specimen, the FNR was 22.2% (6.4-47.6%).

IHC was available on 470 of 525 patients with cN1 disease and 2 SLNs resected. Using the definition of H&E metastasis >0.2mm, the FNR in these patients was 11.3% (34/301, 8.0-15.4%) which decreased to 8.7% (27/311, 5.6-11.8%) when including any disease <0.2mm. SLNs from 16 patients had disease <0.2mm in size. Seven patients previously classified as false negative SLN changed to true positive with identification of disease in the SLN. Nine patients changed from node-negative to node-positive with the only disease being <0.2mm disease found in the SLN. Nodal pathologic complete response rate changed from 36.0% to 33.8% with the inclusion of metastases <0.2mm.

Conclusion: Placement of a clip at initial diagnosis of node positive disease with identification of the clip during the SLN surgery
reduces the FNR. Use of IHC with inclusion of metastases <0.2mm in the definition of residual nodal disease in women with node positive breast cancer after chemotherapy also improves the accuracy of SLN surgery. Use of one or both of these methods should be considered when performing SLN in this setting.
Title: Sentinel node procedure before or after neoadjuvant chemotherapy in clinically node negative or positive patients; results from 3 phase III studies of the Dutch breast cancer trialists’ group (BOOG)

Vivianne C Tjan-Heijnen¹, Birgitte E Vriens¹, Maureen J Aarts¹, Judith R Kroep², Cock J van de Velde², Gerrit-Jan Liefers², Ayoub Charehbili², Petronella G Peer³ and Maaike de Boer¹. ¹Maastricht University Medical Centre, Maastricht, Netherlands; ²Leiden University Medical Center, Leiden, Netherlands and ³Radboud University Medical Center, Nijmegen, Netherlands.

Body: Background
In breast cancer patients treated with neoadjuvant systemic therapy, the timing of the sentinel node (SN) procedure in patients with clinically node-negative disease (cN0) at diagnosis and the role of the SN procedure after neoadjuvant therapy in patients with initially clinical node-positive disease (cN+) still remains to be elucidated.

Methods
Between February 2006 and May 2012, 657 patients were enrolled in three clinical trials on neoadjuvant systemic therapy under the auspices of the Dutch Breast Cancer Research Group (BOOG). In the INTENS and NEO-ZOTAC study, patients were treated with TAC or AC-T neo-adjuvant chemotherapy (doxorubicin (A), cyclophosphamide (C) and docetaxel (T)). In the TEAM IIa trial, patients were treated with neoadjuvant endocrine therapy (exemestane for 6 months). Timing of the SN procedure in cN0 disease mainly depends on local policy and period of inclusion. We compared the pN0 rate after SN procedure performed before versus after neoadjuvant systemic therapy, in patients with cN0 disease at initial diagnosis. Further, we assessed the SN negative and the false-negative sentinel node rate in patients with initially cN+ breast cancer and conversion to cN0 when treated with neoadjuvant systemic therapy. The false-negative rate was obtained by dividing the number of patients who were SN-negative but non-SN positive by the number of patients who had a positive SN or a positive non-SN.

Results
In total, 271 patients (n=93 INTENS, n=107 NEOZOTAC, n= 71 TEAM IIa) underwent a SN procedure (n=233 cN0; n=38 cN+). Of patients with cN0 breast cancer at diagnosis, 131 (56%) underwent the SN procedure before and 102 (44%) after neoadjuvant systemic therapy, with ypN0(sn) or ypN0(i+)(sn) in 90/131 (69%) and 69/102 (68%) patients, respectively. Patients with initially cN+ disease who converted to cN0 disease after systemic therapy had a negative SN in 29% (11/38) of cases. The false-negative rate was 20% (6 of 30). More detailed analyses will be presented at the meeting.

Conclusion
To our knowledge, this is the first study comparing the impact of the timing of the sentinel procedure in patients with cN0 disease. We showed, that irrespective of the timing of the SN procedure - before or after neoadjuvant systemic therapy - in patients with cN0 breast cancer at diagnosis, two-third of patients had a negative sentinel node. In patients who converted after neoadjuvant chemotherapy from cN+ to cN0 the false negative sentinel node rate was 20%.
Correlation of percutaneously biopsied axillary lymph nodes marked with black tattoo ink prior to neoadjuvant chemotherapy with sentinel lymph nodes in breast cancer patients

Nicole Choy1, Jafi Lipson1, Sunita Pal1, Debra Ikeda1, Long Trinh1, Kimberly Allison1, Michael Ozawa1, Amanda Wheeler1 and Irene Wapnir1. 1Stanford University School of Medicine, Stanford, CA.

Body: Introduction:
Sonographic evaluation of the axilla and percutaneous biopsy of abnormal lymph nodes with fine needle aspiration (FNA) or core needle biopsy (CNB) has become more common practice in patients with newly diagnosed breast cancer prior to neoadjuvant chemotherapy (NAC). Sentinel lymph node (SLN) biopsy is considered the gold standard for axillary staging in clinically node negative breast cancer patients. Currently, there is no clear correlation of sonographically detected abnormal lymph nodes and open surgical assessment. We conducted an exploratory pilot study which marked suspicious axillary lymph nodes with black tattoo ink at the time of percutaneous needle biopsy prior to NAC. Black nodes visualized during axillary surgery were evaluated in comparison to SLNs.

Methods:
Breast cancer patients with clinical and/or sonographically suspicious axillary lymph nodes prior to NAC were included in the study. Following FNA or CNB biopsy of node, 0.1 to 0.5 ml of a sterile, highly purified, biocompatible fine carbon suspension (Spot™) was injected into the cortex of the lymph node and adjacent soft tissue. A total of 12 patients were injected with black ink prior to NAC. Intraoperative presence of black pigment was assessed and correlation between sentinel and tattooed nodes were evaluated.

Results:
Nine patients had a positive percutaneous lymph node biopsy prior to NAC. The average number of days that elapsed between injection and to surgery was 130 days. A successful SLN procedure was performed in all patients. A black tattooed node was identified in all patients and correlated to a SLN. 7 patients were down-staged in the axilla and 6 patients did not go onto completion axillary dissection. One patient with a negative SLN had a completion axillary dissection, but no additional positive lymph nodes were found. Four patients with positive SLN had a completion axillary dissection (1 of whom was a false negative percutaneous biopsy). In all four patients, the positive sentinel node contained visible black ink. There was one patient who had an additional positive sentinel node, which was not black. Two axillary dissections contained additional positive nodes.

Conclusion:
Black ink tattooing with sterile black ink (Spot™), successfully marked suspicious lymph nodes prior to NAC. These correlated to a SLN. In node positive patients with a partial response in the axillary lymph nodes following neoadjuvant chemotherapy, previously marked, black-inked node proved to be the persistent positive node. Tattooing of lymph nodes at the time of percutaneous biopsy may improve the accuracy of surgical axillary staging by aiding in the intra-operative identification of previously biopsied nodes.
Title: In patients with breast cancer, pre-operative sentinel node biopsy using intradermal microbubbles and contrast enhanced ultrasound predicts volume of axillary metastases

Karina Cox¹, Jennifer Weeks¹, Ritchie Chalmers¹, Pippa Mills¹, David Fish¹ and Ali Sever¹. ¹Maidstone and Tunbridge Wells NHS Trust, Maidstone, Kent, United Kingdom.

Body: Introduction
In patients with early breast cancer, there is a trend towards conservative axillary surgery but there are concerns that patients with high volume axillary metastases may receive sub-optimal axillary treatment leaving them vulnerable to local recurrence. Determining the metastatic status of sentinel lymph nodes (SLN) in the pre-operative/diagnostic period would allow focused surgical planning and facilitate decisions regarding adjuvant therapy early in the patient pathway.

Methods
654 patients with primary invasive breast cancer and a normal grey-scale axillary ultrasound were included in the analysis. Pre-operatively, patients received periareolar intra-dermal injection of microbubble contrast agent, breast lymphatics were visualised by ultrasound and followed to identify axillary SLN. Contrast-pulse sequencing and grey-scale ultrasound modalities were used to image SLN. Sentinel lymph nodes were then subjected to core biopsy. Patients subsequently underwent tumour excision and axillary node clearance (ANC) or surgical sentinel node biopsy (SNB) using blue-dye and isotope +/- completion ANC.

Results
Sentinel lymph nodes were clearly visualised in 605 patients and successfully (B2-B5) core biopsied in 555. The test identified 53% of all SLN metastases with 100% specificity. The negative predictive value was 88%. The prevalence of axillary lymph node metastases was 23%. Given a benign (B2) SLN biopsy result, the post-test probability that a patient had SLN metastases on subsequent surgical excision was 12%. Following ANC, 55% of patients with a malignant (B4/5) biopsy result were found to have high volume axillary disease (2 macro metastases or more) whereas 21% of patients with an initial benign (B2) biopsy result and metastatic cells found at SNB had high volume axillary disease identified after completion ANC (P value less than 0.001). In total, only 2% of patients with a benign (B2) SLN core biopsy result had high volume axillary metastases and half of these had either multifocal cancer or invasive lobular carcinoma.

Conclusions
SLN can be readily identified and biopsied in the breast clinic using intradermal microbubbles and CEUS. In patients with primary invasive breast cancer and a normal grey-scale axillary ultrasound, a benign (B2) SLN core biopsy result may be highly predictive of either no metastases or low volume metastatic disease in the ipsilateral axilla. This group of patients is therefore likely to benefit from axillary conservation and in certain cases, it may be appropriate to completely omit a surgical SNB.
Title: Reoperative sentinel lymph node biopsy for ipsilateral breast tumor recurrence: Impact of axillary surgery and radiation therapy on lymphatic drainage patterns

Ayaka Sato1,4, Takehiko Sakai1, Fumiko Moroo1, Kiyomi Kimura1,5, Masahiko Tanabe1,6, Rie Hori2, Futoshi Akiyama3 and Takuji Iwase1. 1Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan; 2Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan; 3The Cancer Institute of Japanese Foundation for Cancer Research, Tokyo, Japan; 4University of Tokyo Hospital, Tokyo, Japan; 5International University of Health and Welfare Mita Hospital, Tokyo, Japan and 6Juntendo University Hospital, Tokyo, Japan.

Body: Background: While sentinel lymph node biopsy (SLNB) is a well-established method for patients with clinically node-negative primary breast cancer, reoperative sentinel lymph node biopsy (re-SLNB) for ipsilateral breast tumor recurrence (IBTR) still remains controversial. The aim of this study was to evaluate the location of reoperative sentinel lymph nodes (re-SLNs) and the factors related to aberrant drainage patterns after breast conserving surgery (BCS).

Methods: Between April 2005 and August 2013, we performed re-SLNB on 132 patients who developed IBTR with no metastatic lymph nodes in preoperative examination. Both injection of radioisotope (Tc-99m phytate) and preoperative lymphoscintigraphy were performed on 97 patients of them, who were eligible for this retrospective study. We divided these patients into two groups according to their previous axillary surgery: 55 patients with just SLNB or no axillary surgery to the group S, and 42 patients with previous axillary lymph node dissection (ALND) to the group D. The patients in the group S were divided into two subgroups: 19 with adjuvant radiation therapy (RT) and 36 without RT. We compared visualization rates of lymph drainage patterns in these groups statistically by using Chi-square test. We evaluated the relationship between previous local treatments and lymphatic drainage patterns.

Results: Number of cases in which lymphatic drainage was visualized were 52 (94.5%) in the group S and 33 (78.6%) in the group D (P < 0.001). Re-SLNs were observed at ipsilateral axilla in 47 patients (90%) in the group S and 19 patients (58%) in the group D (P < 0.001), at internal mammary (IM) in 9 (17%) and 16(49%) (P < 0.01), and at contralateral axilla in 8 (15%) and 5(15%), respectively. Within the group S, lymphatic drainage was visualized in 34 (94.4%) of 36 patients without RT and 18 (94.7%) of 19 patients who had received RT after BCS. Re-SLNs were visualized at ipsilateral axilla in 34 (100%) and 13 (72%) (P < 0.01), at IM in 5 (15%) and 4 (22%), and at contralateral axilla in 1 (3%) and 7 (39%) (P < 0.001).

Re-SLNB was successfully performed in 62 (94%) of 66 patients whose lymphatic drainage was observed at ipsilateral axilla. Metastases for carcinoma in re-SLNs were found in 8 (13%) of them. At IM, re-SLNB was successful in 15 (60%) of 25, and 2 (13%) of them were positive for cancer. At contralateral axilla, re-SLNB was successful in 8 (62%) of 13 while no metastases were found among them.

Conclusion: Previous ALND affected the visualization rates of re-SLNs. In patients after previous ALND, SLN was more likely to be in IM. Adjuvant RT effected a change in lymphatic drainage patterns, but did not affect the visualization rate of re-SLN. At ipsilateral axilla, the rates of successful re-SLNB and metastases at re-SLNs were similar to SLNB for primary breast cancer. Metastasis to SLN of recurrent cancer is one of the most important information for management of IBTR. However, it was very difficult to predict localization of re-SLN because lymphatic drainage patterns could have been affected by previous treatments. Therefore, we recommend re-SLNB using radioisotope with lymphoscintigraphy in surgery for IBTR.
Title: Does axillary lymph node ratio still have a prognostic value in neoadjuvant setting?

Seung Pil Jung¹, Hye Yoon Lee¹, Woo Young Kim¹, Hee Yong Kwak¹, Jae Bok Lee¹, Hoon Yub Kim¹ and Jeoung Won Bae¹.
¹Korea University Hospital, Korea University College of Medicine, Seoul, Korea.

Body: Background: Axillary nodal status is one of the most important prognostic factor in breast cancer. The lymph node ratio has been reported as an independent prognostic factor because the dissected and involved lymph node could be different across the institutions along with surgical and pathologic procedure. Neoadjuvant chemotherapy has been preferred treatment method in locally advanced breast cancer for the purpose of reducing tumor mass in breast and/or axillary area. Neoadjuvant chemotherapy would downstage axillary nodal status and lower total number of excised lymph nodes compared with upfront surgery. Therefore, there has been emerged question whether the axillary nodal status and lymph node ratio following neoadjuvant chemotherapy could accurately predict the prognosis. To answer this question, we evaluated the axillary nodal status and lymph node ratio as a prognostic factor after neoadjuvant chemotherapy.

Methods: One hundred thirty two patients were eligible in this study between 2005 and 2011. The patients underwent breast surgery after 3 or 6 cycles of anthracycline with or without taxane based chemotherapy according to their axillary nodal status. The cut-off range of lymph node ratio were divided to low (≤0.20, n=45), intermediate (2<, ≤0.65, n=25) and high (<0.65, n=6). Clinical and pathologic factors including hormone status, tumor size, lymphovascular invasion and response to chemotherapy were evaluated and survival results were also investigated with nodal status.

Results: Mean age of total patients was 48 years. Mean follow up period was 40 months. The pathologic complete responses were observed 33% in breast, 25% in axillar, 17.4% in both areas, respectively. Tumor subtype was an independent factor for pathologic response rate. With multivariate analysis, clinical tumor size, pathologic nodal status and the presence of lymphovascular invasion were statistically significant to disease free survival in overall cohort. In node negative patients group (n=57), the hormone receptor status and molecular subtype were associated with the disease free survival using multivariate analysis. Whereas, pathologic tumor size, pathologic nodal status and lymph node ratio, especially lower cut-off limit 0.20, were significant risk factor for disease free survival in node positive (n=75) patients.

Conclusion: Neoadjuvant chemotherapy significantly affect axillary nodal status. Traditional nodal staging has been accepted as important prognostic factor. The response to neoadjuvant chemotherapy depends on tumor subtype. In this study, we proved that nodal ratio could be a candidate as prognostic factor in neoadjuvant setting and 0.20 is acceptable lower cut-off value of lymph node ratio.
Title: Application of the Z0011 criteria on Dutch breast cancer patients

Nicole C Verheuvel¹, Vivianne CG Tjan-Heijnen², Adri C Voogd²,³ and Rudi MH Roumen¹,². ¹Máxima Medical Center, Veldhoven, Netherlands; ²Maastricht University, School GROW, Maastricht, Netherlands and ³Dutch National Cancer Registry, Eindhoven, Netherlands.

Body: Background
The American College of Surgeons Oncology Group reported a randomized controlled trial (Z0011-trial) among women with T1-2N0M0 breast cancer treated with breast conserving therapy. It showed that axillary lymph node dissection may be redundant in selected sentinel node positive patients. Though, it raises questions as to the general applicability of these results. Therefore, this study aims to examine the practice changing effect and the clinical relevance of the criteria described in the Z0011 trial, when applied to a Dutch population of patients diagnosed with invasive breast cancer.

Methods
This is a multicenter study including patients with T1-2N0-1M0 invasive breast cancer treated in either of the 10 different hospitals affiliated with the Dutch National Cancer Registry region South in the period between January 2007 and December 2012. All patients underwent a clinical examination, a mammography and sonographic examination of the breast and the ipsilateral axilla. Chi-square analyses or a Fisher’s exact test were used to assess differences in patient and tumor characteristics the Z0011 population and the Dutch cohort. A p-value of ≤0.05 was considered statistically significant.

Results
A total of 11,031 patients had invasive breast cancer, of whom 5368 patients were treated with breast conserving therapy. In 6.8% axillary status was determined by the ultrasound guided lymph node biopsy and in 93.1% axillary metastases were found through the sentinel node procedure after a negative or inconclusive ultrasound. When applying the Z0011 criteria to our study population of node positive patients, 5.7% of all breast cancer patients, equalling 11.8% of patients receiving breast conserving therapy, met the Z0011 criteria.

Conclusion
These results suggest that when applying the Z0011 criteria to all node positive patients, including patients with a positive sentinel node and patients with a positive ultrasound guided lymph node biopsy, only in 5.7% of all invasive breast cancer patients could be spared an ALND and its morbidity. This is a small practice changing effect. Nevertheless, it is worthwhile to consider implementing the findings of Z0011 trial in daily clinical practice.
Contrast enhanced pre-operative axillary staging in breast cancer: A systematic review and meta-analysis

Bauke Anninga¹, Mieke van Hemelrijck¹ and Michael Douek¹. ¹King’s College London, London, United Kingdom.

Background: The current method for identifying axillary metastasis in breast cancer is by performing a sentinel lymph node biopsy (SLNB) procedure. Although highly accurate, this invasive procedure is associated with several adverse events. Additionally, 70% of SLNBs are negative and thus expose many patients to an unnecessary invasive procedure without therapeutic benefit. Contrast enhanced imaging alternatives have the potential to replace SLNB. Several contrast agents have been evaluated of which gadolinium (Gd) and superparamagnetic iron oxide (SPIO) are most frequently documented. We conducted a systematic review and meta-analysis of the accuracy of contrast enhanced magnetic resonance imaging (MRI) techniques for pre-operative axillary staging in early stage, newly diagnosed breast cancer patients.

Materials and methods: We systematically searched the MEDLINE, Cochrane and EMBASE databases for prospective studies that evaluated MRI with contrast for axillary lymph node metastasis detection. Pooled sensitivity and specificity of contrast enhanced MRI were extracted from every study using histological diagnosis as the comparative gold standard. Per patient and per node analyses were undertaken. Statistical analyses were performed using OpenMetaAnalyst.

Results: Searching the databases resulted in a total of 211 abstracts of which 17 were considered for inclusion in the meta-analysis. Quantitative analyses on 14 full-texts and 1 abstract including a total of 493 (n = 11 studies) patients and 1373 (n = 7 studies) lymph nodes were performed. Six studies described the use of SPIO, five described the use of Gd, one study used gadopentetate dimeglumine and one gadofosveset. Overall weighted sensitivity and specificity of contrast enhanced MRI were 84% (95% CI: 77-89%) and 83% (95% CI: 70-91%) respectively, per patient. The sensitivity and specificity for detecting metastases on a lymph node basis were 80% (95% CI: 73-85%) and 96% (95% CI: 94-98%), respectively. In the studies evaluating SPIO enhancement, per patient sensitivity and specificity were 86% (95% CI: 75-93%) and 89% (95% CI: 82-94%), respectively. For studies evaluating Gd enhancement per patient sensitivity and specificity were 84% (95% CI: 74-93%) and 80% (95% CI: 60-92%), respectively.

Conclusion: Contrast enhanced MRI has the highest sensitivity and specificity when SPIO is used. Overall, it is less sensitive but more specific on a per node basis compared to a per patient analysis. Research is needed to optimise the field of view for nodal imaging in order to increase sensitivity and specificity for the detection of nodal metastases.
Title: Prospective evaluation of the reliability of the combined use of two models to predict non-sentinel lymph node status in breast cancer patients with metastatic sentinel lymph nodes: The MSKCC nomogram and the Tenon score – PHRC-NOTEGS study

Roman Rouzier\(^1\), Catherine Uzan\(^2\), Alexandra Rousseau\(^3\), Eugenie Guillot\(^1\), Sonia Zilberman\(^3\), Charles Meyer\(^4\), Pablo Estevez\(^1\), Pierre-François Dupre\(^5\), David Kere\(^6\), Virginie Doridot\(^7\), Gauthier D'halluin\(^8\), Xavier Fritel\(^9\), Nicolas Pouget\(^10\), Chafika Mazouni\(^2\), Tabassome Simon\(^3\) and Charles Coutant\(^10\). \(^1\)Institut Curie, Paris, France; \(^2\)Gustave Roussy, Villejuif, France; \(^3\)APHP, Paris, France; \(^4\)Hôpitaux Civils de Colmar, Colmar, France; \(^5\)CHU Brest, Brest, France; \(^6\)Institut Jean Godinot, Reims, France; \(^7\)Centre Médical République, Clermont-Ferrand, France; \(^8\)Centre Clinical Soyaux, Soyaux, France; \(^9\)CHU Poitiers, Poitiers, France and \(^10\)Centre Georges François Leclerc, Dijon, France.

Body: Background: Several mathematical models have been developed to predict non-SN status in patients with breast cancer with SN metastasis. The Memorial Sloan-Kettering Cancer Center nomogram and Tenon score outperform other methods in academic studies but their exportability at multiple geographic locations and practice settings has never been reported. The purpose of this study was to prospectively evaluate the combined use of the MSKCC nomogram (Memorial Sloan-Kettering Cancer Center) and Tenon score to select, in patients with metastatic sentinel lymph node (SN), those at low risk of metastatic non-SN in whom additional axillary lymph node dissection (ALND) could be avoided.

Material and methods: From January 2011 to July 2012, data on 3157 patients with breast cancer from 65 institutions (university affiliated, general, regional hospital, nonprofit private hospital and private practice) were prospectively recorded (NCT01509963). Selection criteria were patients aged over 18 years old with untreated invasive T1-2 breast cancer with an indication of SN procedure. The primary outcome measure was the false negative rate in patients with both a \(\leq 10\%\) probability of metastatic non-SN with the MSKCC nomogram and a Tenon score \(\leq 3.5\) (i.e. low risk): proportion of patients with metastatic non-SN in whom additional axillary lymph node dissection (ALND) was not mandatory. The hypothesis was a 5%±5% rate in this group of patients. Other patients were considered at high risk. Because of the results of the Z011 and IBCSG 23-01 trials, additional ALND was not mandatory in case of metastatic SN.

Results: Among the 2936 patients, at least one SN was metastatic (isolated tumor cells, micro- or macrometastasis) in 696 patients (23.7%). Among them, 178 did not have completion ALND. Among patients with completion ALND (n=518, 74.4%), 67 (13%), 437 (84%) and 14 (3%) patients were at low, high and undetermined combined risk while 47.5% were at low risk in patients without completion ALND (p<.001). This study did not meet its primary objective as the false negative rate in patients with low risk was 16.4% (11/67) [95% confidence interval: 8.5%-27.5%]. The false negative rate was significantly higher in patients in the high risk group: 33.9% (148/437) [95% confidence interval: 29.6%-38.4%] had non-SN metastasis (p=.004).

Analyzed individually, Tenon score and MSKCC nomogram had complementary performances (number of patients at low risk: 35.3% and 18.5%, false negative rates: 21.9% and 17%, concordance index: 0.63 and 0.65, respectively).

Conclusion: In this controlled prospective trial, metastatic SN patients with both a \(\leq 10\%\) probability of metastatic non-SN with the MSKCC nomogram and a Tenon score \(\leq 3.5\) had completion axillary dissection in 47% of cases: in these patients, the false negative rate was statistically over 5% and did not reach the primary endpoint. Further evaluation is warranted to determine the outcome of patients with and without axillary dissection.
Title: Impact of the ASOCOG Z0011 trial on a multi-institutional mixed practice setting

Swapnil D Kachare¹, Nasreen A Vohra¹, Kathryn M Verbanac¹, Timothy L Fitzgerald¹, Emmanuel E Zervos¹ and Jan H Wong¹.
¹East Carolina University, Greenville, NC.

Body: Background
The ASOCOG Z0011 trial is widely considered to be practice changing, but reports to date on the adoption of Z0011 are largely confined to tertiary academic institutions with breast cancer surgical specialty services. The aim of this study was to assess the impact of Z0011 on the care of breast cancer patients in a mixed academic/ non-academic practice setting.

Methods
All patients who underwent surgical treatment for breast cancer in the Vidant Healthcare System, a multi-county network, between the years January 1, 2009 and September 20, 2013 were identified. Patients with Stage IV disease and ductal carcinoma in situ were excluded.

Results
One thousand six hundred four patients met initial inclusion criteria, 661 in the pre-Z0011 period and 973 in the post-Z0011 period. The majority of patients were female (99%) and Caucasian (65%). Infiltrating ductal cancer (67%) was the most common tumor type. Tumors on average were 23mm in size with the majority being ER (74%), PR (63%) positive and Her2 (82%) negative. Most patients had node negative disease (73%). Table 1 summarizes the characteristics of the pre- and post-Z0011 study populations.

A total of 142 patients met Z0011 criteria, with T1-2 disease, underwent partial mastectomy and had a positive SNB. There were a similar number of patients who met Z0011 criteria in the pre- (n=63) and post-Z0011 (n=79) periods, p>0.05. In the post-Z0011 period, patients were more likely to undergo SNB alone (56 vs. 19%, p<0.001). Post-Z0011 the decrease in ALND was in those who had immediate ALND (34% vs. 71%), with no substantive change in the delayed group (10.1 vs. 9.5%), p<0.001. Patient who underwent SNB alone had smaller tumors (22 vs. 32mm, p<0.001), but similar histologic subtypes (p=0.60) and receptor status (p≥0.15) as compared to patients who underwent SNB with ALND. Over the entire study period patients in an academic practice
were less likely to undergo SNB alone (31 vs. 43%). In the post-Z0011 period, patients cared for in an academic practice had an increase in SNB alone from year 1 (2012) to year 2 (2013) (40% to 57%), while the non-academic practices had a decrease in SNB alone from year 1 to year 2, (63% to 56%).

**Conclusion**

In this mixed practice setting there was an overall decrease in ALND in T1/T2 patients with low metastatic axillary burden following publication of Z0011. Immediately post-Z0011 the non-academic practices more rapidly adopted SNB alone, however these differences were no longer apparent two years following Z0011. Continued longitudinal studies will further assess the variability in the incorporation of Z0011 among various surgical practices.
Title: Vascularized lymph node transfer for the treatment of upper extremity lymphedema in breast cancer

Richard D Klein1, Kristine Secrest1, Kenneth R Lee1 and Jeffrey Feiner1. 1UF Health Cancer Center at Orlando Health, Orlando, FL.

Body: Background: It is estimated that approximately 6.8 million people suffer with lymphedema in the United States. These patients can experience pain, heaviness, restricted motion and recurring infections all leading to poor quality of life. Vascularized lymphnode transfer (VLNT) not only offers the possibility of reduction of symptoms but also significant improvement in quality of life.

Methods: We evaluated the efficacy of VLNT in upper extremity lymphedema in breast cancer patients. MRI lymphangiogram was utilized to determine extent of lymphedema, area of blockage and transition zones. Pre surgical evaluation consisted of circumferential and volumetric measurements, pain, heaviness and quality of life. Eligible patients underwent VLNT with placement of transferred lymphnodes to the axilla or upper arm. Reassessment occurred at 1, 3, 6, 9, 12 and 18 months after surgery.

Results: Preliminary results showed arm volumes decreased by 22% at 3 months and 52% at 6 months and almost 60% at 9 months. Quality of life scores improved from 4.9 at preop to 7.4 at 3 months and 8.6 at 6 months. Pain and heaviness scores improved from 4.22 and 4.94 at preop to 0.14 and 1 at 3 months and 1 and 1.5 at 6 months.

Conclusions: Vascularized lymph node transfer has transformed the outlook for patients afflicted with limb lymphedema after breast cancer therapy. It has led to limb volume reduction and improvement in pain and heaviness. Additionally, quality of life has improved for all patients.
Pre-operative axillary staging results in over-treatment in some breast cancer patients

Andrew Pieri¹, Henry Cain² and Sebastian Aspinall³. ¹Wansbeck Hospital, Ashington, Northumbria, United Kingdom; ²Royal Victoria Infirmary, Newcastle Upon Tyne, Tyne & Wear, United Kingdom and ³University Hospital of North Tyneside, North Shields, Tyne & Wear, United Kingdom.

Body: Introduction
Following a diagnosis of breast cancer, pre-operative ultrasound staging of the axilla is recommended. Patients found to have metastatic disease on biopsy or FNA can proceed directly to axillary clearance (ALNC) at the time of their breast tumour excision. However, although ultrasound staging is a sensitive test to detect axillary disease, it does not differentiate between low and high volume nodal metastasis. Recent evidence suggests that, in selected patients with low volume axillary disease following SLNB, completion ALNC may be safely omitted. This has been reflected in the recently updated ASCO guidelines. In light of this current trend towards axillary conservation, some patients undergoing ALNC after positive axillary staging may be over-treated. The aims of this study is to establish the nodal burden of patients undergoing ALNC following positive axillary staging and to compare the nodal burden of those patients with those undergoing completion ALNC after a positive SLNB.

Methods
Data was collected prospectively over 12 months from nine hospitals within the North of England Cancer Network. Age, tumour characteristics, breast operation, axillary staging results, axillary operation(s) and nodal results were recorded.

Results
A total of 1010 patients with breast cancer underwent pre-operative axillary staging. 215 patients (21%) had an ALNC. Of these, 115 (53%) cases underwent a primary ALNC after positive staging. The remaining 100 (47%) patients had a completion ALNC following a positive SLNB. The nodal burden for patients undergoing ALNC is shown in the table below:

Analysis of the data revealed that tumour size was a significant predictor of low volume axillary disease (i.e. <3 nodes positive) [p=0.02, Mann-Whitney test].

Conclusion
In this study, 46% of patients undergoing ALNC after positive staging had low volume disease (2 or less positive nodes). In the context of recent evidence if these patients had undergone a SLNB following the positive pre-operative staging they may have avoided a completion ALNC.

This study demonstrates tumour size to be a significant predictor of low volume axillary disease and thus may be an important factor to consider alongside pre-operative staging when selecting patients who may be better managed by a SLNB rather than proceeding directly to ALNC.
Title: Noninvasive assessment of axillary lymph node metastases in breast cancer using EpCAM antibody

Shu Wang¹, Jiajia Guo², Liulu Zhang³ and Houpu Yang⁴. ¹Peking University People's Hospital Breast Center, Beijing, China; ²Peking University People's Hospital Breast Center, Beijing, China; ³Peking University People's Hospital Breast Center and ⁴Peking University People's Hospital Breast Center.

Body: Background: Axillary lymph node metastasis is one of the most important prognostic determinants for patients with breast cancer. It’s a big progress from axillary lymph node dissection (ALND) to sentinel lymph node biopsy (SLNB), however, SLNB also has some limitations, including the detection failure rate, false negative rate, tracer allergies et al. Since about 70% of early breast cancer patients have negative SLNs, surgery maybe overtreatment for these patients and noninvasive assessment of axillary staging seems to be a better choice. It’s not easy to detect and mapping metastasis lymph nodes in vivo non-invasively because we don’t have specific cancer markers, but what we know is that most breast cancer cells come from epithelial origin and should have epithelial markers, and this kind of markers should not show up in lymph system. EpCam is a surface epithelial marker and expressed in 80-100% breast cancer patients. The aim of this study was to evaluate the value of EpCAM antibody in detecting breast cancer lymph node metastases non-invasively.

Methods: VX2 rabbit model which is an epithelial tumor model with lymph node metastasis was used in this experiment. Anti-EpCAM was labeled with a near infra-red (NIR) fluorescence imaging agent Cy7 and selected as metastasis tracer. New Zealand white rabbits were assigned to study group and control group at random. Twelve rabbits in the study group received VX2 tumor injection to bilateral mammary glands and 12 rabbits in the control group were tumor free. Twenty four cases of axillary lymph nodes metastasis were investigated in each group because of bilateral experiments. Anti-EpCAM/Cy7 was subcutaneously injected around the tumors in study group or in mammary gland in control group at a dosage of 0.1ml (10umol/L). After 30 hours of screening by a NIR fluorescence detection machine, all the axillary lymph nodes in both groups were removed for pathological examination and the fluorescence status of each node was recorded.

Result: The fluorescence signal could be detected 2 hours after injection in 24 cases in the control group and 23 cases in the study group. Thirty hours later, fluorescence disappeared in all cases in the control group and all the lymph nodes resected were pathological negative. While in study group, fluorescence signal could be detected continuously in 14 cases and 13 were proven to be pathological metastasis. The case failed to have fluorescence image from the beginning finally proved to be vascular invasion and cancerous node formation. The sensitivity, specificity rate of anti-EpCAM/Cy7 to detect axillary lymph node metastasis was 92.8% (13/14) and 90.0% (9/10).

Conclusion: The NIR dye labeled EpCAM antibody (anti-EpCAM/Cy7) has a high accuracy in evaluating the axillary lymph node status of breast cancer in the animal experiment. Our tiny preclinical experiment showed the value of using EpCAM antibody as a new method for noninvasive lymph node evaluation for breast cancer and potentially extended in a lot of other epithelial originated cancers.
Title: Role of 18 FDG PET/CT in axillary staging in early breast cancer

Cristina Noblia¹, Eugenia Azar¹, Dolores Mansilla¹, Amilcar Osorio², Eduardo Armanasco¹, Diana Montoya¹, Martin Ipiña¹, Gaston Berman¹, Eduardo Gonzalez¹, Christian Gonzalez², Gabriel Bruno², Patricia Parma², Carla Pulero¹ and Ana Alvarez¹. ¹Angel H. Roffo Institute, Buenos Aires, Caba, Argentina and ²Nuclear Diagnostic Center Foundation, Buenos Aires, Caba, Argentina.

Body: OBJECTIVE To evaluate the 18F-FDG PET/CT capacity for the detection of axillary metastases and compare results with sentinel lymph node biopsy (SLNB). MATERIAL AND METHODS: 99 female patients with clinical T1T2N0 breast cancer were included. Patients with recent breast or axillary surgery, T3T4 disease, ductal carcinoma in situ, inflammatory carcinoma, uncontrolled diabetes mellitus and pregnant or lactation patients were excluded. Pre-operative FDG PET-CT was performed 15 days before surgery, SLNB took place with the combined method (radioisotopes and patent blue). Pearson and Spearman correlation test were used to evaluate association of main variables with a significance level (p) of 0.05. RESULTS: Breast PET-CT results: 80 positive PET/CT. Negative PET/CT in 19 patients (4 invasive lobular carcinoma, 7 tumors <7mm) Sensitivity 81%, specificity 100%. 97 patients were operated (2 were stage IV with no surgery criteria). We found significant correlation of the FDG tumor uptake (SUV) with tumor size (p<0.0001), histological grade (p<0.009), nuclear grade (p<0.001), mitotic grade (p<0.007) and Ki 67 (p<0.0001). In all cases the correlation was positive. There was no correlation with hormonal receptors rate. Axillary PET CT results: positive PET/CT in 16 patients (16%). Of this 6 SNLB were negative (FPR= 9%). Specificity 91%, PET/CT were negative in 81 patients (84%), 17 had axillary metastases(5 micrometastases, 2 isolated tumor cells and 2 lobular carcinoma). Sensitivity:37%. FNR=63%. Correlation of histopathological axillary metastases was positive with breast tumor SUV (P<0.002) and tumor size (p<0.01), but was not significant with histological, nuclear and mitotic grade, Ki 67, hormonal receptor rate and molecular subtype CONCLUSION: 1- PET/CT does not provide benefits for axillary staging in initial stages due to its low spatial resolution (6-8 mm) 2 – A negative axillary by PET/CT does not replace the sentinel node technique. 3 – We can suspect the presence of axillary metastases when there is an intense FDG uptake in the breast tumor.
Title: Total tumoral load as a prediction tool of non-sentinel node metastases in patients with early breast cancer and positive sentinel lymph node assessed by OSNA

Martin Espinosa-Bravo¹, Francesc Pérez-Ceresuela¹, Sebastian Diaz-Botero¹, Vicente Peg² and Isabel T Rubio¹. ¹Breast Surgical Unit, Breast Cancer Center, Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Barcelona, Spain and ²Hospital Universitari Vall d'Hebron. Universitat Autònoma de Barcelona, Barcelona, Spain.

Body: Background: Total tumoral load (TTL) in the sentinel lymph nodes (SLN) assessed by the OSNA assay is a new variable that is able to predict the likelihood of more axillary metastasis. Compared with the number of positive SLNs, the TTL is independent of the number of metastatic SLNs and a better predictor of further nodal metastasis. Although establishing specific cutoff-points of the TTL can be questionable because they may change in the future and increasingly become more patient specific, we have seen that TTL <15,000 could be a good cut off by its high negative predictive value (NPV). Changes in practice have been occurred after the ACOSOG Z0011 trial and nowadays, patients with ≤ 2 positive SLNs may spare an axillary lymph node dissection (ALND) with no impact on the oncological outcome. In the Z0011, 27% of patients had additional non-SLN metastasis in the cALND. The objective of this study was to compare two methods of SLN metastatic burden, the TTL and the number of positive SLNs, for predicting non-SLN metastasis in patients with positive SLNs by OSNA.

Methods: This is a retrospective cohort study of 145 consecutive patients with cT1-T2 invasive breast cancer with ultrasonographically node-negative treated between April 2010 to April 2013, where there is at least one positive SLN assessed by OSNA. We design a prediction tool based on the TTL results determined by OSNA to calculate the likelihood of not finding more positive non-SLN (http://www.vhebron.net/es/calculadora-risc-metastasi-2). Our group have demonstrated that TTL=15,000 could be a good cut off by its high NPV and sensitivity, 85.5% and 76.7%, respectively.

Results: A total 325 SLNs were removed with a mean of 2.24. The type of SLN metastasis were macrometastasis in 85 patients (58.6%) and micrometastasis in 60 patients (41.4%). When considering patients with number of positive SLNs, of 109 patients with ≤2 positives SLNs and an cALND, 17 patients (22%) had non-SLN metastasis; and of 5 patients with ≥3 SLN, four (80%) had non-SLN metastasis. Taking the TTL results, of 51 patients with TTL <15,000 copies/µL with cALND (90.2% with one positive SLN), 7 patients (14%) had non-SLN metastasis, were a media of 2.2 extra non-SLN metastasis. Of 55 patients with TTL ≥15,000 copies/µL (with 1 or 2 positives SLNs) with cALND, 20 patients (36%) had non-SLN metastasis and there were a media of 2.5 non-SLN metastasis (range 1-8). Of 34 patients (62%) with one positive SLN with TTL ≥15,000 copies/µL, 12 patients (35%) had non-SLN metastasis; and of 21 patients with two positive SLN with TTL ≥15,000 copies/µL, eight patients (38%) had non-SLN metastasis.

Conclusion: The total tumor load obtained by OSNA predicts non-SLN metastasis independent of the number of positive SLNs. The assess of the TTL in our cohort of patients show that patients with one or two positives SLNs with high TTL had high likelihood of non-SLN metastasis greater than 27% of Z0011 criteria. Prospective studies are needed to determine the clinical impact of this variable in patients outcome in the management of patients with SLN assessed by OSNA.
**Title:** Preoperative axillary imaging with ultrasonography: Among the breast cancer patients with lymph node metastases, can we identify the patients who may omit axillary dissection?

Naoto Kondo\(^1\), Takashi Fujita\(^1\), Masataka Sawaki\(^1\), Masaya Hattori\(^1\), Akiyo Yoshimura\(^1\), Mari Ichikawa\(^1\), Junko Ishiguro\(^1\), Yayoi Adachi\(^1\), Haruru Kotani\(^1\), Tomoka Hisada\(^1\) and Hiroji Iwata\(^1\). \(^1\)Aichi Cancer Center Hospital, Nagoya, Aichi, Japan.

**Body:**

(\textit{Introduction}) ACOSOG Z11 and EORTC AMAROS showing little benefit to axillary dissection (ALND) for early stage breast cancers with limited nodal disease have led us to questioning the value of preoperative axillary imaging. It may not result in a benefit to the patients to perform ALND by diagnosing a few or small axillary lymph node (ALN) metastases preoperatively.

(\textit{Aim}) A purpose of this study is to determining the association between diagnostic method and metastatic number of ALN metastases, and to find the patients who can omit ALND safely even if with ALN metastases.

(\textit{Methods}) A database of consecutive primary breast cancer patients who underwent complete ALND at our institution in 2008-2011 was analyzed. After we excluded patients treated with neoadjuvant systemic therapy, a total of 390 patients were included. By diagnostic methods of ALN metastases, we classified them in four groups as follows. Group A (n=41) : suspicious ALNs on axillary ultrasound (AUS) and ultrasound-guided fine needle aspiration cytology (FNAC) positive, Group B (n=47) : only one abnormal ALN on AUS +/- FNAC, Group C(n=53) : multiple abnormal ALNs +/- FNAC, Group D (n=249) : negative ALNs on AUS but SLNB positive.

(\textit{Results}) The median number (range) of ALN metastases were 3(1-22) in GropuA, 2(0-12) in Group B, 7(1-37) in Group C, 1(1-17) in Group D. There were significant differences in number of metastases between Group A, B, C and Group D (\(p=.02\), \(p=.01\), \(p=.002\)). Patients with 3 or less positive ALNs were 24.5% (13/53) in Group C, whereas 61.0% (25/41) in Group A and 68.1% (32/47) in Group B (\(p=.04\), \(p=.02\)). We next evaluated the influence of patient- and tumour-related variables on the number of positive ALNs in Group A/B. Factors such as age, tumour size (<20mm vs >20mm), ER status (positive vs negative), HER2 status (positive vs negative), nuclear grade (1/2 vs 3), menstruation status (pre vs post menopausal) were examined. However there were no significant differences in all factors between the patients with 4 or more ALN metastases and patients with 3 or less ALN metastases. As a result of multivariable analysis, relative risk (95%CI, \(p\)-value) of age was 0.92 (0.546-1.347, 0.84), tumour size : 0.82 (0.511-1.418, 0.76), ER status : 1.06 (0.873-1.821, 0.76), HER2 status : 1.17 (0.853-2.390, 0.28), nuclear grade : 0.43 (0.420-1.22, 0.34), menstruation status : 0.85 (0.538-1.693, 0.89). (\textit{Conclusion}) In our contemporary series, patients diagnosed as ALN metastases preoperatively have significantly more involved nodes compared to SLNB positive patients regardless of the diagnostic method, suggesting that such patients should proceed to ALND. Preoperative axillary imaging are useful to identify node-positive breast cancer patients requiring ALND.
Title: Long-term follow-up of the node-negative breast cancer patients before treatment evaluated with sentinel node biopsy alone following neoadjuvant chemotherapy

Hiroko Nogi, Ken Uchida, Makiko Kamio, Kumiko Kato, Yasuo Toriumi and Hiroshi Takeyama. Jikei University School of Medicine, Tokyo, Minato-ku, Japan.

Body: BACKGROUND Sentinel node biopsy (SNB) for the node negative breast cancer is standard treatment as an accurate assessment of axillary lymph node status. The use of neoadjuvant chemotherapy (NAC) has increased during the past several years. At present, the use of SNB following NAC is controversial. Proponents of SNB after NAC prefer a single surgical procedure with potential for fewer axillary dissections.

OBJECTIVE Our objective was to examine SNB evaluation alone following NAC in patients with clinically node-negative breast cancer before treatment and to evaluate the axillary lymph node recurrence for patients undergoing NAC versus patients undergoing surgery first.

METHODS A total of 1176 patients with clinically node negative breast cancer underwent SNB from 2007 to 2013. Clinicopathologic and survival data were reviewed and comparisons made between patients receiving NAC and those undergoing surgery first. Lymphatic mapping was performed with both radioactive colloid and blue dye. Patients with negative SN for metastasis were followed without axillary lymph node dissection (ALND). Patients with metastases to a SN underwent ALND.

RESULTS Of the patients, 180 (15.3%) underwent SNB following NAC and 996 (84.7%) underwent surgery first. SN identification rates were 98.3% in the NAC group and 98.9% in the surgery first group. 152 (84.4%) patients in the NAC group and 877 patients (88.1%) had negative SNs. At median follow-up of 49.2 months, 1 patient (0.007%) in the NAC group and 3 patients (0.003%) in surgery first group had axillary lymph node recurrences. There were not any significant differences between the NAC group and the surgery first group.

CONCLUSION The SNB following NAC in patients with node-negative breast cancer has a low axillary recurrence rate and could be acceptable.

**Title:** The ratio and size of positive sentinel lymph nodes predicts the involvement of non-sentinel lymph nodes following completion axillary lymph node dissection

Rajiv V Dave¹, Muhhamed N Chauhan¹, Maria Ghaus¹, Sana Ahmed¹, Shiv Shapra¹, Joshua Marriott¹, Craig Sayers¹, Zbigniew Kryjak¹ and Deedar Ali¹. ¹Pinderfields Hospital, Wakefield, West Yorkshire, United Kingdom.

**Body:** Background: The role of Completion Axillary Lymph Node Dissection (CALND) following positive Sentinel Lymph Node Biopsy (SLNB) is being actively debated. The involvement of our unit in the POSNOC trial (which has a no-treatment arm), has prompted a review of our unit’s CALND results, in order to examine predictors of involvement of non-sentinel lymph nodes (n-SLN), to better inform our patients during recruitment.

Methods: We retrospectively analysed our experience of SLNB between July 2008 to 2013. A total of 1152 breast cancer patients underwent SLNB based on lymphoscintigraphy, intraoperative gamma probe detection, and blue dye mapping using 99mTc-nanocolloid and Patent Blue V injected peri-areola.

Results: Out of 1152 SLN biopsies performed, 224 were positive for metastatic disease. 203 patients were anaesthetically capable of progressing to CALND. On univariate analysis, involved n-SLN on CALND could not be predicted by age (<50 years; 16/77 vs ≥50 years; 93/125, p=0.272), size of tumour (<50mm; 44/193 and ≥50mm; 4/10, p=0.188), procedure (mastectomy; 24/93, WLE; 24/106, p=0.444), lymphovascular invasion (22/97 vs 26/106, p=0.812), number of positive SLN (≤2; 45/196, >2; 3/7, p=0.213), receptor status; ER (negative; 3/13, positive 45/187, p=0.619), PR (negative; 6/28, positive 41/169, p=0.478), Her2 (negative; 43/175, positive 5/25, p=0.414), triple negative (2/8 vs 46/192, p=0.612). There was a trend toward higher incidence of positive n-SLN with increasing grade (G0-2; 28/139 vs G3; 20/64, p=0.062) and extracapsular spread (14/41 vs 32/149, p=0.073), but these did not reach statistical significance. Positive n-SLN on CALND was however predicted by macrometastases in SLN (macrometastases; 39/141 vs micrometastases; 9/62, p=0.029) and ratio of positive nodes (<0.5; 18/109 vs ≥0.5; 30/94, p=0.008). There were 4/224 recurrences (3 distant metastases and 1 loco-regional), which were not predicted by any of the clinicopathological variables investigated. 3 patients who recurred only had one positive node on SLNB.

Conclusion
In our series of more than 200 SLNB, a ratio of >0.5 positive SLN yield and presence of macrometastases in positive SLN, were associated with positive n-SLN on CALND.
Title: Management of the axilla in breast cancer patients: Do we over treat patients with preoperative diagnosis of nodal metastasis?

Ioannis Michalakis¹, Jaroslaw Krupa¹ and Louisa Dunk². ¹Glenfield Hospital, Leicester, United Kingdom and ²Glenfield Hospital, UHL Trust, Leicester, United Kingdom.

Body: Introduction: Axillary lymph node status is the most significant single prognostic factor in breast cancer patients. Axillary ultrasound scan (AUS) followed by fine needle aspiration (FNA) is the gold standard modality in preoperative staging of the axilla and spares the patient a possible second operation. Sentinel lymph node biopsy (SLNB) accurately stages the axilla with low axillary recurrence rates and reduced morbidity. Increasing evidence suggests that surgical removal of the axillary lymph nodes (completion ALND) in early breast cancer with limited nodal disease yields no advantage in terms of either overall or disease-free survival. The purpose of this audit is to identify possible changes in management of the axilla in patients having preoperative diagnosis of nodal metastasis.

Methods: We reviewed the available data from breast cancer patients that had positive FNA after AUS (441) or positive nodes at a SLNB (324) in our unit from 2007 to 2013.

Results: 410 of the 441 (93%) patients with a preoperative diagnosis of nodal metastasis received completion ALND. 147 of the 410 (36%) patients had neoadjuvant chemotherapy and of these 34 (23%) had complete pathological response at the axilla. 101 of the 263 (38%) patients who did not receive neoadjuvant chemotherapy had 1 or 2 nodes involved and also had a T1 or T2 tumour.

Conclusions: Breast cancer patients with a preoperative diagnosis of nodal metastasis are treated in a different way than the patients with positive SLNB. Axillary treatment may be improved if we could identify patients with a preoperative diagnosis of nodal metastasis that fulfil the criteria of the Z11 trial and so potentially save patients unnecessary axillary surgery.
Internal mammary sentinel lymph node biopsy with modified injection technique: High visualization rate and accurate staging

Peng-Fei Qiu¹, Bin-bin Cong¹, Rong-Rong Zhao¹, Yan-Bing Liu¹, Guo-Ren Yang¹, Peng Chen¹ and Yong-Sheng Wang¹.
¹Shandong Cancer Hospital&Institute, Jinan, Shandong, China.

Background: Although the 2009 AJCC incorporated the internal mammary sentinel lymph node biopsy (IM-SLNB) concept, there has been little change in surgical practice patterns due to the low internal mammary sentinel lymph nodes (IM-SLNs) visualization rate (VR) with the traditional radiotracer injection technique (average 13%, 0-37%). In this study, various injection techniques were evaluated in terms of the IM-SLNs VR in clinically axilla lymph nodes (ALNs) negative patients, and the impact of IM-SLNB on the diagnostic and prognostic value were analyzed both in clinically ALNs negative (NCT01642511) and positive patients (NCT01668914).

Methods: 340 patients with T1-2 invasive breast cancer were enrolled. Clinically ALNs negative patients (n=293) were divided into 3 groups according to the study period and radiotracer injection technique. Group A: traditional technique (peritumoral intraparenchymal injection) for the initial 58 cases; Group B: periareolar intraparenchymal injection under the ultrasonography guidance in the latter 235 cases, the injection sites were chosen at the 6 and 12 o’clock positions 0.5-1.0 cm from areola (about 2.0-4.0 cm from the nipple). Group B was then separated into 2 groups according to the radiotracer injection volume: Group B1, low volume (<0.5ml/point, n=41); Group B2, high volume (≥0.5ml/point, n=194). Clinically ALNs positive patients (n=47) were managed as group B2. IM-SLNB was performed for patients with IM-SLNs visualized on preoperative lymphoscintigraphy and/or detected by intraoperative gamma probe.

Results: Clinically ALNs-negative: The IM-SLNs VR was significantly higher by lymphoscintigraphy in Group B than that in Group A (63.0% vs. 13.8%, P<0.001), while the axillary VR was similar in these two groups (84.3% vs. 77.6%, P=0.227). The VR of sentinel lymph nodes was improved by the intraoperative gamma probe compared to lymphoscintigraphy: Group A (axilla: 77.6%→98.3%, P=0.001; internal mammary: 13.8%→15.5%, P=0.794) and Group B (axilla: 84.3%→98.7%, P<0.001; internal mammary: 63.0%→70.6%, P=0.078). Group B2 was found to have the highest IM-SLNs VR (74.2% vs. 53.7% Group B1, P=0.009). The successful rate of IM-SLNB was 95.8%, and arrived 100% after 20 cases learning curve. In the patients who underwent IM-SLNB, the IM-SLNs metastases rate was 8.7%, systemic treatment was changed only in 4.3%; however, radiotherapy treatment was changed in 8.7%. For the patients with upper inner quadrant tumor, systemic and radiotherapy treatment was changed in 8.8% and 20.6%.

Clinically ALNs-positive: IM-SLNB was performed in all patients with drainage to IM-SLNs (VR: 70.2%, 33/47); the successful rate was 100% (33/33). The IM-SLNs was positive in 21.2% patients, and the internal mammary radiotherapy could be guided with this IM-SLNB results.

Conclusions: The modified injection technique (periareolar intraparenchymal, high volume and ultrasonography guidance) significantly improved the IM-SLNs VR, making the routine IM-SLNB possible in daily practice. IM-SLNB could provide individual staging, prognosis, and decision-making of the internal mammary radiotherapy for breast cancer patients, especially in positive ALNs and high-risk negative ALNs patients.
Title: Validation of diagnostic procedure for metastatic lymph nodes in breast cancer using a semi-dry dot-blot method and novel anti-cytokeratin 18+19 antibodies

Ryota Otsubo1, Masahiro Oikawa1, Hiroshi Hirakawa2, Hiroshi Yano1 and Takeshi Nagayasu1. 1Nagasaki University Hospital, Nagasaki, Japan and 2Chiba Aiyuuukai Memorial Hospital, Chiba, Japan.

Body: Introduction: Sentinel lymph node (SLN) biopsy is a common diagnostic procedure for breast cancer. However, because of a shortage of pathology specialists in Japan and discordance between intra-operative and final pathological diagnoses of SLN metastasis, new diagnostic modalities are desperately required. We previously reported a novel method of detecting metastasis in SLNs by a semi-dry dot-blot (SDB) method with 93.3% sensitivity, 96.9% specificity and 96.6% accuracy. Here, we evaluated the efficacy of the SDB method using novel anti-cytokeratin (CK) 18+19 antibodies to diagnose lymph node metastases in breast cancer.

Materials and methods: We obtained 73 lymph nodes dissected from 43 patients with breast cancer from July 2013 to May 2014 at Nagasaki University Hospital and the Japanese Red Cross Nagasaki Genbaku Hospital, including 55 sentinel lymph nodes and 18 dissected axillary lymph nodes, which were sliced at 2-mm intervals and washed with phosphate-buffered saline. This lavage fluid was used to diagnose lymph node metastasis by the SDB method; whereas the washed lymph nodes were blindly diagnosed by pathologists using with hematoxylin and eosin (H&E) stain. Suspended cells in the lavage fluid were centrifuged; the cell pellet was lysed with lysis buffer to extract protein, which was then challenged and visualized with anti-cytokeratin 18 and 19 antibodies, each at 1 µg/ml and 0.1 µg/ml to distinguish between micrometastases or isolated tumor cells (ITC) and macrometastases; and with chromogen on a dot-blot membrane. Diagnoses based on the SDB method were compared with their H&E counterparts. When the SDB method and H&E-based examinations did not agree, we examined specimens immunohistochemically with anti-cytokeratin18+19 antibodies.

Results: Of the 73 lymph nodes, 25 were assessed as positive and 48 as negative by the permanent pathological examination with H&E. The SDB method made correct diagnoses in all positive cases and 42 of the 48 pathologically negative cases. We found four micrometastases and one ITC in the positive cases, which were difficult to diagnose as positive at the lower antibody concentration, but were clearly positive at the higher concentration. When the 6 discrepant cases were examined immunohistochemically, we found two cases of ITC and one of micrometastasis. Sensitivity, specificity and accuracy of the SDB method in detecting cancer cells were 100% (95% confidence interval [95% CI]: 100–100%), 93.8% (95% CI: 86–101%) and 95.9% (95% CI: 91–100%), respectively.

Conclusions: The SDB method using anti-CK18+19 antibodies is simple and accurate for diagnosing lymph node metastases; estimating metastatic amount may be possible with different antibody concentrations. We are producing an SDB kit that uses these antibodies.
Title: Sentinel lymph node biopsy using intraoperative indocyanine green fluorescence imaging navigated with preoperative computed tomography lymphography for early breast cancer

Hajime Abe¹, Keiichi Yamazaki¹, Masao Ogawa¹, Masayasu Kawasaki¹, Kohri Yoneda¹ and Masao Kameyama¹. ¹Bell Land General Hospital, Sakai, Japan.

Body: Background: Sentinel lymph nodes (SLN) biopsy has been established as a standard of care in the treatment of early breast cancer. The combination of the radioisotope and dye-staining methods is the most accurate way to identify sentinel lymph nodes. We had reported a novel technique of SLN identification using fluorescence imaging of indocyanine green (ICG) injection. However, if any lymphatic vessels are injured, further fluorescence navigation will be difficult because of ICG contamination in the surgical field in overweight or obese patients. In this study, a new diagnostic approach for imaging lymphatic drainage and identifying SLN using preoperative computed tomography-lymphography (CTLG) and an intraoperative ICG fluorescence method was investigated.

Patients and method: Between January 2013 and April 2014,105 breast cancer patients without clinical evidence of lymph node metastasis were treated. On the day before the operation, CTLG was performed using 64-row multidetector CT. We performed an intradermal injection in the periareolar area, using 4 ml of contrast agent with 0.5 ml of local anesthetic. The contrasted lymph flow and SLN were identified in reconstructed three-dimensional imaging. The SLN spot was indicated by CT laser light navigator system. During the operation, fluorescence images were obtained using the fluorescence imaging system, Photodynamic Eye (pde-neo, Hamamatsu Photonics Co., Japan). After ICG was injected intradermally in to the periareolar skin, lymphatic drainage was observed with fluorescence images. SLN biopsy was performed by referring to the marker preoperatively placed on the CTLG. Moreover, we classified enhancement of SLN as “whole” and "partial" by CTLG with visual patterns, and examined the relation with SLN metastasis.

Results: The median age of the 105 patients was 63 (range 33 – 87) years old. CTLG and fluorescence imaging was safely performed in all patients. This method was visually easy to identify the location of SLN on the axillary skin even in obese patients. CTLG could visualize lymphatic flow and accurately identify SLN in 99 (94%) of 105 patients, whereas fluorescence imaging identified successfully lymphatic flow and SLN in all patients. Lymphatic flows of CTLG were completely consistent with those of fluorescence imaging. The number of SLN identified by CTLG was significantly lower than that by fluorescence imaging (1.1 vs. 1.6, p<0.01). Fifteen patients (14%) were found to have lymph node metastases pathologically, and five of them had micrometastases of lymph node. In 6 patients without detected SLN by CTLG, only one patient had lymph node metastasis. In case of partial enhancement of SLN with CTLG, the rate of positive metastasis was significant higher compared to the cases of whole enhancement (p<0.01).

Enhancement of SLNs by CTLG

Conclusion: This new navigation method of CTLG and fluorescence imaging revealed more easy and effective to detect SLN intraoperatively than fluorescence imaging alone. In addition, the information from CTLG may be helpful for the prediction of SLN metastasis.
Title: Not all sentinel lymph nodes are equal – A predictive model for axillary burden in early breast cancer

Yirong Sim¹, Sue Zann Lim¹, Shaun S Tan¹, Alvona Z Loh¹, Cindy Lim², Preetha Madhukumar², Gay H Ho², Veronique KM Tan² and Kong Wee Ong³. ¹Singapore General Hospital, Singapore, Singapore; ²National Cancer Centre, Singapore, Singapore and ³National University of Singapore, Singapore, Singapore.

Body: Introduction
The Z11 trial demonstrates that an axillary lymph node dissection (ALND) can be avoided in patients with low axillary burden who undergo breast conserving surgery (BCS), combined with whole-breast radiotherapy and systemic therapy. Our group propose a standardisation of sentinel lymph node biopsy (SLNB), incorporating 2 novel sentinel nodal stations (SNS) which represent sequential echelons of SLN draining the breast – the intercostalbrachial nerve (ICB) and the medial pectoral neurovascular bundle (MP). By increasing the specificity and positive predictive value of SLNB, we aim to identify a subgroup of patients who undergo mastectomy who can be spared from ALND and its associated complications.

Materials and Methods
313 female patients who underwent sentinel lymph node biopsy for breast cancer from 2 February 2012 to 19 December 2013 were prospectively studied. 12 patients had bilateral breast cancers, and each laterality was counted as distinct cases, giving a total of 325 cases. 7 had breast surgery performed prior to the SLNB, and the rest had their oncological surgery performed at the same setting of the SLNB. The surgeries were performed by three surgeons in the National Cancer Centre Singapore, using a specific surgical technique to identify SLN at the 2 SNS. Relevant patient demographics, status of SNS and the rates of metastatic non-sentinel lymph nodes were collected and analysed.

Results
A total of 325 SLNBs using the ICB and MP SNS were identified from 169 simple mastectomies, 35 skin sparing mastectomies, and 129 breast conserving surgeries. The median age was 56 (range 27-89). The ICB SLN and MP SLN were identified in 313 (96.3%) and 258 (79.4%) cases respectively. In 249 (76.6%) cases were both ICB and MP nodes identified, of which 55 (16.9%) had metastatic involvement of the SLN. An axillary clearance was performed if at least one ICB or MP node was positive, and only 27 (49.1%) had further axillary involvement. More than 2 positive SLNs had 100% positive predictive value for further axillary LN metastases. There was a low sensitivity (29.6%) and high false negative rate (70.4%) for positive axillary nodes in patients with ≤2 positive SLNs. MP nodal status, however, was 85.7% specific (p<0.001) and 48.1% sensitive (p=0.649) and a positive predictive value of 76.5% for axillary nodal involvement. Logistic regression also shows that MP node status is significant for predicting axillary nodal status (OR 5.57, p=0.006).

Conclusion
Our study shows that MP node status is specific, and has a positive predictive value for further axillary LN metastases. Therefore, we propose that in all patients who undergo SLNB with their BCS or mastectomy, an axillary clearance should be performed if the MP node is positive, regardless of the number of positive SLNs.
Title: Role of age, menopausal status and biological tumor characteristics on sentinel lymph node metastasis in early breast cancer patients with favorable prognostic features: A retrospective, mono institutional study on 345 cases

Nicla La Verde¹, Chiara Casiraghi², Chiara Dazzani¹, Irene Floriani³, Elena Biagioli³, Andrea Cordovana², Chiara Gerardi³, Gabriella Farina¹, Anna Maria Croce⁴, Filippo Bianchi⁴, Claudio Lunghi², Mauro Lamera³, Marcello Bonavita⁵, Elena Bernardi⁵ and Giorgio Gherardi⁴.

Fatebenefratelli e Oftalmico, Milan, Italy; ³Laboratory of Clinical Research, IRCCS â–“ Istituto di Ricerche Farmacologiche â–œMario Negriâ–”, Milan, Italy; ⁴A.O. Fatebenefratelli e Oftalmico, Milan, Italy and ⁵A.O. Fatebenefratelli e Oftalmico, Milan, Italy.

Body: Background: Sentinel lymph node biopsy (SLNB) is recognized as a standard procedure for women with early breast cancer. Recently some studies reported the futility of axillary lymph node dissection in patients (pts) who are SLN positive but bear favorable clinical and primary tumor biological characteristics. Since we believe that the choice of a proper axillary treatment in early breast cancer could be personalized and axillary SLNB could be avoided in specific subgroups of pts, we designed this study to identify key primary tumor characteristics and pts’ clinical features that could influence the indication to perform SLN biopsy.

Patients and methods: Retrospective analysis was carried out in women who had undergone surgery and SLNB for early breast cancer (pT1-2) from 2005 to 2013 at the Fatebenefratelli e Oftalmico Hospital in Milan, Italy. All SLNs were examined histologically in toto on seriated permanent sections. The association between SLN positivity and the following variables as age, menopausal status, tumor size, histological grading, presence of extensive "in situ" components and lymphovascular invasion (LVI), quantitative evaluation of Ki-67, HER2 expression, oestrogen and progesterone receptors, was assessed by means of univariate and multivariate logistic models.

Results: The records of 345 pts with early breast cancer who underwent surgery were retrieved. Mean age was 61 years and 79% pts were postmenopausal. 85% were treated with quadrantectomy and 66% had only one SLN removed. SLN metastasis was detected in 24% of cases. Tumor size was <2 cm in 76% of pts, and 86% were of luminal subtypes. Peritumoral LVI was detected in 32% of cases. At univariate analysis a statistically significant association was found between tumor size [odds ratio (OR) 1.05, confidence interval at 95% (95%CI) 1.01-1.08; p=0.005], histological grade (OR 1.50, 95%CI 1.04-2.16; p=0.029), presence of LVI (OR 3.81, 95%CI 2.27-6.37; p < .0001). At multivariate analysis only LVI confirmed to increase the risk of SLN positivity in the whole series (OR 3.26, 95%CI 1.89-5.64; p < .0001) as well as in subgroup of pts with luminal A and B subtype (OR 3.51, 95%CI 1.92-6.44; p < .0001). Negative and positive predictive values of LVI were 83.9% and 42.2%, respectively. Interestingly, in a pre-planned subgroup analysis according to menopausal status, an association between tumor dimension and SLN positivity was found in premenopausal women (OR 1.1, 95%CI 1.01-1.21; p < .034), while in postmenopausal pts LVI was associated with SLN positivity (OR 3.05, 95%CI 1.65-5.64; p < .0004).

Conclusions: Our data suggest that in a population with favorable early breast cancer (luminal subtypes, postmenopausal status and small tumour size) LVI increases the risk of SLN metastasis. These results are confirmed in luminal subgroup. In addition the absence of LVI has a significant negative predictive value. As far as menopausal status is concerned we found that the positivity of SLN is associated with tumor dimension in premenopausal and with LVI in postmenopausal women.
Title: In patients with micrometastatic in sentinel lymph node biopsies, involvement of the non-sentinel lymph nodes cannot be predicted by clinicopathological variables

Muhammad N Chauhan¹, Rajiv V Dave¹, Mauria Ghaus¹, Sana Ahmad¹, Craig Sayers¹, Zbigniew Kryjak¹ and Deedar Ali¹.
¹Pindefields Hospital, Aberford Road Wakefield, West Yorkshire, United Kingdom; ²Pindefields Hospital, Aberford Road Wakefield, West Yorkshire, United Kingdom; ³Pindefields Hospital, Aberford Road Wakefield, West Yorkshire, United Kingdom and ⁴Pindefields Hospital, Aberford Road Wakefield, West Yorkshire, United Kingdom.

Body: Background: The Sentinel Lymph Node Biopsy (SLNB) procedure is recognised to be an accurate method of staging the axilla in patients with early stage breast cancer. There remains a debate as to whether patients with micrometastases should undergo completion axillary lymph node dissection (CALND). We aimed to assess the indicators for positive non-sentinel lymph nodes (n-SLN) following CALND.

Methods: We retrospectively analysed our experience of SLNB between July 2008 to July 2013. A total of 1152 breast cancer patients underwent SLNB based on lymphoscintigraphy, intra-operative gamma probe detection, and blue dye mapping using 99mTc-nanocolloid and Patent Blue V injected peri-areola. Statistical analysis was performed using Fisher’s exact and \( \chi^2 \) for categorical data.

Results: Out of 1152 SLNB biopsies performed, 224 (19.5%) were positive for metastatic disease; macrometastases in 150 (67%), micrometastases in 72 (32%) and ITC in 2. CALND was not performed in 20 cases (9 macrometastases, 10 micrometastases, and 1 ITC), largely due to concerns regarding fitness for anesthesia. Macrometastases on SNLB were more likely to predict positive n-SLN on ANC (macrometastases; 39/141(27.7%) vs micrometastases; 9/62 (14.5%), \( p=0.029 \)). On univariate analysis, positive n-SLN in CALND for patients with micrometastases on SLNB was not predicted by grade (G0-G2; 6/43, and G3; 3/19, \( p=0.565 \)), size of primary breast tumour (<40mm; 8/58, \( \geq 40 \text{mm} \); 1/4, \( p=0.475 \)), lymphovascular invasion (5/30 vs 4/31, \( p=0.503 \)), age (<50 years; 3/24 vs \( \geq 50 \text{ years} \); 6/38, \( p=0.496 \)), or number of positive SLNB (all patients had <2 positive nodes on SLNB). Recurrences were detected in 4 patients, of which 1 was in a patient with micrometastases on SLNB. Out of the 4 recurrences, 3 were distant (liver and bone) and one was locoregional, with new disease in the contralateral breast.

Conclusion
In our series, 14.5% (9/62) of patients with micrometastases had positive n-SLB on CALND, which was not predicted by any clinicopathological characteristics. We have recently changed our practice toward not routinely offering CALND in patients with micrometastases, in keeping with current vogue. However, it is important to inform our patients that 14.5% of patients with micrometastases on SLNB may have positive n-SLN.
Title: Prognosis of metastatic internal mammary sentinel nodes (IMSN) in breast cancer

Eli Avisar¹, Shai Libson² and Eduardo Perez¹. ¹University of Miami Miller School of Medicine, Miami, FL and ²Ben Gurion University, Beer Sheva, Israel.

Body: Introduction:
The presence of positive internal mammary nodes has historically been associated with a significant worse prognosis. Recent studies have also demonstrated a worse prognosis associated with drainage to the internal mammary nodes. Intense search for those nodes, biopsy, appropriate staging and modern treatment for positive IMSN might improve outcome. We sought to study the prognosis of pathologically positive IMSN at our institution.

Methods:
A retrospective analysis of a prospectively collected database including all breast cancer patients identified with an IMSN that was biopsied between 2005 and 2012 was performed. Demographics, histologic markers, patterns of recurrence as well as survival data were collected. Univariate and multivariate analysis were performed.

Results:
Thirteen of 82 patients with a biopsied IMSN were metastatic (16%). In 8 of those (62%), the biopsy resulted in a change in staging. In all cases of positive IMSN additional radiation to the internal mammary chain was added. Eighteen percent (18%) of positive nodes did not show drainage to the internal mammary basin during Lymphoscintigraphy. There was no statistical difference in regional and distant recurrences between the patients with positive IMSN and those with negative IMSN. Furthermore there was no difference in disease specific survival.

Conclusions:
Intense search for IMSN presence and biopsy of those nodes is associated with changes in staging and treatment for metastatic IMSN. In our study, pathologically positive IMSN were associated with a non-inferior prognosis than negative IMSN.
Title: Axillary involvement in lobular breast cancer

Pilar Zamora¹, Covadonga Marti¹, Ana Roman¹, Jose M Oliver¹, Javier de Santiago¹ and Jose I Sanchez-Mendez¹. ¹Hospital Universitario La Paz, Madrid, Spain.

Body: Purpose:
Since the beginning of the use of the technique of selective sentinel node biopsy (SLNB), multiple models have been proposed to predict both the probability of involvement of the sentinel lymph node (SLN), and, in case it is positive, the likelihood of non-sentinel lymph node (NSLN) involvement.

Some of the factors that increase the likelihood of SN involvement (multifocallity, hormonal receptors, larger sizeâ–¦) are frequently found in invasive lobular carcinoma.

Invasive lobular carcinoma (ILC) is the second most common histologic type of invasive mammary carcinoma, comprising 5%–15% of all invasive breast carcinomas. However, in recent decades an increase in the relative incidence of this variant has been reported in the literature. This has been linked to the employment of hormone replacement therapy, the use of assisted reproduction techniques (IVF) or greater availability of diagnostic tools such as breast ultrasound or MRI that allow their better detection.

The aim of this study is to determine the extent of axillary involvement in both SLN and NSLN in patients with ILC

Patients and Methods
369 cases of infiltrating carcinoma candidates for SLNB technique between April 2010 and April 2013 were reviewed retrospectively.

Patients must have a diagnosis of breast cancer of any histological type, with a screening ultrasound without clinical suspicion of axillary involvement.

Cases of intraductal carcinoma that underwent SLNB were excluded and even those that were performed prior to neoadjuvant treatment.

Data on age, histological type, positivity / negativity of the SLN, implementation or not of axillary lymphadenectomy and outcome of involvement of NSLN were collected.

Statistical calculations were performed with SPSS.

Results
Of the 369 selected patients, 291 (79.9%) had invasive ductal carcinoma (IDC), 55 (15.1%) ILC and 18 other histological types (mucinous, colloid, tubular, papillary or mixed). The median age was 58.6 years.

SLN could not be found in 5 patients. 225 (61.8%) had a negative SLN. In 139 (38.2%) patients, SLN was positive, 64 of these cases showed micrometastasis while 75 presented macrometastasis.

Among IDC, 108 (37.1%) of the cases had a positive SLN, 53 (49.1%) of them with macrometastases.

Among ILC, 27 (49.1%) of the cases presented positive SLN, in 20 of them (74.1%) with macrometastasis.

Differences in both the SLN involvement and the presence of micrometastases observed between IDC and ILC were statistically significant (p< 0.001). In those cases were a lymph node dissection was performed, the probability of finding NSLN affection was 18.8% in the case of IDC compared to 55% in patients with ILC (p< 0.001).

Conclusions
Axillary lymph node involvement in the case of candidates for SLNB is more frequent and more extensive in patients with ILC than in patients with IDC.
Title: A new nomogram to predict axillary metastasis in breast cancer patients without axillary surgery

Valery Rodionov¹,², Vlada Cometova¹,², Sergey Panchenko¹,², Sereda Idrisova¹,², Yurij Savinov and Maria Rodionova.¹ Ulyanovsk State University, Ulyanovsk, Russian Federation; ²Ulyanovsk Regional Clinical Cancer Center, Ulyanovsk, Russian Federation and ³N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation.

Body: Background: Several studies have concentrated on finding a combination of predictive parameters to establish a mathematical model that can identify patients with no axillary metastasis for whom routine lymph node dissection could be safely avoided. We developed a new model of nomogram (the Ulyanovsk Cancer Center axillary lymph node metastasis nomogram, UCC-ALNM nomogram); it employs clinically and pathologically relevant variables and offers possible advantages over the others nomograms.

The purpose of the study: To assess the predictive power of UCC-ALNM nomogram.

Methods: A total of 530 breast cancer patients treated between 2008 and 2010 were used as the modeling group for validating the UCC-ALNM nomogram. Clinical and pathologic features of patients were assessed by multivariable logistic regression to predict the presence of axillary metastasis in breast cancer patients. The predictive accuracy of our nomogram was measured by calculating the area under the receiver-operating characteristic (ROC) curve (AUC). Clinical factors included into analysis were: patient’s age and localization of the primary tumor. Pathological factors evaluated were: traditional pathological criteria (primary tumor size, histological type, tumor grade, HR- and Her-2 status) and new total pathological index (Ulyanovsk prognostic index - UPI), introduced by pathologists of the Ulyanovsk Regional Cancer Center. UPI is total score of six main pathological criteria that characterize the malignancy of epithelial tumors: degree of cellular differentiation, cellular polymorphism, mitotic activity, growth pattern, lymphovascular invasion, stromal reaction.

Results: By the multivariate analysis, patient’s age (p=0.04), tumor size (p<0.001), UPI (p<0.001), PR (p<0.001) and Her2 status (p=0.02) were identified as independent predictors of axillary metastasis. The nomogram was then developed using the six variables associated with axillary metastasis: age, tumor size, PR, Her2, UPI.

The new model was accurate and discriminating with an AUC of 0.7510 when applied to the modeling group.

Conclusions: UPI is a new predictive factor of axillary metastasis in breast cancer patients. UCC-ALNM nomogram.
Title: Sentinel node mapping with fluorescein and comparison with methylene blue and technitium sulphur colloid in early breast cancer

Anurag Srivastava¹, Rajendra A Badwe², Amar Prem¹, Vani Parmar², Vuthaluru Seenu¹, Anita Dhar¹, Nita S Nair², Rohini Hawaldar² and Vaibhav Sanmali². ¹AIIMS, New Delhi, Delhi, India and ²Tata Memorial Hospital, Mumbai, Maharashtra, India.

Body: Background: Sentinel lymph node biopsy is currently standard of care in node negative early breast cancer. There are various tracers for detecting sentinel lymph nodes in breast cancer. Sentinel lymph node biopsy (SLNB) using Technetium tagged Sulphur colloid is a convenient and safe method to assess lymph node status. However, sulphur colloid is radioactive and its use needs gamma camera which is very costly and available in very few centers in India. Methylene blue dye is an economical alternative for sulphur colloid having identification rate similar to the isotope. However, it may react with hemoglobin forming meth-hemoglobin resulting in difficulty in pulse oximetry during operation and causes skin eruptions and necrosis. Hence, there is a need to identify a sensitive, inexpensive and safe dye for sentinel node biopsy. In this study we have investigated the effectiveness and safety of fluorescein in sentinel node biopsy in a cross-sectional analytical study compared to Methylene Blue and Technitium Sulphur colloid.

Methods: This trial was conducted at two centers : Tata Memorial Centre, Mumbai and All India Institute of Medical Sciences New Delhi in India. We examined 86 patients of early breast cancer with no palpable axillary nodes undergoing SLNB with three tracers (Sulphur colloid /Methylene blue / Sodium Fluorescein). Patients underwent complete axillary dissection after identification of sentinel node for validation of sentinel node biopsy. Hot nodes were identified using hand held gamma probe and fluorescent nodes were identified using Ultra Violet lamp. All nodes were examined with Haematoxylin and Eosin staining. Since this study is first with use of fluorescein for sentinel node biopsy in breast, we injected fluorescein at decreasing time interval from 12 hours to 5 minutes to ascertain the most appropriate time for injection of fluorescein in first 15 patients. The sentinel nodes were visualized only when fluorescein was injected 5 minutes before incision.

Results: Sentinel nodes could be identified in eighty out of eighty six patients by combined tracers. In 72 out of 86 patients hot nodes could be identified (83.7%) while in 54 out of 86 patients fluorescent nodes could be identified (62.8%). Blue nodes were identified in 64 out of 86 patients(74.4%). Fluorescein delineated the lymphatic pathway going from breast to axilla in most patients. No side effects of Fluoroscein were observed. Of 86 cases, histologically positive sentinel lymph node were found in 15 patients. False negative with combined three tracers was in 3/18 (16.6%) patients. False negative rate with individual tracers was sulphur colloid- 3/16 (18.8%), Fluorescein – 2/15(13.3%) and with Methylene blue – 2/17(11.8%).

Conclusions: Fluorescein can be used as a low cost and effective alternative in sentinel lymph node biopsy for carcinoma breast without the risk of radiation exposure. Moreover, excellent visualisation of lymphatic pathway during procedure can act as a guide to trace the sentinel node.
Body: Background:
Intra-operative sentinel node biopsy (SNB) is performed for clinically node negative invasive carcinoma (IC). Despite a negative result for metastasis from rapid frozen section (FS) diagnosis of intra-operative SNB, some cases may be diagnosed positive when permanent sections (PS) are analyzed (i.e., false negative). In order to reduce the false-negative rate, it is necessary to determine why macrometastases measuring greater than 2 mm cannot be accurately diagnosed using frozen specimens. The aim of this study was to compare the pathological characteristics of false-negative and positive cases of macrometastasis using FSs. We also reviewed whether there were differences in postoperative prognoses between positive and false-negative cases.

Methods:
We retrospectively reviewed 1632 intra-operative SNBs collected from 2008 to 2011 at St. Luke’s International Hospital, Tokyo, JAPAN. Of these, 980 patients had undergone surgery for the treatment of IC without neoadjuvant chemotherapy. Lymph nodes were sectioned every 2 mm and examined. For FSs, we performed hematoxylin and eosin (HE) staining, and for PSs, we used HE and cytokeratin (AE1/AE3) staining. Image J (NIH Image, Bethesda, MD, USA) was used for assessment of the metastatic area of lymph nodes. Micro- and macrometastases were defined as metastatic lesions measuring between 0.2 and 2 mm or measuring 2 mm or more, according to TMN classification.

Results:
Using FSs, we identified 104 patients (10.6%) who were positive for macrometastasis, 16 patients (1.6%) who were positive for micrometastasis, and 860 patients (87.8%) who were negative for metastasis. Of the negative cases, the result was changed to micrometastasis in 37 cases (4.3%) and to macrometastasis (false-negative cases) in 14 cases (1.6%). Ten of the 14 patients did not have additional axillary lymph nodes dissection. The mean age of the patients was 55.1 ± 3.1 years for false-negative cases and 52.3 ± 1.2 years for positive cases. In terms of histological features, there were statistically significant differences between false-negative and positive cases for invasive ductal carcinoma (IDC), invasive lobular carcinoma (ILC), and IDC plus ILC (p < 0.05). There were no statistically significant differences between false-negative and positive cases in terms of the total number of slices for lymph nodes (8.4 ± 1.6 vs. 9.7 ± 0.6, respectively; p = 0.41) but tendency in the number of slices for metastases (2.4 ± 1.2 vs. 4.8 ± 0.5, respectively; p = 0.07). The maximum area ratio of metastasis was significantly lower in false-negative cases than in positive cases (3.0% ± 0.1% vs. 20.0% ± 0.2%, respectively; p < 0.05). There was no significant difference in disease-free survival between false-negative and positive cases (p = 0.43).

Conclusions:
Although it is necessary to reduce false-negative cases, no difference in prognosis was detected in our study. False-negative cases had lower metastasis area ratios than positive cases diagnosed using rapid diagnosis of intra-operative SNBs, and ILC is known to be high in histological features. Therefore, using AE1/AE3 stain together with rapid diagnosis of intra-operative SNBs may lower the false-negative rate when a diagnosis includes ILC in pre-operation analysis.
Randomised controlled trial of stereotactic 11g vacuum-assisted or core biopsy for diagnosis and management of malignant microcalcification

Sara M Bundred¹, Jin Zhou¹, Anthony Maxwell¹, Sigrid Whiteside¹, Julie Morris¹, Janicke Harake² and Nigel J Bundred¹.
¹University Hospital of South Manchester NHS Foundation Trust, Manchester, United Kingdom and ²Royal Bolton Hospital, Bolton, Lancashire, United Kingdom.

Body: Background
Vacuum-assisted biopsy (VAB) is claimed to improve diagnosis of malignant microcalcification (MM) and prevent underestimation of invasive component compared to stereotactic core biopsy (SCNB) 14g biopsies. VAB is also reported to reduce requirement for further surgical procedures versus SCNB.

Methods
In a randomised controlled trial, we compared both techniques in the firstline diagnosis of MM and subsequent surgical management in two UK Breast Screening Units. Patients with MM were identified and gave written informed consent to the study before randomisation 1:1 to SCNB or VAB. Exclusions included bleeding diathesis or significant comorbidity preventing surgery. SCNB was performed by advanced radiography practitioners and VAB by experienced radiologists under local anaesthesia. Quality of life was assessed using EORTC QLQ-BR23 questionnaire: Pre-biopsy, 2, 6, and 12 months post-randomisation. The primary objective compared the final pathological diagnosis with the initial biopsy (VAB or SCNB) and required 110 patients to be randomised to show a 25% improvement in diagnostic accuracy with VAB compared to SCNB with a 90% power.

Results
Three quarters of MM investigated was less than 15mm in size. Overall 787 women were investigated for eligibility. 476 did not meet the inclusion criteria, 82 declined to participate and 100 met exclusion criteria. In total, 129 women were randomised. Both groups were evenly matched for age 57.2 years (range 47-75) and lesion size but VAB took longer (p<0.001) and produced on average, 4 more cores (12 versus 8) (p<0.01). Three (4.7%) VAB developed bleeding causing procedure abandonment. The PPV for biopsy of MM was 30.2% and 1 patient withdrew before the procedure. There was an 84% diagnostic accuracy of SCNB which precluded any effect on surgical outcome.

Both groups had significant Quality of Life (QOL) falls in Global Health (p<0.001) and Social Functioning over time (p<0.04) but no overall difference between groups was seen. At 12 months, body image scores fell and fatigue increased in patients undergoing surgery.

Conclusion
SCNB has equal accuracy as VAB in the firstline diagnosis of malignant microcalcification. Devicor provided the equipment to Dr S.B. and Prof. N.B., to do this study.
Title: A review of the accuracy of wire localisation using digital breast tomosynthesis (DBT) in a prospective series of 81 patients

Simon DH Holt¹, Khaldoun MY Nadi¹, Amrita Gurung¹, Helen R Williams¹, Anita M Huws¹ and Yousef M Sharaiha¹. ¹Prince Philip Hospital, Llanelli, Carmarthenshire, United Kingdom.

Body: Introduction: Digital breast tomosynthesis allows identification of impalpable lesions in three-dimensions. We have devised a technique for wire placement using a gridded plate that allows localisation of such lesions for subsequent surgical excision. Method: 81 consecutive cases were studied prospectively between Jan 2012 and May 2014. The localisation is usually performed by the operating surgeon under local anaesthetic shortly before the patient is transferred to the operating theatres. Our surgeons consider the optimal position for the tip of the wire to be 1 cm beyond and 1 cm to the side of the lesion placed using only the CC or lateral projection. The patient is positioned with the aperture of a gridded plate over the lesion needing to be surgically removed. A single DBT is acquired and the volumes reviewed. The lesion is identified and the depth in the breast recorded (Z coordinate). The ideal position for the wire is then marked in that plane and the volume scrolled through to bring the calibrated plate into focus. This identifies the X and Y coordinates, which are then recorded. The wire is then placed freehand in the line of the beam and a further DBT performed to check the position of the wire without needing to reposition the patient. A specimen x-ray is performed immediately following excision to confirm the target lesion is included. The results are verified at the subsequent multidisciplinary team (MDT) meeting.

Results: Once the target is identified, the average time for the localisation procedure and check DBT was 4 minutes. This series included both diagnostic (N=24, 30%) and therapeutic excisions (N=57, 70%). Patients presented both from screening (N=64, 79%) and symptomatically (N=17, 21%). The age range of the patients was 42-79y (mean 59y). 54 (67%) cases were undergoing excision for calcifications, 15 (19%) for impalpable masses, 11 (13%) for radial scars or distortions and 1 for glandular asymmetry. The final diagnoses following excision were IDC 34 (42%), DCIS 29 (36%), benign 13 (16%) and 1 case each of ILC, spindle cell tumour, mucinous carcinoma, phyllodes and pleomorphic LCIS.

In all cases the target lesion was shown to be present in the specimen x-ray, confirmed on histology and ratified by the MDT.

Conclusions: Wire localisation using DBT is a quick and accurate method of localising impalpable lesions for surgical excision.
Title: Retrospective analysis of the accuracy of ultrasound-guided core needle biopsy in the diagnosis of breast invasive ductal carcinoma: Experience in Chinese population

Wan Wang¹, Yongchuan Guo², Guixiang Tai³ and Zheli Xu⁴. ¹China-Japan Union Hospital of Jilin University, Changchun, Jilin, China; ²China-Japan Union Hospital, Jilin University, Changchun, Jilin, China; ³College of Basic Medical Science, Jilin University, Changchun, Jilin, China and ⁴China-Japan Union Hospital of Jilin University, Changchun, Jilin, China.

Body: Background: Percutaneous imaging-guided core needle biopsy is a reliable alternative to surgical biopsy for a histological diagnosis. Nowadays, core needle biopsy is considered to be the standard technique for histological diagnosis of breast lesions. However, the accuracy of ultrasound-guided core needle biopsy in predicting tumor grade, which is scored according to mitotic index, tubular differentiation, and nuclear atypia, is not well established. The aim of this study is to evaluate the concordance of histological diagnosis between ultrasound-guided core needle biopsies and subsequent excision specimens of breast invasive ductal carcinomas.

Methods: We retrospectively reviewed the medical records of 457 consecutive female breast invasive ductal carcinomas that were biopsied under sonographic guidance, using 14-gauge core needles exclusively, and that were subsequently excised surgically from June 2011 to May 2014. A minimum of four cores were taken per lesion. Tumor grade was assigned using the standard modified Scarff-Bloom-Richardson system. Core biopsy pathological diagnosis and grades were compared with final surgical excision specimens. The diagnostic coincidence rate and the agreement rate were expressed in percentages and in kappa statistics; the rates of overestimation and underestimation were also assessed. The correlation among tumor size (small, \( \leq 0.5 \) cm; medium, 0.6–1.9 cm; and large, \( \geq 2.0 \) cm), diagnostic coincidence rate, and agreement rate was also evaluated.

Results: Compared with the postoperative pathological diagnosis, the diagnostic coincidence rate of ultrasound-guided core needle biopsy was 94.75% (433/457). 24 cases were diagnosed with ductal carcinoma in situ or intraductal carcinoma by core needle biopsy. The overall agreement between core needle biopsy and surgical pathology grade was 67.28%. Agreement by biopsy grade was 73.33% (77/105) for grade 3, 70.97% (198/279) for grade 2, and 57.53% (42/73) for grade 1. Core needle biopsy underestimated 19.47% (89/457) and overestimated 10.07% (46/457) of the lesions. Small tumors were inclined to be more easily misdiagnosed as ductal carcinoma in situ or intraductal carcinoma, and large tumors were more likely to show underestimation rather than overestimation when discordant (\( p < 0.0001 \)).

Conclusion: Ultrasound-guided core needle biopsy accurately predicts high-grade breast tumors but is moderately accurate for lower-grade lesions. Large tumor size negatively impacts the accuracy of tumor grade found on biopsy and is associated with underestimation. Our finding indicates that ultrasound-guided core needle biopsy has important significance in estimating breast carcinoma grade and instructing clinical neoadjuvant chemotherapy.

Title: Are all small tumors low risk? Characterization of small invasive node negative breast cancers (BC) enrolled in the EORTC 10041/BIG 3-04 (MINDACT) trial

Konstantinos Tryfonidis¹, Leen Slaets², Giuseppe Viale³, Femke Snoo⁴, Laura Van't Veer⁵, Emiel Rutgers⁶, Martine Piccart⁷, Jan Bogaerts² and Fatima Cardoso⁸.

¹European Organization for Research and Treatment of Cancer (EORTC), Brussels, Belgium; ²European Organization for Research and Treatment of Cancer, Brussels, Belgium; ³European Institute of Oncology, University of Milan, Milan, Italy; ⁴Medical Affairs, Agenda, Amsterdam, Noord-Holland, Netherlands; ⁵University California, San Francisco, CA; ⁶Netherlands Cancer Institute, Amsterdam, Noord-Holland, Netherlands; ⁷Institute Jules Bordet, Brussels and Belgium and ⁸Breast Unit, Champalimaud Cancer Center, Lisbon, Portugal.

Body: Background: Adjuvant systemic therapy for subcentimetric N0 BC is controversial. These tumors have good prognosis, but a subgroup has high risk of relapse and requires adjuvant therapy. The best tool to identify this subgroup is unknown. We clinically and biologically characterize pT1abN0M0 tumors from patients enrolled in MINDACT. Patients and Methods: All MINDACT pts with pT1abN0 tumors were included. Descriptive statistical analysis included age, menopausal status, centrally assessed tumor grade, Ki67, ER, PR and HER-2 status. Cut-off value for high Ki67 was 20%. IHC subtypes are per 2013 St. Gallen consensus/ ESMO guidelines. Genomic tests (Mammaprint, Targetprint, BluePrint) were performed and their concordance rate with central pathology evaluated. We report clinical (modified version of adjuvant online!) and genomic risk assessment (MammaPrint) for these patients. Survival data will be reported after MINDACT primary analysis. Results: 826 patients with T1abN0 tumors were enrolled in MINDACT, [12.3% of all patients (6694) and 16% of all N0 tumors]; 310 (35%) patients were ≥ 60 years and 537 (65%) were postmenopausal. Most (710; 86%) samples were tested by central pathology. Tumors were mainly ductal (579; 81.5%), ER+ (650; 91.5%), and PR+ (593; 83.5%); 44 (6.2%) were HER-2+; 520 (73.2%) had a low Ki67 (& 24.5%) had high Ki67 labeling index; 80 (11.3%) were grade 3 & 328 (46.2%) grade 2 tumors. According to Targetprint, 761/826 (92.1%) tumors were ER+; 624/826 (75.5%) PR+; 45/826 (5.4%) HER2+. Concordance between Targetprint and central pathology was higher for ER (kappa=0.90) and lower for PR and HER2 (kappa=0.60 and 0.73 resp). Molecular subtype classification by IHC surrogates showed 420/710 (59.2%) Luminal A tumors; 189/710 (26.6%) Luminal B; 36/710 (5.1%) Luminal B/HER2+; 8/710 tumors (1.1%) HER-2+ and 37/710 (5.2%) TNBC. Using BluePrint 739/826 (89.5%) were Luminal; 29/826 (3.5%) HER-2+ and 58/826 (7.0%) basal. Combining BluePrint and Mammaprint 609/826 (73.7%) tumors were Luminal A & 129/826 (15.6%) Luminal B. Agreement between Mammaprint and Ki67 for distinction of luminal A vs B/HER-2 neg. tumors was low (kappa=0.31), similar to the overall MINDACT results (kappa=0.35). Using clinical risk assessment 820/826 (99.3%) were low-risk (CL). Using genomic risk assessment 624/826 (75.5%) were low risk (GL) and 201/826 (24.3%) were high-risk (GH). Overall, 624/826 (75.5%) were both CL/GL and 196/826 (23.7%) were CL/GH. The percentage of discordant CL/GH cases among T1abN0 tumors (196/826, 23.7%) is higher than in all MINDACT cohort (592/6694, 8.9%) and among T1c-2-3N0 tumors (381/4462, 8.5%). T1ab tumors were mainly 720/826 (87.2%) treated with BCS and radiotherapy; adjuvant treatment and compliance rate will be available at the meeting.

Conclusions: 1) Results show biological characteristics are relevant for T1abN0 BC & that size/nodal status could be insufficient determinants of adjuvant systemic therapy. 2) A significant portion (23.7%) of such tumors, clinically classified as low risk, was genomically high risk by MammaPrint. 3) IHC surrogates don't always accurately reflect genomic molecular subtyping.

Title: Incidence of actionable genomic alterations in metastatic breast cancer: A prospective study

Raquel E Reinbolt¹, Katlyn Tolliver¹, Mahmoud Abdel-Rasoul³, Cynthia Timmers², Bhuvaneswari Ramaswamy¹, Rachel M Layman¹, Robert Wesolowski¹, Maryam B Lustberg¹, Ewa Mrozek¹, Susan Ottman¹, James Chen², Charles Shapiro¹, Michael C Ostrowski², Gustavo W Leone² and Erin Macrae¹. ¹Ohio State University Comprehensive Cancer Center & The Stefanie Spielman Comprehensive Breast Center, Columbus, OH; ²Ohio State University Comprehensive Cancer Center, Columbus, OH and ³Ohio State University, Columbus, OH.

Body: Introduction: Foundation Medicine Incorporated (FMI) uses next generation sequencing (NGS) to simultaneously identify oncogenic molecular events and match targeted therapies to these alterations. We conducted a prospective study of the FMI test to describe the incidence of actionable genomic alterations found in advanced breast cancer patients.

Methods: This is a prospective, single center, single-arm trial in advanced breast cancer patients designed to assess FMI testing’s feasibility and impact. Adult metastatic breast cancer patients with an estimated survival of ≥ 3 months were included, had tumor sample available for testing, and were within 10 weeks of starting their current therapy line. A massively-parallel sequencing platform (FoundationOne™) used the patient’s tumor (FFPE tissue) to sequence for 236 cancer-related genes plus 47 introns of 19 genes often rearranged in cancer to high depth (>500x). Genomic alterations were categorized as actionable if linked to an approved therapy in the solid tumor of study or another malignancy, a known or suspected contraindication to a given therapy, or a clinical trial linked to the alteration. The number of genomic alterations was quantified; genes with > 1 alteration were counted once.

Results: Forty-nine patients were consented to FMI testing. Forty patients (82%) successfully completed testing; analysis was insufficient in 6 tissue samples, 2 failed DNA extraction, and 1 patient’s tissue was not received. Of the 8 unsuccessful tests, sampling from the bone (50%) and liver (38%) were the most common sites of failure. Thirty-seven reports have been received; 27 (73%) samples were taken from metastatic tissues, 10 (27%) from the primary breast tumor. A total of 192 actionable alterations were detected in tumors tested, with a median of 5 (range 1-11) alterations found per patient. Amplifications comprised 87 alterations, 105 were a base substitution, insertion/deletion or other copy number alteration. Of the 192 alterations, the TP53 gene was the most often altered [n=22 (11%)] and most frequent in ER/PR/HER2-neu negative breast tumors. Alterations in PIK3CA [n=16 (8%)] and ZNF217 [n=8 (4%)] were the 2nd and 3rd most commonly altered genes. The NGS report provided 24 of the 37 patients (65%) with a recommended FDA approved breast therapy; an additional 24 patients (65%) were suggested a non-breast FDA approved therapy. At least 1 potential treatment or clinical trial was proposed to 36 patients (97%) with everolimus (n=30) and temsirolimus (n=30) the most commonly recommended FDA approved interventions, and trametinib (n=6), regorafenib (n=6), and pazopanib (n=6) the next most commonly suggested interventions. Patients had a median of 3 (range 0-7) genomic alterations paired with a recommended clinical trial.

Conclusions: This prospective study shows NGS testing in advanced breast cancer patients is successful in over 80% of patients screened. Two-thirds of patients were recommended a FDA approved therapy and nearly all patients were suggested at least one potential clinical trial. Further studies to assess barriers to patients’ access to these recommended targeted therapies are currently underway.
Title: Comparative analysis of somatic mutations in matched primary vs metastatic triple-negative breast cancers

Irene Cherni¹, Maren K Levin², Joyce A O'Shaughnessy²,³,⁴ and John D Carpten¹. ¹Translational Genomics Research Institute, Phoenix, AZ; ²Baylor Sammons Cancer Center, Dallas, TX; ³Texas Oncology, Austin, TX and ⁴US Oncology.

Body: Background. Treatment of triple-negative breast cancer (TNBC) is clinically challenging due to disease heterogeneity and aggressiveness which often result in high recurrence and mortality rates. We have previously reported on genomic alterations found in 14 metastatic TNBC tumors (Craig et al 2012) uncovered through whole-genome and transcriptome sequencing and found that majority of tumor changes in our cohort converged on RAS/RAF/MEK/ERK and PI3K/AKT/mTOR pathways revealing potential therapeutic targets. In this study, we interrogated patients’ matched primary and metastatic cancers using exome sequencing. Differentiating between primary and metastasis-specific genomic alterations will further our understanding of TNBC recurrence.

Methods. Tumor tissue was microdissected from 10μM FFPE sections from primary tumors of nine TNBC patients. DNA was extracted using Qiagen AllPrep kit. Whole-genome libraries were prepared from >250ng of DNA using Kapa-on–Bead method. Exomes were captured using All Exon V5 capture kit (Agilent Technologies) and sequenced on Illumina HiSeq. List of somatic variants (SNVs) in primary tissue was generated using Seurat variant caller and manually compared with the SNVs uncovered previously in metastatic tumors. Presence (or absence) of all reported somatic SNVs was visually confirmed in IGV genome viewer.

Results. Our analysis revealed the majority of somatic mutations found in metastatic lesions were also present in the primary tissue (64.3% on average). Patient TNBC03 had an unusually high number of new mutations in the lung metastatic lesion (72.7%). All TP53 mutations in our cohort were an early event present in both primary and metastatic tissues. In patient TNBC01, acquired mutation in NF1 - an upstream negative regulator of RAS pathway - in addition to pre-existing PTEN deletion, CTNNA1 underexpression and RB1 mutation - suggests RAS pathway addiction which could have been responsible for disease recurrence in this patient. Interestingly, NEDD4 mutation was found in a lung metastasis of another patient whose disease was refractory to BEZ235 (PI3K/mTOR inhibitor) treatment. NEDD4 has recently been shown to be an upstream regulator of the PI3K pathway and a possible therapeutic target in cancers with downregulated PTEN. Additional select acquired mutations in metastatic lesions of our cohort included FGF14, ABCB10, MDM2, KIF1C, ATAD2B, PTPLAD2, MDM20, TDRD1, and USP6. Mutated CDH5 was found in metastases in 2 of 9 patients.

Conclusion. Our findings demonstrate the complexity and variability in somatic events underlying TNBC recurrence, reinforcing the need to re-biopsy metastatic TNBC lesions and to employ combination targeted therapies wherever possible.

**Title:** The heterogeneous clinical behavior of luminal breast cancers is associated with different mutational landscapes

Giampaolo Bianchini¹, Eugenia Galeota¹, Tingting Jiang², Maurizio Callari³, Milvia Zambetti¹, Takayuki Iwamoto⁴, Thomas Karn⁵, Christos Hatzis², Lajos Pusztai² and Luca Gianni¹. ¹IRCCS Ospedale San Raffaele, Milan, Italy; ²Yale School of Medicine, New Haven, CT; ³IRCCS Istituto nazionale dei Tumori, Milan, Italy; ⁴Okayama University Hospital, Okayama, Japan and ⁵Goethe-University, Frankfurt, Germany.

**Body:** Background: Genomic studies in estrogen-receptor (ER) positive breast cancer showed few commonly mutated genes and suggested that tumors with higher background of mutation rate were enriched in intrinsic aromatase-inhibitor-resistant tumors (Ellis MJ Nature 2012). Different combinations of proliferation (PROL) and estrogen-receptor related genes (ERS) allow the prediction of the risk of recurrence and endocrine treatment sensitivity (Bianchini G Breast Cancer Res 2013). The highPROL/lowERS is enriched in intrinsic endocrine resistant tumors. We explored whether different genomic alterations could contribute to the different clinical behavior of groups defined by PROL and ERS.

Method: We defined luminal breast cancers by PAM50 and retrieved gene expression and whole-exome sequencing data of 324 luminal breast cancer cases from the Cancer Genome Atlas (TCGA). PROL and ERS were calculated as previously reported. Low and high expression groups were defined by median cut-points (Bianchini G Breast Cancer Res 2013). As a metric of the background mutation rate of each sample, we used the overall mutation frequency in whole exome (Kandoth C Nature 2013). The most frequently mutated genes (TP53, PIK3CA, MAP2K4, MAP3K1, GATA3, CDH1) were also assessed for their association with PROL and ERS defined groups.

Results: The average number of mutations (Nmut) was 44.4 (5-366). High and low proliferation groups had different mutation frequency (average Nmut 53.6 and 35.3, respectively; p=6.1E-06). LowERS group also had a higher Nmut (average Nmut 54.4 vs. 34.5 in high ERS; p=1.2E-06). Notably, neither high or low expression of the ER gene (p=0.89), nor positive and negative progesterone receptor by immunohistochemistry (p=0.69) were associated with Nmut. LowERS group was associated with higher Nmut in luminal A (p=0.005) and B (p=0.006) subtypes. The group with highPROL and lowERS had the highest Nmut (average 62.1), which was not significantly different from basal-like tumors. HighPROL/lowERS was significantly associated with higher frequency of mutTP53 (32.3%) and lower rates of mutPIK3CA (28.1%), mutMAP2K4 and/or mutMAP3K1 (7.2%) and mutCHD1 (3.1%). The lowPROL/highERS had the lowest Nmut (average 29.8), with the higher rate of mutPIK3CA (61.4%) and mutMAP2K4 and/or mutMAP3K1 (29.2%), and lower rate of mutTP53 (6.7%).

Discussion: In ER-positive breast cancers, the highPROL/lowERS group, which is characterized by the highest risk of early recurrences despite endocrine treatment and chemotherapy, poor down-regulation of Ki67 after neoadjuvant aromatase-inhibitor (AI), but the highest rate of pCR after neoadjuvant chemotherapy, was also associated with the highest frequency of mutations, of the same order of magnitude of basal-like tumors. This data is in line with the observation that the number of mutations is linked to intrinsic resistance to neoadjuvant AlS (Ellis MJ Nature 2012). These data could be also informative for interpreting results of the combination of everolimus and endocrine therapy ( exemestane or tamoxifen) that suggest higher efficacy in tumors with acquired endocrine resistance (lower mutation rate) compared to intrinsic or primary endocrine resistance (higher mutation rate).
Title: FoundationOne profiling of TSC1 and TSC2-mutated advanced breast cancers

Norma A Palma¹, Juliann Chmielecki¹, Garrett Frampton¹, Siraj Ali¹, Maren Levin³, Jeffrey S Ross¹,², Deborah Morosini¹, Gary Palmer¹, Vincent A Miller¹, Phil Stephens¹ and Joyce O'Shaughnessy³. ¹Foundation Medicine, Cambridge, MA; ²Albany Medical College, Albany, NY and ³Baylor Charles A. Sammons Cancer Center, Texas Oncology, US Oncology, Dallas, TX.

Body: Background: The TSC1/TSC2 complex inhibits the mTOR pathway. Loss of function of this complex leads to hyperperactivation of the mTOR pathway which promotes growth and survival. Few studies have examined the role of TSC1 and TSC2 mutations in breast cancer and as a clinically relevant target for molecularly targeted therapy, such as everolimus, a rapamycin analog.

Methods: Hybridization capture of 3769 exons of 236 cancer-related genes and 47 introns from 19 genes that are frequently rearranged in cancer were fully sequenced to high, uniform coverage from a commercial CLIA-certified laboratory (Foundation Medicine).

Results: 30 of 2,208 breast cancer pt samples (1.3%) harbored either TSC1 (13/30, 43%) or TSC2 (17/30, 56%) genomic alterations (GAs). The samples with TSC1/2 consisted of breast carcinoma n.o.s. (17/30) and invasive ductal carcinoma (12/30); one invasive lobular carcinoma (ILC) harbored a TSC2 alteration. Sequencing was performed on metastatic (18/30, 60%) and primary (12/30, 40%) tumors. All TSC1 alterations resulted in truncation of the protein product; TSC2 GA consisted of truncations (14/17) and point mutations (3/17). TSC1/2 GAs frequently co-occurred with GAs in TP53 (19/30; 63%) and amplifications of MYC (9/30; 30%) and FGFR1 (7/30; 23%). Of the TSC1/2-mutant cases where hormone receptor and HER2/neu status was known (23/30), 65% were ER-/PR-/HER2- (TNBC), 26% were ER+/HER2- and 9% were ER-/HER2+.

Patient case: We describe a postmenopausal node positive ILC (ER+/PR+/HER2-) pt who received adjuvant chemotherapy followed by 9 yrs adjuvant anastrazole then with disease recurrence. On FoundationOne testing a TSC2 A1141T missense mutation, along with GAs in CDH1, ETV6, and CSF1R, were found in her metastatic disease in the soft tissues of her left orbit associated with substantial swelling resulting in loss of vision. While TSC2 A1141T has not been functionally characterized, in vitro and in vivo data suggest sensitivity to mTOR inhibitors. Her disease stabilized but did not decrease in size with vinorelbine + capecitabine. She was treated with letrozole + everolimus and had a near clinical complete response with restoration of vision for 5 + months. Collection of clinical data on additional pts is currently ongoing.

Conclusion: 1.3% of breast cancer cases harbored GAs in either TSC1 or TSC2. The majority of TSC1/2 GAs cause inactivation of these negative regulatory proteins leading to activation of the mTOR signaling pathway. TSC1/2 GAs were enriched for TNBC (65%) versus non-TNBC (35%) (p= 0.077; Fisher's exact test). Truncation of TSC1/2 occurred at multiple codons, underscoring the importance of examining the entire coding region of tumor suppressor genes for these inactivating events. Comprehensive genomic profiling has the potential to identify the broad spectrum of these inactivating events, a subset of which may be clinically relevant.
Deep clonal profiling identifies distinct mechanisms of heterogeneity and evolution in breast cancer

Princy Francis¹, Lucretia M Alvarez¹, Elizabeth Lenkiewicz¹, Mia Champion¹, Lisa Evers¹, Karen L Anderson¹, Ann E McCullough¹, Michael T Barrett¹ and Barbara Pockaj¹. Mayo Clinic, Scottsdale, AZ.

Background: Breast tumors exhibit intratumor heterogeneity resulting in targeted therapy resistance and other challenges in disease management. To address the sources of heterogeneity, we performed a unique, in-depth analysis of clonal architecture in primary chemoradiation-naïve breast cancers. We combined DNA content-based flow cytometry and ploidy analysis with aCGH and next-generation sequencing (NGS) in multiple biopsies from the tumors and involved lymph nodes (LNs).

Material and methods: We used DNA content-based flow sorting to isolate nuclei from distinct populations of diploid and aneuploid tumor cells in surgical tumor samples from two chemoradiation-naïve patients. Each sorted tumor cell population was interrogated with aCGH and exome NGS. In Patient #1, we used 12 fresh frozen sections morphologically mapped from within a HER2+, ER+, PR- primary invasive ductal carcinoma (IDC) of histological grade 3 with LN involvement and 2-3 sections from 2 out of 5 LNs. In Patient #2, 11 morphologically mapped fresh frozen sections were analyzed from a grade 2, ER+, PR+, HER2+, BRCA2 mutant LN- IDC. In parallel, matching samples were processed for IHC assays.

Results: We identified multiple co-existing aneuploid populations within the biopsies. The 17 primary and LN biopsies from Patient #1 fell into 6 distinct ploidy groups albeit with aberrant but homogenous aCGH profiles, characterized by SARC amplification and homozygous deletions in ROBO1 and ROBO2. In contrast a dominant ploidy was identified throughout Patient #2 but with heterogeneous aCGH profiles. Mutation profiles obtained through exome sequencing further confirmed that ploidy was the main driver in Patient #1 whereas copy number aberrations played the key role in Patient #2 with the BRCA2 mutation (R3129X). A dendrogram based on exome variant calls of the aneuploid populations in Patient #1 strongly correlated with ploidy group and further revealed the specific clonal population characterized by a 5N ploidy and homozygous mutations in TP53 and PIK3CA as the progenitor to the ploidies present in the distant LNs. Strikingly, both patients had no HER2 amplification or mutation across their clonal populations, contradicting the initial IHC staining in a single core biopsy.

Conclusions: Rather than inferring the presence of distinct tumor cell populations, our novel flow-sorting based approach of first identifying the clonal populations and then interrogating their genomes, provides an objective method of exploring the sources and clinical significance of tumor heterogeneity. Our approach of clonal analysis has broad implications in the study of tumor heterogeneity and the identification of drivers in breast and other solid tumors that can advance more effective treatment and clinical management of patients with this disease.
Title: Mutational landscape of metaplastic breast carcinomas

Charlotte KY Ng1, Britta Weigelt1, Salvatore Piscuoglio1, Y Hannah Wen1, Maria R De Filippo1, Luciano G Martelotto1, Rachael Natraj1, Raymond Lim1, Edi Brogi1, Larry Norton3, Anne Vincent-Salomon4 and Jorge S Reis-Filho1. 1Memorial Sloan Kettering Cancer Center, New York, NY; 2Breakthrough Breast Cancer Research Centre, The Institute of Cancer Research, London, United Kingdom; 3Memorial Sloan Kettering Cancer Center, New York, NY and 4Institut Curie, Paris, France.

Body: Introduction: Metaplastic breast carcinoma (MBC) is an aggressive histologic type of breast cancer, which preferentially displays a triple-negative phenotype. These tumors are characterized by the presence of malignant cells exhibiting differentiation towards squamous epithelium or mesenchymal elements, including spindle, chondroid, osseous and rhabdoid differentiation. Unlike other rare histologic types of breast cancer such as adenoid cystic and secretory carcinomas, which are underpinned by the MYB-NFIB and ETV6-NTRK3 fusion genes respectively, pathognomonic genetic alterations have not been identified in MBC. It has been suggested, however, that the frequency of PIK3CA somatic mutations would be significantly higher in MBCs than in other forms of triple-negative disease. Here we sought to characterize the mutational landscape of MBCs by means of high-depth whole exome sequencing analysis.

Material and Methods: Twenty-one triple-negative MBCs were retrieved from the authors' institutions. Representative sections from frozen blocks were microdissected to ensure tumor cell content greater than 50%. DNA samples extracted from microdissected tumor and matched peripheral blood leukocytes were subjected to high-depth (250x) whole exome sequencing on an Illumina GAIIx or HiSeq2000. Somatic point mutations were called using MuTect and somatic insertions and deletions (indels) were called using Strelka, Varscan2 and Haplotype Caller. Potentially pathogenic mutations were predicted using computational algorithms including PolyPhen-2, Mutation Taster, Mutation Assessor, CHASM and FATHMM. Significantly mutated genes were identified using MutSigCV. Pathway and network enrichment analysis of mutations was performed with Ingenuity Pathway Analysis and HOTNET. The genomic landscape of MBCs was compared with that of triple-negative breast cancers (TNBCs) analyzed as part of The Cancer Genome Atlas project.

Results: A mean of 135 somatic non-synonymous point mutations and indels were identified per MBC. The most frequently mutated gene was TP53, found in 12/21 cases (57%), and the only significantly mutated gene as defined by MutSigCV (q<0.01). The repertoire of somatic mutations found in MBCs was qualitatively similar to that of TNBCs of no special type, and recurrently mutated genes were altered at similar frequencies in MBCs and TNBCs of no special type. When somatic mutations were annotated in pathways and networks, MBCs were found to have potentially pathogenic mutations affecting genes directly related to the PI3K pathway, including pathogenic non-synonymous mutations affecting PIK3CA, PIK3R1, PIK3R2, PIK3C2B, PIK3C2G and PTEN, significantly more frequently than TNBCs of no special type (10 out of 21 MBCs vs. 11 out of 62 TNBCs; Fisher's exact test p-value=0.0099).

Conclusion: The majority (57%) of MBCs harbored non-synonymous mutations affecting TP53. While the frequencies of mutations affecting recurrently mutated genes in MBCs are similar to those found in other forms of TNBCs, MBCs significantly more frequently harbor mutations affecting PI3K pathway-related genes than TNBCs of no special type.
Benchmarking mutation function prediction algorithms using validated cancer driver and passenger mutations

Maria R De Filippo¹, Charlotte KY Ng¹, Jorge S Reis-Filho¹ and Britta Weigelt¹. ¹Memorial Sloan Kettering Cancer Center, New York, NY.

Background: Massively parallel sequencing studies have identified large numbers of mutations of unknown biologic significance. There is a pressing need for computational methods to predict and distinguish neutral from potentially pathogenic mutations accurately, to help identify those mutations worth exploring experimentally and clinically. Although various bioinformatic algorithms are available, they are based on different methodologies and assumptions, and their predictions for the same mutations are not always concordant. In this study, we sought to benchmark the performance of 17 prediction algorithms using functionally validated and pathognomonic mutations.

Methods: We curated the literature for functionally validated and pathognomonic mutations as our positive dataset (i.e. pathogenic mutations). For the negative dataset (i.e. neutral mutations), we retrieved variants from the dbSNP database, including only those with minor allele frequency >25%. We compiled a total of 7975 mutations (875 pathogenic and 7100 neutral). The performance of each prediction algorithm, namely accuracy, specificity, sensitivity, positive predictive value (PPV) and negative predictive value (NPV), were defined using the positive and negative datasets described above. Confidence intervals were calculated by sub-sampling 2/3 of the functionally pathogenic mutations and equal number of neutral mutations 500 times. To reduce the bias introduced by mutations included in the COSMIC database, we excluded those found in COSMIC v67, resulting in 6048 mutations (212 pathogenic and 5835 neutral), and re-evaluated the performance of each prediction algorithm.

Results: Our analysis revealed that the overall accuracy varied considerably, with a median of 87% (range 78%-97%). In terms of accuracy, FATHMM (cancer) statistically outperformed all other prediction algorithms (97%, 95% confidence interval (CI) 96%-98%), followed by MutationTaster 2 (94%, 95% CI 93%-95%). Sensitivity and specificity also varied (median 85%, range 77%-96% and median 89%, range 71%-100%, respectively). The most sensitive prediction algorithm, FATHMM (cancer) (96%, 95% CI 95%-97%) statistically outperformed all others. The most specific prediction algorithm was CHASM (breast) (100%, 95% CI 94%-100%). While CHASM (breast) had the highest PPV (100%, 95% CI 99%-100%), FATHMM (cancer) had statistically better NPV than all other prediction algorithms (96%, 95% CI 95%-97%). When COSMIC mutations were removed, FATHMM (cancer) remained the most accurate (93%, 95% CI 91%-95%) though the difference was not statistically significant. In this context, CanDrA (breast) was the most sensitive prediction algorithm (95%, 95% CI 93%-97%) and had the highest NPV (93%, 95% CI 90%-96%), while CHASM (breast) was the most specific prediction algorithm (100%, 95% CI 99%-100%) and had the best PPV (99%, 95% CI 97%-100%).

Conclusions: Our results demonstrate that functional prediction algorithms varied in performance. Using this dataset of mutations, FATHMM (cancer) outperformed all other prediction algorithms in terms of accuracy, sensitivity and NPV, and remained the most accurate even when mutations catalogued in the COSMIC database were excluded.
Title: Comprehensive somatic SNV and CNV profiling for triple-negative breast cancer patients by targeted next-generation sequencing

Taegyun Yun\(^1\), Byung-Chul Lee\(^1\), Jungsun Park\(^1\), Dongyoon Park\(^1\), Tae-Kyung Yoo\(^2\), Min Kyoong Kim\(^2\) and Wonshik Han\(^2\).

\(^1\)Bioinformatics Tech. Lab, Healthcare Group, Future Technology R&D Division, SK telecom, Seongnam-si, Gyeonggi-do, Korea and \(^2\)Seoul National University College of Medicine, Seoul, Korea.

Body: Introduction: Triple-negative breast cancer is a subtype of breast cancer lacking expression of estrogen receptor, progesterone receptor and HER2/neu protein markers. Despite having the worse prognosis, currently there is no molecular target for this subtype. To discover the clues for therapeutic targets of TNBC, we examined somatic Single Nucleotide Variation (SNV) and Copy Number Variation (CNV) profiling of TNBC patients using targeted next-generation sequencing (NGS).

Methods: A total of 414 breast cancer and normal breast samples were collected at Seoul National University Hospital (SNUH) from 1995 to 2013. By sample condition, 94 samples were frozen tissues (47 tumor-normal matched pair), and 320 samples were formalin-fixed and paraffin-embedded (FFPE) tissues (155 tumor-normal matched pair; Tumor 164, Normal 156). Genomic DNA was extracted from samples and target enrichment was done by using Agilent SureSelect Human Kinome Panel (612 genes including over 500 kinases). The paired-end libraries were constructed and sequenced on Illumina HiSeq 2000 instrument with average 250x depth coverage. Generated sequence reads were aligned to human genome hg19 with bwa algorithm, and somatic SNV and CNV were identified using VarScan2 algorithm. To confirm the existence of identified somatic SNV and CNV, we carried out SNP microarray experiment (Illumina Human Omni5 Exome microarray) for 46 pairs of frozen tissue samples. There were 18,720 SNP probes in SNP microarray covering target region of kinome panel. If the same SNV and CNV were detected in both NGS and microarray data, we considered them validated.

Results: In 46 paired frozen samples, 610 somatic SNVs were detected. The most frequent and non-synonymous mutations were in PIK3CA (8.6%), BMPR1A (4.3%), FES (4.3%), TP53 (4.3%), ROCK1 (4.3%), PAK2 (4.3%), CDK18 (4.3%), OBSCN (4.3%), LRRK1 (4.3%), CDC6 (4.3%), PIKFYVE (4.3%), and FGFR3 (4.3%). Chromosomal aberration was detected in chromosome 1 (10 samples) and chromosome 8 (11 samples). 242 somatic CNV were found in 157 genes in 46 patients, but 99 gene amplifications showed only single occurrence. In other words, TNBC sample displayed highly heterogeneous CNV profile. However, we detected two frequently amplified genes; PKHD1L1 (13%) and NRPB2 (10.9%). Further analysis on NGS data of 155 pairs of FFPE samples is in process to validate the results.

Conclusion: We investigated comprehensive somatic mutation profile in matched pair TNBC samples. Although these samples showed highly heterogeneous mutation profile, it’s possible to detect some interesting SNV and CNV with over 4% frequency. Further analysis may illuminate clinical meaning of those alterations.
**Title:** Interaction between smoking history and gene expression levels impacts survival of breast carcinoma patients

James L Wittliff¹, Sarah A Andres¹, Mohammad A Alatoum¹, Katie E Bickett¹, Theodore S Kalbfleisch¹ and Guy N Brock¹.

¹University of Louisville, Louisville, KY.

**Body:** Our investigations explore the association of cigarette smoking on breast cancer risk of recurrence and progression, in contrast to studies that focused on tobacco use and risk of breast cancer occurrence. The goal was to decipher the interaction between smoking history and expression levels of 22 gene candidates selected from microarray data obtained from laser capture microdissected carcinoma cells from 247 de-identified patient tissue biopsies on disease recurrence and overall patient survival of breast cancer patients. qRT-PCR was used to determine expression levels for NAT1, NAT2, COMT, SOD1, SOD2, BRCA1, BRCA2, APOC1, ARID1B, CTNNBL1, MSX1, UBE2F, IRF2, NCOA1, LECT2, THAP4, RIPK1, AGPAT1, C7orf23, CENPN, CETN1 and YTHDC2 selected from a previous study for 50 breast cancer patients with a history of cigarette smoking and 51 patients who had never smoked. For smokers and non-smokers separately, L1-penalized multivariable Cox regression models were fit to predict patient disease-free and overall survival, with 1000 splits of the data into training (70%) and test (30%) sets to determine predictive accuracy based on the C-index. The LASSO penalty was used to perform variable selection in each of the training sets, and a permutation procedure was used to determine a significance threshold for the number of times a variable was kept in the model. Multivariable analyses using the LASSO revealed CENPN, CETN1, CYP1A1, IRF2, LECT2, and NCOA1 to be significant predictors for both disease recurrence and mortality among smokers. Additionally, COMT was highly associated with recurrence, and NAT1 and RIPK1 were associated with mortality. In contrast, only IRF2, CETN1, and CYP1A1 were significant for disease recurrence and mortality among non-smokers, with NAT2 additionally significant for survival. Median, 25th percentile, and 75th percentile for the C-indexes based on the gene expression models are given in Table 1.

**Table 1. C-indexes for the Four Gene Expression Models Based on 1000 Test Data Sets**

Analysis of interaction between smoking status and gene expression values using the combined samples revealed significant interactions between smoking status and CYP1A1, LECT2, CETN1. Molecular signatures consisting of 7-8 genes were highly predictive for breast cancer recurrence and overall survival among smokers, with median C-index values of 0.8 and 0.73 for overall survival and recurrence, respectively. In contrast, the median C-index values for non-smokers was only 0.59. Hence, significant interactions between expression of crucial genes and cigarette smoking status appear to play a key role in predicting clinical outcomes of breast carcinoma patients. Supported in part by a grant from the Phi Beta Psi Charity Trust (TSK & JLW) and a Research of Women (ROW) grant to JLW from the EVP for Research and Innovation, University of Louisville.
Title: An academic cancer center’s experience in establishing a breast cancer-focused multidisciplinary genomic tumor board

Michelle McGowan¹, Shaveta Vinayak², Steven Maximuk², Roselle Ponsaran¹, Patricia Marshall¹, Lyndsay Harris² and Paula Silverman². ¹Case Western Reserve University, Cleveland, OH and ²University Hospitals Case Medical Center, Cleveland, OH.

Body: Background. Clinically, it is becoming increasingly important to assess genomic alterations in breast cancers using Next Generation Sequencing to find potential targets for personalized treatment. However, care paths for using such results to guide treatment have not yet been established. Previously reported studies suggest that developing an interdisciplinary review board to evaluate genomic findings can help to guide patient care. We report on a prospective qualitative study of a multidisciplinary genomic tumor board (MGTB) developed to discuss breast cancer patients’ genomic test results in the context of the clinical history and current practice guidelines. Our goal was to observe and describe the establishment of the MGTB and its members’ perceptions of a tumor board approach to interpreting genomic test results.

Materials and Methods. After IRB approval, we used qualitative case study methodology to study the MGTB and its participants, which include medical, surgical, and radiation oncologists, pathologists, geneticists, epidemiologists, bioinformaticians, pharmacologists, nurses, and bioethicists. MGTB meets on a monthly basis. Cases are anonymously presented by the treating physician. Genomic tumor findings from commercial vendors and in-house studies are discussed. Treatment recommendations are made by consensus, with level of evidence assigned based on Simon-Paik-Hayes biomarker guidelines. After obtaining consent from MGTB members, MGTB proceedings and interviews were recorded and transcribed for thematic analysis. Social dynamics within the MGTB, which includes interaction among MGTB members regarding interpretation and communication of genomic findings, were analyzed.

Results. MGTB began meeting monthly in 10/2013. As of 6/2014, 24 cases have been presented. All were female with metastatic breast cancer; 16/24 (67%) hormone receptor positive (ER or PR >1%), 7/24 (29%) triple negative, and 2/24 (9%) her2 positive. Analysis of meeting and interview transcripts revealed that though inherently multidisciplinary, the MGTB’s recommendations seem to be driven by medical oncologists with input from geneticists and pharmacologists when present. MGTB recommendations have become increasingly consistent over time. Based on genomic findings, the board often recommends referring patients to clinical trials (18/24, 75%) and to Medical Genetics (9/24, 38%) for evaluation of suspected germline abnormalities over other options such as drug therapies approved by the FDA for use in other tumor types.

Discussion and Conclusion. MGTB is a unique forum to discuss genomic test results and departs from typical tumor boards by involving non-clinicians. This case study suggests the feasibility of standardizing interdisciplinary evaluation and level of evidence recommendations for genomic results. The findings of this qualitative case study reveal MGTB members’ discomfort with recommending off-label use of FDA-approved therapies. Hence, on an institutional level, team dynamics will determine how testing and recommendations are established. Further study is required to assess institutional and professional variability in offering genomic testing and making treatment recommendations on the basis of genomic findings.
Title: Multiple breast cancer risk variants are associated with differential transcript isoform expression in tumors

Jennifer L Caswell¹, Scott Huntsman¹, Donglei Hu¹ and Elad Ziv¹. ¹University of California, San Francisco, San Francisco, CA.

Body: Introduction: Genome-wide association studies have identified over seventy single-nucleotide polymorphisms (SNPs) associated with breast cancer. A subset of these SNPs regulate expression of nearby genes, but the functional effects of the majority remain unknown. We hypothesized that some breast cancer risk SNPs may regulate alternative splicing of nearby genes. Methods: We used RNA sequencing data and matched germline genotypes from The Cancer Genome Atlas for 358 estrogen receptor (ER)-positive and 109 ER-negative breast tumors. For each risk SNP, we tested the association between genotype and exon-, junction-, and transcript-specific expression of genes within 500 kilobases, adjusting for overall gene expression. We excluded associations potentially related to error in mapping to pseudogenes or bias in mapping to the reference genome. Results: Six breast cancer risk SNPs were associated with differential isoform expression of seven nearby genes at FDR < 0.05 in ER-positive tumors; five of these associations replicated (P-value < 0.05) in ER-negative tumors (Table 1). At five loci, the pattern of association with alternative splicing mirrored the pattern of association with breast cancer. Of these five, two SNPs were associated with alternative splice site usage in nearby genes (STXBP4, BABAM1), one with exon skipping (DCLRE1B), and two with more complex exon usage patterns (PEX14, RAD51L1).

Associations between breast cancer risk SNPs and transcripts identified in ER-positive tumors at FDR < 0.05

Location is for hg19 build. β is for effect of the breast cancer risk allele. FDR is when all exon, junction, and transcript tests are considered together. P-values for ER- shown when < 0.05. * SNP is associated with transcript expression of two different genes. † Pattern of association with transcript does not correspond to pattern of association with breast cancer.

Conclusion: Regulation of differential transcript expression appears to be an important functional mechanism of breast cancer risk SNPs. These associations allow us to identify likely candidate causal genes, and also specific exons and transcripts that may mediate breast cancer risk, opening a new window into the link between risk variants, gene function, and outcome.
Title: Long range expression patterns detected by RNASeq in breast cancer reveal cluster enriched with triple negative breast cancer

Alex Mankovich1, Vartika Agrawal1, Nilanjana Banerjee1 and Nevenka Dimitrova1. 1Philips Research, Briarcliff Manor, NY.

Body: Background: Breast cancer subtyping using gene expression is well established in breast cancer research. While it is known that there are large chromosomal regions affected by copy number polymorphisms in breast cancer, it is not clear whether expression patterns reflect large genomic events affecting larger portion of the chromosome. We present a method to quantify long range gene expression patterns of larger genomic regions at 23kb, 100kb and 1mb.

Methods: We used TCGA-level 2 breast cancer gene expression data (RNA-Seq) generated at the Carolina Center for Genome Sciences, UNC at Chapel Hill. We evaluated the long range expression patterns of 649 patients for which we had ER, PR and Her2 status data by IHC. For 221 samples we had ER, PR, Her2, age, menopausal status, p53 and PIK3CA mutation status. Our method defines long range expression within a window of a particular length (e.g. 23kb, 100kb). We take the mean expression scores for all genes that fall within each window and concatenate these windows to obtain larger chromosome-wide patterns. The final chromosome-wide vectors are concatenated to represent long range expression patterns across the entire genome. We then evaluate the variation of these window scores across all samples and keep top 2% varying windows. Then, we apply hierarchical clustering, and evaluate enrichment of clinically meaningful subtypes using hypergeometric test.

Results: Simple hierarchical clustering revealed clear separation of triple negative breast cancer samples at any level of resolution: 23kb, 100kb in the available data set. While the 100kb resolution showed two distinct clusters, the 23kb resolution showed three distinct clusters. Interestingly, the hierarchical clustering of samples (n=649) using the top 214 (2%) highly varying long 100kb regions revealed a cluster which contained 99 samples and was enriched with 75 TNBC samples (out of 102 TNBC in the entire set) (p=1.7E-53).

The long range expression of 23Kb regions on 221 samples revealed 319 (2%) such regions which further segregate the samples into three different clusters: Cluster1: Luminal enriched cluster with 147 samples out of which 104 are ER+PR+Her2- samples (p-value <<0.01), Cluster2: Her2+ enriched cluster with 31 samples out of which 23 are Her2+ (p-value<<0.01), and Cluster3: TNBC enriched cluster containing 33 samples out of which 26 are TNBC (p=1.5E-18). There are a total number of 38 TNBC samples. Furthermore, in the TNBC cluster with 33 samples, 28 had p53 mutations and 24 of those were both TNBC and had p53 mutations (p-value << 0.05). In this TNBC cluster, there is enrichment of samples lacking PIK3CA mutations (n=31)(p-value <0.01). We found no clear association with age and menopausal status.

Conclusions: Hierarchical clustering relying on long range expression regions produces clusters that are enriched with well known clinically relevant subtypes. The associations with known tumor biology are strong for different region sizes (23kb and 100kb). This is the first study to report long range gene expression patterns that reveal data-driven close association with tumor biology.
Title: Re-assessment of 21-gene breast cancer assay utilization as a quality indicator by the Florida Initiative for Quality Cancer Care (FIQCC) Consortium

Christine Laronga¹, Weihong Sun¹, Erin Siegel¹, Ji-Hyun Lee¹, William J Fulp¹, Paul B Jacobsen¹ and Jhanelle E Gray¹. ¹H. Lee Moffitt Cancer & Research Institute, Tampa, FL.

Body: Background: In 2006, the FIQCC conducted a comprehensive review of quality of care indicators specific to breast cancer (BC) based on QOPI/NCCN/ACOS and panel consensus, with feedback provided on indicator performance to encourage quality improvement efforts. In 2009, at re-assessment of adherence to the previous indicators, we introduced a pilot quality indicator from the NCCN treatment guidelines: discussion/recommendation of the 21-gene BC assay for treatment decisions. The current study assesses quality improvement efforts targeting specifically the 21-gene BC assay.

Methods: After disclosure of results in 2012, 5 FIQCC sites agreed to participate in a re-assessment sub-study focused on the 21-gene BC assay. Following IRB approval, each site developed and implemented a site-specific quality improvement plan focused on the discussion/utilization of this assay. Following this intervention, chart reviews were conducted for ER+ BC patients first seen by a medical oncologist in 2013 and eligible for the 21-gene BC assay based on NCCN criteria (n=130). Data collected included: 1) documentation of a discussion with the patient of the 21-gene BC assay; 2) documentation of ordering/performance/results of the 21-gene BC assay; and 3) treatment decisions based on results and/or documentation of reasons for non-compliance. Statistical comparisons of the previously collected 2009 data (n=262) for these 5 FIQCC sites and new 2013 data were performed using the Pearson Chi-Square exact test based on Monte Carlo estimation.

Results: Overall, the mean age of patients was 62 years (range 30-89) for the combined 2009 and 2013 years. More women had her2 negative BC in 2013 compared to 2009 (p=0.003). Since the 2009 dataset was not specific to the 21-gene BC assay eligibility, a smaller proportion of patients had tumor sizes staged as T1c/T2/T3 [80.3% vs. 92.2% for 2009 as compared to 2013, p=0.005] and less were node negative in 2009 [56.8% vs. 96.6%; p<0.001]. Based on NCCN criteria, only 60.9% of eligible patients had a documented discussion or recommendation for the 21-gene assay in 2009 with significant variability among the 5 sites (p=0.011). A significant improvement was seen in 2013 (p<0.001) with 91.4% of eligible patients having documentation of a discussion or recommendation for the 21-gene assay without significant variability amongst the practice sites. Significant improvement in the percentage of patients having the assay ordered from 2009 to 2013 was seen (p<0.001) but variability amongst the sites persisted (2009: p=0.002; 2013: p=0.018). Recurrence Score (RS) results were completely recorded in both 2009 and 2013. All patients with high-risk RS were referred for chemotherapy. A small fraction of patients with low-risk RS was referred for chemotherapy both years (2009: 5.4%, 2013: 3.8%; p=1.00).

Conclusions: Previously, the FIQCC identified quality improvement needs in multiple aspects of BC care, including recommendation and ordering of the 21-gene BC assay. A dedicated quality improvement effort can significantly increase both the discussion/recommendation and ordering of the 21-gene BC assay among eligible patients. These improvements have the potential to alter treatment recommendations.
Title: Examining 3-dimensional genome architecture and transcriptional profiles using an optimized HiC-seq protocol in breast cancer cells

Jennifer D Davis¹, Christian Ross², Hu Li² and Amy Brock¹. ¹University of Texas, Austin, TX and ²Mayo Clinic, Rochester, MN.

Body: The post-genomic era ushered in a cadre of techniques to study epigenetic mechanisms involved in disease progression and cancer. One understudied mechanism of gene expression/transcriptional control is 3-dimensional architecture of the genome. Several high-throughput technologies have been adapted to examine 3D genome architecture; in particular those derived from chromatin conformation capture (3C) sequencing technologies. Of 3C-derived techniques, HiC-seq, is the most extensive, and examines all chromatin-chromatin contact sites within a genome, elucidating the entire 3D genome architecture. Although, HiC-seq technique was published 2009, it has been under-utilized in research laboratories due to its technical complexity, expense, and requirement for large volumes of starting material (50 million cells/500 µg of DNA). Other barriers to use of HiC-seq include the requirement for specialized equipment and laborious extraction techniques. However, the benefits of HiC-seq are high for cancer researchers because a genome-wide "snap-shot" of the entire 3D genome of the cancer is displayed. This allows for analysis of higher-order epigenetic control of gene expression. Furthermore, understanding the chromatin conformation of the genome provides new insights into the cellular disease state and potentially novel therapeutic approaches to drug-resistant cancers. Our study presents significant technical innovations, permitting HiC-seq technique to be adopted in laboratories without extensive experience in 3C-seq technologies, and with the use of standard equipment and reagents, as well as smaller volumes of starting materials. Our modified technique utilizes up to 100 fold lower amounts of starting material (500,000 cells/5-10 µg of DNA) per reaction. This adaptation of HiC-seq preparation offers the potential for simultaneous extraction of total RNA and Hi-C processed chromatin for sequencing. To optimize our technique we utilized the estrogen-responsive breast cancer cell line, MCF7. This cell line is typically utilized to study potential drug therapies in the context of estrogen-sensitive cancers. We streamlined HiC-seq by optimizing nuclei extraction and allowing for collection of a cytoplasmic fraction for mRNA extraction and sequencing analysis. We also optimized enzymatic digestion, ligation and DNA extraction methods by utilizing newer enzymatic chemistries, commercially available silica column extraction methods and reagents in place of multiple phenol-based DNA extraction methods. Our quality control results suggest that sample processing for reduced amounts of material is similar if not superior to conventional HiC-seq. We leverage this powerful genomic high-throughput technique in order to simultaneously examine the 3D architecture and transcriptional profiles of MCF7 breast cancer cells. Our computational workflow includes further quality controls using HiC-User Pipeline software from the Bahraham Institute and the R Bioconductor package HiTC package. Overall our optimizations in MCF7 breast cancer cells, and post-acquisition work-flow, make HiC-seq an accessible technology. These innovations permit simultaneous analysis of architectural and transcriptional profiles in cancer cells.
Title: Assessing reproducibility of copy number arrays to assist breast cancer biomarker discovery

Cindy Q Yao1, Cheryl Crozier1, Mary Anne Quintayo1, Jane Bayani1, Melanie Spears1, Julie Livingstone1, Esther Jung1, Clement Fung1, Victoria Sabine1, Paul C Boutros1 and John MS Bartlett1. 1Ontario Institute for Cancer Research (OICR), Toronto, ON, Canada.

Body: Introduction:
Large-scale interrogation of the genome has emerged as an attractive method for identifying useful characteristics of cancer biology; in particular, the study of copy number aberrations (CNA) has recently received tremendous attention. A number of different technologies have been developed to assess the copy-number landscape, allowing us to better understand the role of CNA in cancer cells. The OncoScan CNA platform (Affymetrix Inc.) has been particularly appealing for oncology due of its ability to work well with formalin-fixed, paraffin-embedded (FFPE) materials, which is the primary form for storage of clinical samples. In addition, its high resolution, rapid analysis time and ability to interrogate different genomic characteristics (CNA, loss of heterozygosity or mutation) make the OncoScan platform highly popular: it has been widely cited in the literature for use in biomarker discovery, clonal evolution and sub-clonal detection, as well as population-based analyses. While CNAs identified by the OncoScan platform have shown good concordance with fluorescence in-situ hybridization (FISH) results, to date, no studies have been conducted to thoroughly assess the reproducibility of the assay. In this study, we have assessed the reproducibility of the OncoScan platform using identical samples performed in replicates across multiple chip batches. Moreover, we have assessed the effect on reproducibility of DNA treatment, including elution in water or TE buffer, as well as in the use of varying amounts of DNA.

Methods:
Affymetrix OncoScan FFPE Express 3.0 SNP Arrays were performed using the optimal input DNA as recommended by the manufacturer as well as fewer input amounts for comparison. CNAs were called using BioDiscovery Nexus Copy Number™ software (http://www.biodiscovery.com/software/nexus-copy-number/) using the SNP-FASST2 algorithm with modified parameters (significance threshold of 1 x 10^{-9} and minimum number of probes per segment of 10).

Results:
Initial reproducibility analysis involving 12 samples repeated either 2, 4 or 6 times both within a single batch and across different batches has revealed that CNA calls were concordant between replicates for the majority of the genome (ranges between 81% to 100%), suggesting high precision of the assay. In addition, we are in the process of assessing and comparing mutation calls across replicates to gain a more in-depth understanding of the platform.

Conclusion:
This is the first study examining the reproducibility of OncoScan FFPE assays; initial results have suggested that the assay is precise and has the potential for robust biomarker discovery. Additional characterizations would be interesting for evaluating its use as a clinical tool in the long term.
Discovery of novel amplified genes in primary breast cancer with copy number and gene expression analysis of whole exome and transcriptome sequencing data

Eunshin Lee¹, Woosung Lim¹, Kyung-Min Lee¹, Tae-kyung Yoo¹, Jongjin Kim¹, Han-Byoel Lee¹, Yun-Gyoung Kim¹, YoungJoon Kang¹, Min Kyoon Kim¹, Hyeong-Gon Moon¹, Dong-Young Noh¹ and Wonshik Han Han¹. ¹Seoul National University College of Medicine, Seoul, Korea.

Body: Introduction: Copy number alteration of genome is common in breast cancer and tend to have more driver role than single point mutations. Traditionally, genome-wide analysis of DNA copy number changes were done by array CGH or SNP array method. Here, we did DNA whole exome sequencing (WES) and RNA-seq using Next Generation Sequencing (NGS) technology to find common genes or chromosomal regions of which DNA copy was highly amplified and at the same time RNA expression was also upregulated.

Materials and Method: RNA and DNA were extracted from fresh frozen tissues of 93 breast cancer patients. WES and RNA-seq were done using NGS technology (Illumina HiSeq 2000). As a control, normal DNA from all matched patients were also sequenced. GATK was used to gain mean depth and coverage data for targeted regions. CNVs were calculated with ExomeCNV, a statistical method to detect somatic CNVs using depth-of-coverage information from mapped short sequence reads. To estimate expression levels, the relative transcript abundances were measured in FPKM using Cufflinks.

Results and Discussion: DNA of 1,737 genes were highly amplified (log R>1.0) in two or more samples. The two most commonly amplified chromosomes were chromosome 8 and 17. We applied a cut-off for higher gene expression as relative FPKM >1.5. ERBB2 amplifications and high expression were most common (21.5%) of all genes and it was in agreement with HER-2 IHC and FISH result. Among previously reported amplified genes, FGFR1 (5.4%) and PVT1 (8.6%) in chromosome 8, CCND1, PAK1 (3.2%) and EMSY (4.3%) in chromosome 11, CCNE1 (4.3%) in chromosome 19 were also identified in this study. IGF1R high amplification and expression was found in two samples, and ESR1, MDM2, KIT was found in only one sample each. We found uncommon but novel and recurrent highly amplified and expressed genes: CLK4 in 5q (3.2%), AHI/MYB in 6q (3.2%), MMP7(2.2%) and MALAT1 in 11q (1.1%), and NEK8 in 17q (4.3%) We designed FISH probe for this 5 new genes and confirmed the high amplifications in each sample with FISH. Functional study of these genes will be followed for the driver role of these genes in carcinogenesis and progression of breast cancer cells.
Title: Discovery of the genes that underpin the transition to malignant phenotype of breast tumors in highly consanguineous region

Ishita Gupta¹, Allal Ouhtit¹, Somya Shanmuganathan¹ and Hamad Al-Riyami¹. 'Sultan Qaboos University, Muscat, Seeb, Oman.

Body: Breast cancer (BC), a multifactorial and heterogeneous disease is a predominant women form of cancer worldwide affecting 22.9%. The rationale of this study is based on the following observations: 1) in Oman, a significantly increasing number of younger females (25-40 years) present to the clinic with advanced stage of BC; 2) in Oman, the rate of consanguinity is significantly high (52%); and 3) the transition from normal/beginin to malignant phenotype of breast tumor requires the involvement of a subset of specific genes. The long-term objective of this study is to identify and validate the subset of genes that are responsible for this malignant transformation using functional genomic studies, focus on this young age group of patients attending BC clinic (sporadic and familial). RNA samples were isolated from 40 Breast Tumors and 40 Normal tissues and analyzed by Microarray Gene Expression Profiling. Among a number of genes that were up and down regulated, BRIP1, HOXB3 and MAGED1 were identified as potential genes that might underpin the transition to the malignant phenotype; these genes were validated by RT-PCR using the same RNA samples that were examined by microarray. Pathway analysis was carried out to identify the major functional pathways connecting these genes. Ongoing sequencing of these genes using DNA extracted from the same samples will ultimately identify any genetic alteration that can affect the normal function of these genes. Functional validation assays aim to validate further the physiological relevance of these genes in tumor malignancy, and perhaps other novel genes specific to BC in the Omani population. Identification and validation of these genes will potentially pave the way towards the design of anti-cancer therapeutic strategies.
The signal transduction molecule MAP3K12 is critical for triple-negative breast cancer cells

Graham M Poage, Abhijit Mazumdar, Ivan P Uray, Jamal Hill, Yun Zhang, Gordon B Mills and Powel H Brown. 1University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Background: Mitogen-activated protein kinase kinase kinases (MAP3Ks) are critical network hubs in signal transduction pathways that control many cellular responses including growth, inflammation, differentiation, apoptosis, and development. Recently, MAP3Ks have been implicated in the early and metastatic progression of solid tumors, including breast cancer. While some estrogen receptor (ER)-positive breast cancers have deletions or loss-of-function mutations in MAP3K1, consensus genetic alterations in triple receptor-negative breast cancers (TNBCs) have not been described for these important signal transduction molecules. Among the clinical subtypes, TNBCs carry the worst prognosis and no targeted interventions have yet been approved for routine use. Therefore, we sought to systematically determine which MAP3Ks are required for the growth of TNBC cells to discover novel targets for the treatment of this aggressive disease.

Materials and Methods: To determine which MAP3Ks are specifically required for proliferation of TNBC cells, we performed an RNAi screen by reverse transfecting siRNA pools targeting each of the 22 MAP3Ks (and the control Luciferase) across 5 triple-negative and 5 ER-positive breast cancer cell lines and measuring growth after 6 days. Candidate siRNAs that preferentially inhibited TNBCs were advanced to a secondary anchorage-independent growth screen to determine their ability to inhibit colony formation in soft agar. We developed doxycycline-inducible shRNA-expressing stable cell lines to determine whether the MAP3K is required for the growth of xenograft tumors in nude mice. Explanted xenograft tumors were analyzed by immunofluorescence for cleaved caspase-3 and immunohistochemistry for Ki-67. To determine how growth is inhibited by the candidate siRNAs, we performed FACS and immunoblot analysis to assess apoptotic initiation as well as cell cycle and thymidine-analogue incorporation experiments to determine proliferative dynamics.

Results: We identified multiple MAP3Ks, including MAP3K3, MAP3K4, MAP3K12, and MAP3K17, which were necessary for the growth of two or more TNBC cell lines but not more than one ER-positive cell line. Knockdown of these genes were also required for soft agar colony formation of TNBC cell lines. Further, knockdown of MAP3K12 in nude mouse xenografts significantly inhibited their growth rate and correlated with a decrease in Ki-67-positivity. In vitro experiments demonstrated that inhibition of cell proliferation is a result of an increased persistence of cells in the G0/G1-phase, evident by decreased thymidine-analogue incorporation and cell cycle analysis, and is not due to alterations in apoptotic activity.

Discussion: This study identified MAP3Ks that are required for the growth of specific breast cancer cell lines, specifically TNBCs. No one MAP3K is critical for the growth of all TNBC cells. Instead, different TNBC tumor cells utilize distinct MAP3Ks for their growth. These data support the development of inhibitors targeting specific MAP3K proteins, particularly MAP3K4, 12, and 17, for the treatment of women with TNBC.

This study was supported by a grant from the Breast Cancer Research Foundation (P.B.) and a Susan G. Komen for the Cure Promise Grant (P.B., G.M., KG081694).
Title: Identifying molecular targets and mechanisms of treatment resistance in inflammatory breast cancer (IBC) using reverse-phase protein microarrays (RPMA)

Laura Austin¹, Kimberly Limentani¹, Juan Palazzo¹, Tiffany Avery¹, Rebecca Jaslow¹, Ron Hencin³, Emanuel F Petricoin²,³ and Massimo Cristofanilli¹,⁴. ¹Thomas Jefferson University Hospital, Philadelphia, PA; ²George Mason University, Fairfax, VA; ³Theranostic Health, Inc, Rockville, MD and ⁴Inflammatory Breast Cancer International Consortium.

Body: Background
Inflammatory Breast Cancer (IBC) is a clinicopathologic diagnosis characterized by rapid progression and poor prognosis. Even with the advent of targeted therapies and a multimodal approach, IBC is often treatment refractory and a therapeutic challenge for all subtypes, including ER+ and HER-2 amplified (HER2+) disease (Masuda et al). Therefore identifying mechanisms of resistance to molecularly targeted therapy could provide clues to improve management and outcome. Recent studies comparing the gene expression profiles of IBC tumors with non-IBC demonstrated that HER2+ IBC have increased mTOR signaling compared to their non-IBC counterparts (Iwamoto et al). mTOR activation is a mechanism for Trastuzumab resistance and may contribute to treatment resistance in HER2+ IBC. The availability of molecular diagnostics evaluating phosphoproteins is an appealing approach to predict treatment-sensitivity and select more effective combinations.

Methods
This is an observational analysis of 12 IBC patients who had tissue biopsy after progression on standard therapies including HER-2 targeted therapies. Tissue analysis for expression of cancer-related phosphoproteins was performed using TheraLink™. The TheraLink™ assay uses reverse-phase protein microarrays (RPMA) to quantify HER1, HER2, and HER3 receptor overexpression; it also evaluates for phosphorylation of the receptor which indicates activation. Phosphorylation of HER downstream signaling pathways such as JAK2, AKT/mTOR and MEK1/2 are also detected. Additionally, next generation sequencing (NGS) using FoundationOne™ was performed if sufficient tissue was available.

Results
All patients had IBC and most had metastatic disease (83%). According to subtype 25% of patients were ER+/HER2-, 42% ER+/HER2+, 25% ER-/HER2+, 8% ER-/HER2-. 58% of tumors demonstrated HER1 activation, 75% had HER2 activation and 58% had HER3 activation. Interestingly, 83% had mTOR activation, and most of these patients also had accumulation of its downstream proteins, S6 ribosomal protein and 4E-BP-1. 78% of patients with HER2 activation also had mTOR activation. Two of the 4 patients who were HER2- by IHC/FISH had HER2 activation by RPMA. Six patients also had NGS on tissue; 75% had concordance between HER2 activation on TheraLink™ and ERBB2 amplification on NGS, 67% had concordance with mTOR activation on TheraLink™ and mutation in the mTOR pathway (PIK3CA mutation or PTEN loss) on NGS. One patient with triple negative, chemo-refractory IBC who underwent 3 lines of neoadjuvant therapy prior to bilateral mastectomy was found to have HER1, HER2, HER3 and mTOR activation; she was started on lapatinib and capecitabine and remains with no recurrent disease and on treatment.

Conclusions
Patients with IBC often have activation of members of the HER family and mTOR pathway indicating molecular targets and potential mechanisms of resistance in IBC. The concomitant use of NGS and RPMA is an intriguing approach to molecular diagnostics in this aggressive and treatment refractory disease providing additional information on pathway activation leading to expanded therapeutic options. Future prospective studies should clarify the potential impact in treatment selection and outcome.
Title: Circulating tumor DNA (ctDNA) provides molecular monitoring for inflammatory breast cancer (IBC)

Laura Austin¹, Paolo Fortina¹, Dragan Sebisanovic², LaiMun Siew², Aubrey Zapanta², Benjamin J Schiller², Gangwu Mei², Helmy Eltoukhy², AmirAli Talasaz³ and Massimo Cristofanilli¹,³. ¹Thomas Jefferson University Hospital, Philadelphia, PA; ²Guardant Health, Inc, Redwood City, CA and ³Inflammatory Breast Cancer International Consortium.

Body: Background
Inflammatory Breast Cancer (IBC) is a clinicopathologic diagnosis characterized by rapid progression, resistance to treatment and poor prognosis. It is often an incurable disease with complex molecular features including somatic mutations that evolve in relation to genomic instability and selective treatment pressure. Monitoring disease by performing multiple biopsies may not be feasible and puts the patient at risk with each invasive procedure. Circulating DNA fragments carrying tumor-specific sequence alterations (ctDNA) are found in blood and offer the possibility of longitudinal non-invasive molecular monitoring of the disease by detecting actionable mutations.

Methods
This is an observational analysis of 35 IBC patients who failed standard therapies and had plasma analyzed for ctDNA detection. Selection criteria included progression of disease after standard therapies, need to detect novel molecular abnormalities for possible therapeutic targeting, or confirmation of genomic abnormalities already demonstrated in tissue analysis. Guardant Health performed the plasma analysis (Guardant360®); first ctDNA was isolated from plasma, then a panel of 54 gene mutations associated with solid tumors as reported in the COSMIC database were sequenced to concurrently analyze somatic mutations and gene amplification using single-molecule digital sequencing technology.

Results
All patients had IBC and 80% had metastatic disease; 37% of patients were ER+/HER2-, 14% ER+/HER2+, 23% ER-/HER2+, and 26% ER-/HER2-. 94% of patients with stage III or IV tumors had ctDNA alterations detected. The most common mutations were TP53 (49%), PIK3CA (20%), ERBB2 (17%), NOTCH1 (17%), and ALK (11%). Twelve patients also had next generation sequencing (NGS) analysis of tissue biopsy and 75% of these patients demonstrated at least one concordant mutation. The genomic information obtained from ctDNA, NGS or both was used to select treatments in 11 cases (31%). HER2 targeted therapy was continued in four patients with HER2+ disease after ctDNA confirmed ERBB2 alteration or amplification. A patient with ER+/HER2+ disease who progressed on HER2 targeted therapies, demonstrated ERBB2 and PIK3CA mutations on ctDNA; she was changed to exemestane/everolimus with objective response for several months. Repeat ctDNA at time of progression showed ERBB2 mutation only; she was changed to Trastuzumab/everolimus/vinorelbine. Moreover, a combination of lapatinib and capecitabine was initiated on a patient with a triple negative, chemo-refractory tumor that on ctDNA revealed EGFR and ERBB2 mutations; a repeated ctDNA after 5 months of therapy EGFR and ERBB2 mutations were not detected and she remains without evidence of progression.

Conclusions
Evaluation and longitudinal monitoring of IBC patients using ctDNA allows for identification of genomic abnormalities in all patients with advanced disease and to perform real-time molecular monitoring. The discovery of actionable genomic abnormalities is driving the management of this aggressive and treatment refractory form of breast cancer with potential future impact on outcome.
Body: Background: While mammographic density is linked to increased breast cancer risk, limited yet conflicting data exists on an association between density and developing specific molecular subtypes of breast cancer.

Methods: Eligible patients were enrolled in a larger study on breast density, diagnosed with cancer between 2003-2013, and had pathology and films available for review. Density was classified qualitatively from existing radiology reports according to Breast Imaging Reporting and Data System (BIRADS) classification and quantitatively by volumetric breast density measurements using Volpara Solutions™ software. Subtype was assigned by hormone receptor status, tumor grade and mitotic score (MS). Subtype categories included: Luminal A (ER/PR + & grade 1; ER/PR + & grade 2 & MS=1; ER+/PR- & grade 1); Luminal B (ER+ & grade 3 or MS=3; ER+/PR- & grade 2; ER/PR + & grade 2 & MS=2); Her-2 + (ER+ or ER - & Her-2 +); Triple Negative (ER/PR-, Her-2 -). Relevant pre-cancer factors including patient age, race, BMI, family history of breast cancer, and biopsy showing LCIS were included in analysis.

Results: Of 604 patients with invasive cancer, 457 had sufficient information for analysis. Among these, 233 (51%) had Luminal A, 79 (17%) Luminal B, 59 (13%) Her-2 +, and 86 (19%) Triple Negative tumors. Younger women and those with denser breasts based on quantitative measurements were more likely to have Her-2+ tumors (Table 1); this association was not seen using the standard BIRADS classification. Triple Negative tumors were less common in patients with LCIS and more common in African Americans. A multinomial logistic regression model controlling for pre-cancer patient factors demonstrated that while quantitative breast density does not significantly differentiate between all molecular subtypes (p=0.140), the association between Her-2+ tumors and denser breasts using continuous quantitative measurements is significant (p=0.035).

Conclusion: Women with denser breasts by continuous-scaled quantitative measurements are at higher risk for Her-2+ tumors; an association not delineated using standard BIRADS density classification. Delineating risk factors specific to molecular breast cancer subtype may promote individualized risk prediction models and prevention strategies.

Title: Modeling luminal breast cancer heterogeneity: Combination therapies to suppress hormone receptor-negative subpopulations among receptor-positive ones

Allison L Scaling, Aaron J Knox, Mauricio P Pinto, Brian S Bliesner, James M Haughian, Hany A Abdel-Hafiz and Kathryn B Horwitz. 1University of Colorado Anschutz Medical Campus, Aurora, CO.

Body: All Luminal breast cancers are heterogeneous, containing substantial numbers of estrogen (ER) and progesterone (PR) receptor-negative cells among the ER+PR+ ones. We have identified two such Luminal-derived ER–PR– cells: The first, we call "Luminobasal" (LB), are ER–PR– and cytokeratin 5 (CK5)-positive. The second, we call "Double Negative" (DN), are ER–PR– and CK5–. Currently, neither is targeted for treatment. Luminobasal cells: To address the relationships between true Luminal ER+PR+CK5– and Luminobasal ER–PR–CK5+ cells in Luminal cancers and tightly control their ratios we generated isogenic pure Luminal (pLUM) and pure Luminobasal (pLB) cells from solid tumor xenografts starting from the same parental T47Dco Luminal human breast cancer cell line. Cells were gene profiled and unique immunohistochemical (IHC) biomarkers for each were confirmed. Interaction dynamics studies show that in mixed-cell 3D colonies, pLUM or Luminal MCF-7 cells suppress growth of pLB cells. Similarly, in mixed-cell solid tumor xenografts, pLUM cells suppress pLB proliferation. Alarming, in mixed-cell models, monotherapy of a pLUM or MCF-7 subpopulation with the antiestrogen Fulvestrant inadvertently expands the number of pLB cells. This suggested that pLB cells also need to be treated. An 89 drug FDA-approved oncology library and high throughput screening methods were therefore used to show that pLB cells are specifically targeted by the EGFR inhibitors Gefitinib and Erlotinib. We then showed, in both mixed-cell 3D colonies and mixed-cell solid mouse tumors, that combination therapy using Fulvestrant plus Gefitinib constitutes a robust treatment strategy that targets both cell populations simultaneously. Double Negative cells: DN cells are EGFR– and therefore unaffected by EGFRi. However they express the Luminal marker Claudin-3 (CLD3). Among other conditions, DN cells arise as a discrete CLD3+ subpopulation within CLD3– pLB xenografts. This allowed us to use CLD3 for FACS isolation and purification of DN cells from xenografts. Purified cells were gene expression profiled, which showed that DN cells have a unique genomic signature that distinguishes them from LUM and LB cells. They express diagnostic markers suitable for IHC and FACS-sorting, some of which also present potential therapeutic targets. We propose that heterogeneous Luminal breast cancers may be best treated with combination therapies that include endocrine, EGFRi and/or DN inhibitors. Importantly, optimizing combination regimens that eradicate or suppress not only ER+PR+ cells but also diverse ER–PR– cells in Luminal disease requires that primary tumors be pre-screened for appropriate biomarkers, including but not limited to ER, PR, CK5 and EGFR.
Demonstration of immune cell and pathway heterogeneity in Singapore DCIS samples using novel hyperplexing method (MultiOmyx®)

Nicole E LaPlante¹, Yunxia Sui¹, Michael J Gerdes¹, Sean Dinn¹, Rong Zhang¹, Sireesha Kaanumalle¹, Elizabeth McDonough¹, Christina Lowes¹, Craig Allred², Fiona Ginty¹, Thomas Foo¹ and Puay-Hoon Tan³. ¹GE Global Research, Niskayuna, NY; ²GE Healthcare, Aliso Viejo, CA and ³Singapore General Hospital, Singapore, Singapore.

Breast cancer is the most common malignancy in Singapore women with rising incidence across all ethnic groups (Chinese, Malays and Indians). Ductal carcinoma in situ (DCIS) is the earliest non-invasive stage of disease and has been shown to account for approximately 26% of diagnoses in all women participating in the Breast-Screen Singapore program. Despite availability of breast screening, there are still Singapore women presenting with locally advanced breast cancer. The goal of the current study was to investigate pathway and immune cell heterogeneity in low, intermediate and high nuclear grade DCIS using a newly developed method for in situ hyperplexed analysis of multiple proteins in a single FFPE tissue (MultiOmyx). FFPE samples from patients (n= 15) diagnosed with DCIS were provided by Singapore General Hospital. Patients were of Chinese origin, ranged from 50-59 years, were all post-menopausal, and included low (n=5), intermediate (n=5) and high grade (n=5) samples. All histological diagnoses were reviewed by a single pathologist. Following a single antigen retrieval step, DAPI and cytokeratin staining was conducted and imaged at 10X. Based on DAPI, cytokeratin and autofluorescence, an H&E-like image was generated for each sample. Using this image, approximately 30 regions of interest (ROI) were selected per slide/patient, including normal and DCIS regions with and without immune cells. In total, 15 biomarkers were imaged following an iterative process of IF staining and dye inactivation. These included CD4 (T-cells), CD8 (T-cells), CD20 (B-cells), CD68 (macrophages), CD10 (myoepithelial cells), CD44v6 (cancer stem cell), Her2, Her4, EGFR (ErbB family proteins), pmTOR (cell growth), SLC7A5 (Mammostrat) and epithelium and cell segmentation markers (pan-cadherin, pan-cytokeratin, S6 and Na+K+ATPase). Images were evaluated for quality and processed to generate single cell quantification data for each marker in the epithelium and stroma. Single cell data was compared with clinical and histological features (grade, DCIS/ low immune cells, DCIS/ high immune cells). Cell-based k-means clustering was then performed for biomarkers in both the epithelial cells (Her4, Her2, panCK, SLC7A5, EGFR, NaKATPase, pmTOR, and CD10) and stromal cells (CD4, CD8, CD20, CD68). Using consensus clustering, the optimum number of clusters was found to be six in both the epithelium and stroma. No distinct clusters were associated with histological grade. Normal ROIs tended to be associated with higher CD10 and EGFR, moderate CD20 and low or negative for other markers. DCIS with low immune cells tended to have higher Her4, pmTOR and moderate CD68 while DCIS with high immune cells tended to have high Her2 and moderate to high CD4, CD20 and CD68. A larger study is needed to associate the findings with outcome. This technology provides a way to elucidate mechanisms of early disease and illustrates the complex inter-play between grade, pathway activation and immune response.
Body: BACKGROUND
Recently, it has been shown that annotation of triple-negative breast tumours (TNBC) by means of immunohistochemistry (IHC) or gene-expression signatures (GES) gave different results: 20 to 30% of these tumours were not basal-like, but luminal A, B or HER2-E. In this study, we aimed at identifying gene-expression molecular subclassification of IHC-TNBC.

MATERIALS AND METHODS
Patients
Studied bi-centric cohort retrospectively included 107 randomly selected women whose primary breast tumours lacked IHC expression of estrogen receptor, progesterone receptor and HER2. Patients were diagnosed and treated primarily between 1998 and 2007 at the ICO-Gauducheau (n=65) and the ICO-Papin (n=42).

Gene expression profiling
Gene expression analysis was performed using Affymetrix Human Genome U133 Plus 2.0 Arrays that correspond to approximately 20,000 genes.

Statistical analysis
Unsupervised analysis was performed by means of fuzzy clustering. Independent IHC-TNBC cohort (GSE21653; n=87) was used for external validation.

"Fuzzy cluster“ functional annotation
To annotate “fuzzy-clusters”, we used clinicopathologic characteristics, gene-expression signatures (GES) (PAM50, Proliferation score, TNBCtype, Immune response, Claudin-low), Gene Ontology enrichment and IHC (CK5, CK5/6, HER1, AR, Ki-67, FOXA1).

RESULTS
Fuzzy clustering partition individualized 3 clusters in our cohort: C1, C2 and C3. “Fuzzy cluster“ functional annotation results are displayed in Table 1. C1 was composed of a mixture of non-basal-like subtypes. C2 and C3 were basal-like and IHC-TNBC. Except an adenoid cystic case, C2 was exclusively composed of basal-like subtypes. C3 was essentially characterized by immune response and included 26% of claudin-low subtypes. For this reason, C3 should rather be named “immune response cluster“. External validation confirmed our results.

### CONCLUSION

Heterogeneity within basal-like and IHC-TNBC is still controversial and require further research to understand the complexity of the disease, and to identify molecular drivers that can be therapeutically targeted. Annotation discordances between IHC and GES clearly indicate that a robust molecular subtyping method must be found. Correct molecular assignment would permit to orientate 20 to 30% of IHC-TNBC patients towards targeted therapy (hormonotherapy or anti-HER2).

Title: Accuracy of estrogen receptor, progesterone receptor, HER2 Status and Ki67 labeling index between core needle and surgical excisional tumour in 910 patients with breast cancer

Rikiya Nakamura, Naohito Yamamoto, Yoshiyuki Itookubo, Ayako Nakagawa and Makiko Itami. Chiba Cancer Center Hospital, Chiba, Japan.

Body: Purpose
Accurate determination of ER, PgR, HER2 status and Ki67 labeling index was very important in making decision for adjuvant and neoadjuvant treatment for patients with breast cancer. However discordance of ER, PgR, HER2 status and Ki67 labeling index (Ki67-LI) between core needle biopsy (CNB) and surgical specimens (SSp) varied among reported studies. The aim of the present study was to compare the accuracy of CNB with that of SSp for ER, PgR, HER2 status, Ki67-LI detection in breast cancer.

Patients and methods
All patients diagnosed with an early breast cancer in our Cancer Center Hospital between January 2005 and May 2014 was included but exclusion criteria of patients with large tumour requiring neoadjuvant chemotherapy. All CNB were performed under ultrasound guidance, with at least four 14-gauge core biopsies being obtained for pathological examination. ER, PgR, HER2 status and Ki67-LI were assessed in CNB and in SSp. ER and PgR were determined by Immunohistochemistry (IHC). The cut points for ER and PgR positive was10%. The cut point for Ki67-LI high expression was 20%. HER2 was determined by IHC and scored from 0 to 3+. FISH analysis was carried out in HER2 2+ cases and in discordant cases.

Results
A total of 910 patients were assessed. CNB can be used with confidence for ER and HER2 determination. Rates for sensitivity, specificity, negative predictive value and positive predictive value for CNB compared with SSp are 99.3%, 95.6%, 97.2%, 98.5% for ER, 94.5%, 81.8%, 88.2%, 90.7% for PgR, 93.0%, 99.1%, 99.6%, 93.9% for HER2, and 87.7%, 69.8%, 81.1%, 79.4% for Ki67-LI, respectively. Specially, the most impact factor of discordance for Ki67-LI and HER2 is Tumour size and that for ER and PgR is lobular carcinoma.

Conclusion
CNB can be used with confidence for ER and HER2 determination. For PgR and Ki67-LI due to substantial discordance results from CNB should be used with caution.
Title: Utility of simultaneous HER2 protein and gene assessment for the evaluation of discrepancy and intratumoral heterogeneity of HER2 status and the prediction of prognosis in invasive breast cancer using the gene-protein assay (GPA)

Sasagu Kurozumi¹, Mary Padilla², Masafumi Kurosumi³, Hiroshi Matsumoto¹, Yuji Hayashi¹, Katsunori Tozuka¹, Shigenori E Nagai⁴, Kenichi Inoué⁴, Hanako Oba⁵, Jun Horiguchi⁶, Izumi Takeyoshi⁶, Jim Ranger-Moore², Eslie Dennis² and Hiroaki Nitta².
¹Saitama Cancer Center, Saitama, Japan; ²Ventana Medical Systems, Inc, Tucson, AZ; ³Saitama Cancer Center, Saitama, Japan; ⁴Saitama Cancer Center, Saitama, Japan and ⁵Gunma University Graduate School of Medicine, Gunma, Japan.

Body: Background:
The eligibility of patients for HER2-targeted therapies is determined by the evaluation of HER2 gene amplification and HER2 protein overexpression. The gene-protein assay (GPA, Ventana Medical Systems, Inc., USA) is a new method for simultaneous evaluation of HER2 immunohistochemistry (IHC) and dual in situ hybridization (DISH) using a single tissue section. In this study, we investigated the relationship between HER2 IHC and DISH results evaluated by GPA. In addition, we analyzed the correlation between HER2 status and prognosis of invasive breast cancer patients.

Patients and Methods:
In this study, invasive carcinoma tissues of 280 consecutive patients treated in Saitama Cancer Center in 2000-2001 (median follow-up: 130 months) were examined. Among HER2 positive initial samplings, no patients originally received adjuvant trastuzumab therapy. However, 76% of HER2 positive cases of recurrence received trastuzumab therapy. GPA was performed on a section of routinely processed primary tumor and the status of HER gene and protein were separately evaluated in whole areas of tumor sections using the following FDA criteria: DISH (negative: HER2/CEN17 < 2, positive: HER2/CEN17 ≥ 2.0) and IHC (score 0 to 3+). In IHC score 2+ patients group, final HER2 positivity was decided according to DISH results using criteria of FDA criteria. Recurrence-free survival (RFS) and cancer-specific survival (CSS) stratified by IHC and DISH results were analyzed. In addition, patterns of heterogeneity were grouped according to the following 4 phenotypic and genotypic types: A) IHC 2+/DISH+; B) IHC 2+/DISH-; C) IHC 1+ & 0/DISH+; and D) IHC 1+ & 0/DISH-. The presence of heterogeneity in relation to prognosis was analyzed in the IHC 0 & 1+/DISH- group.

Results:
The HER2 IHC 3+ group (27.5%), both with or without trastuzumab therapy, had significantly worse survival than HER2 IHC 1+ & 0 group (RFS: P=0.0039; CSS: P=0.0362) and HER2 DISH+ group (27.5%) had significantly worse survival than HER2 DISH- group (RFS: P=0.0056; CSS: P=0.0497). HER2 positive group defined by FDA criteria had significantly worse RFS than HER2 negative group (P=0.0211). HER2 IHC 1+ & 0/DISH+ group had significantly worse RFS than IHC 1+ & 0/DISH- group (P=0.0208). In the HER2 IHC 1+ & 0/DISH- group, patients with heterogeneity (33 cases) had significantly worse survival than those without heterogeneity (RFS: P=0.0176; CSS: P=0.0199).

Conclusions:
HER2 GPA technology might be useful for evaluating the discrepancy and heterogeneity of HER2 IHC and DISH results at single cell levels simultaneously and the presence of HER2 tumor cell heterogeneity might be a potent prognostic factor in HER2 negative breast cancer patients. Further clinical research must be conducted for clarification of the relationship between the presence of HER2 intratumoral heterogeneity and the effectiveness of HER2-targeted therapies.
Title: HER2/Neu genetic heterogeneity analysis in breast carcinoma

Yuan Sheng¹, Yanmei Wu², Kainan Wu³, Zhongzhong Chen⁴ and Yue Yu⁵.¹Changhai Hospital, Second Military Medical University, Shanghai, China;²Changhai Hospital, Second Military Medical University, Shanghai, China;³Changhai Hospital, Second Military Medical University, Shanghai, China;⁴Changhai Hospital, Second Military Medical University, Shanghai, China and ⁵Changhai Hospital, Second Military Medical University, Shanghai, China.

Body: Both immunohistochemistry (IHC) for detecting protein expression and fluorescence in situ hybridization (FISH) for gene amplification are accepted methods of determining clinical HER2 (or ERBB2) status. However, analysis of traditional clinical and pathological prognostic markers often misses the inherent heterogeneity of breast carcinoma. The reliability of IHC and FISH is questionable, and less than half of the patients with HER2-positive cancer will respond to trastuzumab therapy. The genetic heterogeneity (GH) of breast carcinoma is a major cause that makes its diagnosis and treatment far from being optimal. The impact of GH on patient outcome and the underlying mechanisms are lacking. To clarify the impact of FISH and IHC testing on HER2 GH, a total of eight studies with 11478 patients retrieved from PubMed and Embase were performed in this study. HER2 GH was noted in 27.8% of breast carcinomas, and the percentage ranged from 2.5% to 33.5%. HER2 GH existed in 84.0% FISH equivocal test and 30.8% IHC equivocal (IHC 2+) test. Further analysis showed the significant statistical differences between GH and different HER2 expression by FISH test ($\chi^2=864.23$, $P<0.001$), and between GH and different HER2 expression by IHC test ($\chi^2=206.52$, $P<0.001$), respectively. Forest plots displayed the discrepancy of GH frequency existed in the different ethnicities. Networks revealed that ERBB2 regulates different downstream proteins to coordinate numerous processes. Our results revealed that GH of HER2 differentially presented in a subset of HER2 amplified breast carcinomas, especially in cases with HER2 expression (FISH equivocal and IHC equivocal). There is a substantial difference in the frequency of GH among different ethnicities. HER2 GH is more likely to exist in FISH equivocal test than IHC equivocal test, and more convenient to document GH status by FISH test. Various HER2 genetic heterogeneity may activate diverse downstream signaling processes and play a different role in the pathogenesis of breast carcinoma.
Title: The non-coding transcriptome of hypoxic breast cancer: Novel insights of clinical relevant long non-coding RNA in hypoxia signalling

Hani Choudhry¹,³, Johannes Schodel², Ashwag Albukhari³, Syed Haider³, Francesca Buffa³, Peter J Ratcliffe⁴, David R Mole⁴, Ioannis Ragousis⁵ and Adrian L Harris³. ¹King Abdulaziz University, Jeddah, Saudi Arabia; ²Friedrich-Alexander-University, Erlangen-Nuremberg, Germany; ³University of Oxford, Oxford, United Kingdom; ⁴Henry Wellcome Building for Molecular Physiology, University of Oxford, Oxford, United Kingdom and ⁵McGill University and Genome Quebec Innovation Centre, Montreal, Canada.

Body: Hypoxia is associated with aggressive and poor prognosis of breast cancer. Generally, pan-genome analyses of hypoxia have focussed on protein-coding genes, however, the role of non-coding RNAs, in particular long non-coding RNAs (lncRNA) in hypoxia is not well characterised. We undertook an integrated genomic analysis of the hypoxic transcriptome in MCF7 breast cancer cells, employing total RNA-seq together with ChIP-seq for the hypoxia-inducible transcription factor (HIF) and for epigenetic marks of transcriptional activation (RNApol2 and histone H3K4me3).

Analyses revealed that all classes of RNA are significantly regulated by hypoxia including piwiRNA, miRNA, tRNA, and sn/snoRNA. Significant numbers of lncRNAs were upregulated in hypoxia and were associated with increased RNApol2 and H3K4me3 markers and with HIF binding, indicating direct transcriptional activation of lncRNAs by HIF. The most hypoxically upregulated IncRNA was NEAT1, which is a direct transcriptional target of HIF-2a but not HIF-1a. The role of NEAT1 in cancer has not been previously studied.

We demonstrated that hypoxic NEAT1 induction is common in breast cancer cell lines and xenografts models treated with bevacizumab. NEAT1 directly induces the formation of nuclear paraspeckle bodies in hypoxia. Moreover, it contributes to tumourigenicity by increasing cell proliferation, colony formation, and reducing apoptosis. In addition, we report that NEAT1 is required to retain hypoxia induced hyper edited Junctional Adhesion Molecule A (JAM-A) mRNA in the nucleus, thus preventing export into the cytoplasm for translation. Finally, in a large cohort of 2000 breast cancers, high levels of NEAT1 were associated with poor clinical outcomes and clinicopathological features.

Our results extend knowledge of the hypoxic transcriptional response into the spectrum of non-coding transcripts. These findings provide novel mechanisms of transcriptional regulation in hypoxia and open new avenues to find novel pathways and targets to develop therapies for breast cancer.

Title: Preliminary translational results from PROMIX, a phase II trial of preoperative chemotherapy with the addition of bevacizumab in large operable and locally advanced HER2-negative breast cancer

Niklas Loman1,5, Ida Johansson5, Judith Bjöhle3, Jan Frisell2, Tobias Lekberg3, Lisa Rydén4,5, Anna von Wachenfeldt3, Jonas Bergh3, Thomas Hatschek3 and Ingrid Hedenfalk5. 1Lund University Hospital, Lund/Malmö, Sweden; 2Karolinska University Hospital, Stockholm, Sweden; 3Karolinska University Hospital, Stockholm, Sweden; 4Lund University Hospital, Lund/Malmö, Sweden and 5Department of Clinical Sciences, Lund, Sweden.

Body: Background: Preoperative chemotherapy in breast cancer (bc) provides unique possibilities to evaluate effects of therapy by studying response and changes in the tumor during the course of treatment. A pathologic complete response (pCR) correlates positively with long term prognosis in high-proliferating bc. In triple negative bc (TNBC) the prognosis was still relatively serious in cases with pCR in one large meta-analysis (Cortazar Lancet 2014).

Methods: 150 cases were included in this multicenter study, and treated with six cycles of epirubicin and docetaxel, adding bevacizumab from cycle 3, before surgery. Core needle biopsies were collected at free hand or with ultrasound (US) guidance and snap frozen at base-line and after cycle 2, tissue was also collected at surgery. Subtyping was performed using immunohistochemistry (IHC) of ER, Ki67 and HER2 according to modified St Gallen criteria; and using bead array gene expression profiling (GEX) according to PAM50.

Results: Biopsies were successfully retrieved from 145/150 pts at baseline, 138 after cycle 2 and 139 at surgery. The mRNA yield was adequate for GEX from 123/145 (85%) at baseline, 82/138 (59%) at cycle 2 and 71/139 (51%) at surgery, the decrease being a result of tumor shrinkage during treatment.

Initial PAM50 subtypes were as follows: luminal A (LA) 20%, luminal B (LB) 45%, HER2 5 %, basal like (BL) 22% and normal like (NL) 8%. PAM50 at baseline differed compared to IHC subtypes. Among IHC defined LA-like cases 15/33 (45%) were classified as LB by PAM50. Similarly, among IHC LB-like 22/57 (39%) were classified as non-LB (6 basal, 8 LA, 3 HER2 and 5 NL), while among IHC TNBC 7/28 (25%) were classified as non-BL subtypes (1 LA, 3 HER2 and 3 NL).

Of the pts with a baseline GEX analysis, 17 (14%) achieved a pCR. The observed pCR rates among PAM50 subtypes were: LA 8%, LB 5%, HER2 17%, BL 53% and NL 20%. For non-pCR cases, 39/52 (75%) of the tumors changed PAM50 subtype between baseline and surgery. The majority changed to the NL subtype. 33% of the LB tumors changed to the LA subtype. Currently, after 2.2 years of follow-up, 16 pts are deceased due to bc. Among BL cases, 6/9 pts with a pCR at surgery remain alive; while 3/9 have died from bc. Exploratory analyses using functional gene modules (Desmedt Clin Cancer Res 2008) suggest that patients with BL tumors who have died have higher scores for PLAU/invasion and lower scores for STAT1/immune response compared with those who are still alive. Tumor size at baseline did not obviously correlate with outcome.

Conclusion: We show that biological material can be retrieved from a substantial fraction of cases treated within a multicenter study of preoperative chemotherapy. The success rate may be ameliorated by routine use of US guidance. The distribution of subtypes differs between modified IHC St Gallen criteria and PAM50, especially within the luminal subtypes. The pCR rate is highest among cases with a BL tumor at baseline. Shift of the gene signature between different subtypes during the course of treatment is frequent. In this set of relatively large tumors, the prognosis among BL bc appears to be adverse in spite of a pCR.

Title: Anastrozole and everolimus in hormone receptor-positive metastatic breast cancer: Safety profile, activity and associations of molecular alterations in the PI3K/AKT/mTOR pathway

Jennifer J Wheler¹, Filip Janku¹, Stacy L Moulder¹, Aung Naing¹, Sarina A Piha-Paul¹, Gerald S Falchook¹, Ralph G Zinner¹, Apostolia M Tsimberidou¹, Siqing Fu¹, David S Hong¹, Johnique T Atkins¹, Roman Yelensky², Vince Miller², Philip J Stephens², Vincente Valero¹, Funda Meric-Bernstam¹ and Razelle Kurzrock³. ¹UT MD Anderson Cancer Center, Houston, TX; ²Foundation Medicine, Cambridge, MA and ³UC San Diego, Moores Cancer Center, La Jolla, CA.

Body: Background
Combining aromatase inhibitors with PI3K/AKT/mTOR inhibitors in patients with hormone receptor (HR)-positive metastatic breast cancer has demonstrated clinical efficacy. There is limited data on associations between molecular signatures and activity.

Patients and Methods
We evaluated the combination of anastrozole and everolimus in 56 patients with HR-positive, metastatic breast cancer. The primary objective was to establish safety and maximum tolerated dose (MTD). Dose limiting toxicities (DLTs) were defined as serious grade 3 or 4 toxicities related to treatment that occurred during cycle 1. Dose level 1 was anastrozole 1 mg PO QD and everolimus 5 mg PO QD and dose level 2 was anastrozole 1 mg PO QD and everolimus 10 mg PO QD (a dose level -1 included everolimus 2.5 mg PO QD). Secondary endpoints included evaluation of antitumor activity and molecular associations with response. When tissue was available, Next Generation Sequencing (NGS) was performed using genomic libraries selected for all exons of 236 (or 182) cancer-related genes sequenced to average depth of >500× in a CLIA laboratory (Foundation Medicine, Cambridge, MA, USA). An analysis was then performed for all classes of genomic alterations.

Results
The median age was 59 (range, 37-82) and the median number of prior therapies in the metastatic setting was 3 (range, 0-13). The initial oral daily dose of anastrozole 1 mg oral and everolimus 10 mg PO daily was well tolerated. Five dose-limiting toxicities (DLTs) were seen at full doses, including grade 3 thrombocytopenia (1 patient), grade 3 neutropenia (1 patient), grade 3 increased liver enzymes (1 patient), grade 3 hyperglycemia (1 patient) and, grade 3 mucositis (1 patient). The most common grade 3 or 4 treatment-related toxicities were neutropenia (5%), increased liver enzymes (5%), and hyperbilirubinemia (3%). Of the 56 patients on study, 36 were tested for at least one molecular alteration in the PI3K/AKT/mTOR pathway. Twelve of these 36 patients had NGS analysis of their tumor tissue. Eighteen of 36 patients (50%) tested had at least one alteration in the pathway, including mutations in PIK3CA (n=16), PIK3R1 (n=1), and AKT1 (n=2); PTEN protein loss (n=1); and, AKT3 amplification (n=1). Sixteen of 56 evaluable patients (29%) achieved stable disease (SD) / partial response (PR) / complete response (CR) ≥ 6 months (n = 3 (5%) with PR/CR). Thirteen of the 16 patients who achieved SD/PR/CR ≥ 6 months were tested for a genetic alteration in PI3K/AKT/mTOR pathway and 7 of these patients (54%) had at least one alteration in the pathway, including mutations in PIK3CA (n=6), PIK3R1 (n=1), and AKT1 (n=1); PTEN loss (n=1); and AKT3 amplification (n=1).

Conclusions
Combination anastrozole 1 mg and everolimus 10 mg is well tolerated and is active in heavily-pretreated patients with HR-positive breast cancer. The presence of a molecular alteration in the PI3K/AKT/mTOR pathway did not predict for clinical activity of this combination.
**Title:** Gene expression associated with poor prognosis of young TNBC patients

Thomas Karn¹, Lajos Pusztai², Cornelia Liedtke³, Giampaolo Bianchini⁴, Balazs Győrfy⁵, Christos Hatzis², Achim Rody³, Volkmar Müller⁶, Marcus Schmidt⁷, Uwe Holtrich¹ and Sven Becker¹. ¹Goethe-University, Frankfurt, Germany; ²Yale Cancer Center, New Haven, CT; ³University Hospital Lübeck, Germany; ⁴Ospedale San Raffaele, Milan, Italy; ⁵Hungarian Academy of Sciences, Budapest, Hungary; ⁶University Hospital, Hamburt, Germany and ⁷Johannes Gutenberg University Mainz, Mainz, Germany.

**Body:**

**Background:**
Among TNBC patients those of very young age (<40 years) display a significantly worse prognosis (Liedtke et al. 2013 Breast Cancer Res Treat). We verified this result in 1161 TNBC samples with full Affymetrix gene expression data of which 845 patients had both detailed age and follow up information.

**Materials and Methods:**
We split the full sample set into a finding cohort of 394 TNBC and a validation cohort of 767 TNBC encompassing 309 and 536 samples, respectively, with both age and follow up data. We then used significance analysis of microarrays (SAM) in the finding cohort to look for genes whose expression is associated with young age (<40 years). Identified genes were analyzed for their correlations to known metagenes characteristic for different TNBC subtypes. Subsequently the whole analysis was repeated in the validation cohort.

**Results:**
We identified 98 and 222 probesets by SAM in the finding and validation cohort, respectively. Only a subset of identical probesets (19.4%) was re-identified in the validation. However, the gene lists were similarly enriched for correlations to specific metagenes and the respective TNBC subtypes. We found that young age among TNBC is positively correlated with increased proliferation and a basal-like subtype, but negatively correlated with the molecular apocrine phenotype and the claudin-low subtype. We also observed a negative correlation of young age with stromal enrichment and EMT but no difference in lymphocyte infiltration as judged by specific metagenes. However, despite that TNBC of patients <40 years have a poor prognosis (P=0.006) and are clearly enriched in basal-like subtype (70.7% vs 55.3%; P=0.001), still basal-like TNBC do not differ from non-basal-like TNBC in prognosis. Moreover, even within the group of basal-like TNBC the prognostic effect of age<40 was still observed (P=0.008). Interestingly, the changes in expression of single genes and metagenes were observed over a wide age range of 35-85 years. In contrast the difference in prognosis was markedly pronounced at the 40 year age limit. Thus, potential critical differences in gene expression associated with poor prognosis of TNBC <40 years seem to be concealed by many age-associated changes without prognostic value.
Title: A four gene signature predicts anthracycline benefit: Evidence from the BR9601 and MA5 breast cancer trials

Melanie Spears¹, Nicola S Lyttle¹, Fouad Yousif¹, Alison F Munro², Christopher Twelves³, Kathleen I Pritchard⁴,⁵, Mark N Levine⁶, Lois Shepherd⁷ and John MS Bartlett¹,²,⁵. ¹Ontario Institute for Cancer Research, Toronto, ON, Canada; ²Edinburgh Cancer Research Centre, Edinburgh, United Kingdom; ³University of Leeds and Cancer Research UK Centre, Leeds, United Kingdom; ⁴Sunnybrook Odette Cancer Centre, Toronto, ON, Canada; ⁵University of Toronto, Toronto, ON, Canada; ⁶McMaster University and Hamilton Health Sciences, Hamilton, ON, Canada and ⁷NCIC Clinical Trials Group, Queen’s University, Kingston, ON, Canada.

Body: Background: Chromosome instability (CIN) in solid tumours is associated with poor prognosis and results in numerical and structural chromosomal aberrations. Recent evidence from both the BR9601 and MA.5 trials has demonstrated CEP17 duplication as a predictive marker of anthracycline benefit. CIN25 and CIN70 gene expression profiles have previously been published and predict survival response. An analysis of the BR9601 and MA5 clinical trials was performed to test the role of CIN gene expression signatures as a marker of anthracycline sensitivity.

Methods: RNA was extracted from patients in both the BR9601 and MA5 studies and analysed through Nanostring technology. Log-rank analyses explored the prognostic values of the signatures on distant relapse-free survival (DRFS). Cox-regression models tested independent prognostic value on DRFS in the presence of treatment, age, tumour size, nodal status, ER status and grade, and treatment by marker interactions.

Results: Of the 761 samples available from the BR9601 and MA5 cohorts we successfully analysed 703 (92.4%). High CIN25 and CIN70 scores were associated with age (p<0.0001), grade (p<0.0001), PgR negativity (p<0.0001) and ER negativity (p<0.0001). In univariate analysis, high CIN25 score was associated with decreased DRFS (HR: 0.74, 95% CI 0.54-0.99, p=0.046). In a multivariate analysis with adjustment for size, nodal status, ER, pathological grade, HER2, CIN25, treatment and treatment by marker only pathological grade, nodal status and tumour size were significant predictors of outcome.

A more limited set of genes that reflected CIN was established by examining the expression profile of the genes and clustering them. The combined cohort was split into a 60% training and 40% validation set. The area under the curve (AUC) was calculated and the gene signature with the greatest AUC was selected and termed CIN4. Patients with low CIN4 score benefited from anthracycline treatment compared to those that had high CIN4 score (HR 2.72, 95% CI 1.48-5.02, p=0.001). No significant benefit with CMF treatment was observed in (HR: 1.02, 95% CI 0.58-1.82, p=0.92). After multivariate analysis the treatment by marker interaction for CIN4 had a hazard ratio of 2.10 (95% CI 2.18-30.38, p= 0.001).

Conclusion: High CIN70 and CIN25 scores were associated with an aggressive phenotype and showed a potential increased sensitivity to anthracycline therapy compared to those with low CIN scores. CIN4 was an independent predictor of anthracycline benefit for DRFS. However, further work in larger patient cohorts such as NEAT is warranted.
Identification of specific gene signatures and alternative splice variants using exon array in Inflammatory breast Cancer

Florence Lerebours¹, Sophie Vacher², Marie Le Cann², Sophie Rondeau², David Gentien², Steven Van Laere³, François Bertucci⁴, Pierre de la Grange⁵ and Ivan Bieche². ¹Institut Curie, Hospital Rene Huguenin, Saint-Cloud, France; ²Institut Curie, Paris, France; ³General Hospital Sint Augustinus, Wilrijk, Belgium; ⁴Institut Paoli-Calmettes, Marseille, France and ⁵Genosplice, ICM, Hospital Pitie Salpetriere, Paris, France.

Body: Inflammatory Breast Cancer (IBC) is a rare form of breast cancer with a particular phenotype and aggressiveness. Although significant progress has been made in the management of IBC, the prognosis remains poor. Intensive research on IBC has allowed identification of several candidate genes and pathways, but molecular findings unique to IBC have yet to be identified to improve treatment and survival. Transcriptomic studies have revealed a marked heterogeneity of IBC with limited gene overlap between studies, preventing the identification of a sensitive and specific signature in IBC.

In order to detect both gene expression levels and alternate RNA splice isoforms, we chose to perform splice-sensitive array profiling using Affymetrix Exon Array in a well-defined series of 33 IBC (core biopsies from previously untreated T4d carcinomas) compared with 28 stage I to non-inflammatory stage III breast cancers.

Gene expression analysis allowed the identification of classical molecular subtypes in both IBC and non-IBC, with overrepresentation of basal-like (17/33 vs 9/28) but no luminal A in IBC (vs 11/28). Based on Fold-Change (FC) ≥ 1.5 and p-value < 0.05, 495 genes were significantly dysregulated between IBC and non-IBC, including in particular up-regulated hemoglobin genes and down-regulated ER-related genes in IBC compared to non-IBC. Most activated pathways were hematopoietic cell lineage, cytokine-cytokine receptor interaction, chemokine signalling pathway and complement and coagulation cascade. We defined a 21-gene signature discriminating IBC from non-IBC with 8% error rate. To get rid of genes associated with molecular subtypes like ER-related genes, an analysis restricted to basal-like BC (17 IBC compared to 9 non-IBC) was performed allowing the definition of a 29-gene signature discriminating the whole groups of IBC from non-IBC with 3.3% error rate. Validation of this signature in the gene expression datasets from the World IBC Consortium will be presented.

Specific exon expression analysis revealed that when based on FC splicing-index and p-value, 266 exons representing 177 distinct genes were differentially regulated between IBC and non-IBC. After manually curation of results, 13 splice events representing 12 distinct genes were retained as good candidates for alternative splicing in IBC (EVL, RPL10, MYH10, HSPA8, DOCK7, DIDO1, RPL4, TRAK1, RGS1, LMO4, SMARCA4, ZNF337).

To confirm gene-signatures specific to IBC, altered pathways and major splice variants, we are performing a validation study using quantitative RT-PCR in the screening set (n=33) and in an independent series of 140 IBC compared to 200 non-stage-matched non-IBC. Finally the most dysregulated genes will also be studied at the protein level using immunohistochemistry.

Title: Feasibility and sensitivity of fine-needle aspiration biopsies for the detection of somatic mutations using next-generation sequencing in breast cancer

Han-Byoel Lee¹, Jisun Kim², Kyung-Min Lee³, Je-Gun Joung⁴, Hae-ock Lee⁴, Min Kyoon Kim¹, Eunshin Lee¹, Jongjin Kim¹, Tae-Kyung Yoo¹, Yun-Gyoung Kim¹, Young Joon Kang¹, Han Suk Ryu⁵, In-Ae Park⁶, Hyeong-Gon Moon¹, Dong-Young Noh¹, Woong-Yang Park⁶ and Wonshik Han¹. ¹Seoul National University College of Medicine, Seoul, Korea; ²Asan Medical Center, Seoul, Korea; ³Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea; ⁴Samsung Genome Institute, Samsung Medical Center, Seoul, Korea; ⁵Seoul National University College of Medicine, Seoul, Korea and ⁶Samsung Genome Institute, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea.

Body: Background/Purpose: Next-generation sequencing (NGS) is being incorporated rapidly into clinical practice. Fine-needle aspiration biopsy (FNAB) specimens have been used feasibly in molecular analysis including direct sequencing and microarrays. They are readily available and enriched in malignant cells, thus providing opportunities for genomic analysis for more clinical samples. In this study, we assessed the feasibility and sensitivity of FNAB for the detection of somatic mutations by NGS compared to bulk tissue.

Methods: Bulk tissue and FNAB was sampled via skin superficial to the palpable tumor from surgically resected breast cancer specimen. DNA was extracted from the bulk tissues and FNAB samples obtained from twelve patients. Somatic mutations detected from whole exome sequencing (WES) by next-generation sequencing (NGS) (HiSeq 2500, Illumina) were analyzed for corresponding pairs of bulk tissue and FNAB. Verification of somatic mutations detected exclusively from FNAB and known to be clinically relevant to breast cancer was carried out by Sanger sequencing. Invasive tumor percentages of bulk tissues were evaluated using hematoxylin and eosin (H&E)-stained sections.

Results: Average depth of coverage were 158.8x and 158.3x for bulk tissue and FNAB, respectively. Number of detected somatic mutations ranged from 2 to 153 (median 18.5) and 19 to 210 (median 39.5) for bulk tissue and FNAB, respectively. Ten specimens had more mutations detected exclusively from FNAB than from bulk tissue. Allele fractions plotting of corresponding pairs of bulk tissue and FNAB showed good, intermediate, and poor correlation in five, two, and five specimens, respectively. H&E-stained sections of bulk tissue from the five specimens with good correlation contained an invasive tumor percentage of 45 to 98%, whereas those from five specimens with poor correlation contained 0 to 25%. Three of the poorly correlated bulk tissues were judged to have 0% of invasive tumor. Among mutations detected exclusively from FNAB, eighteen different genes of interest in 22 foci were evaluated for both FNAB and corresponding bulk tissue by Sanger sequencing. In the results, three mutations (PIK3CA, TP53 x2) were verified in FNAB samples but not in the bulk tissue.

Conclusion: WES was successfully carried out in all pairs of bulk tissue and FNAB from twelve breast cancer patients. In samples with high tumor content somatic mutation profiles showed high correlation between the two samples whereas samples with low tumor content failed to show correlation. The failure was mostly due to the scarcity of tumor portions in the bulk tissues, indicating that FNAB more reliably retained malignant tumor portion. This study suggests that FNAB is an easy and feasible method, and furthermore, provides a more reliable specimen for NGS analysis where somatic mutations could be identified for potential prognostic or therapeutic benefits.
Title: The molecular landscape of breast ductal carcinoma in situ (DCIS)

C Marcelo Aldaz, Martin C Abba, Ting Gong, Yue Lu, Jaeho Lee, Jianjun Shen, Marcos R Estecio, Yoko Takata, and Aysegul A Sahin. 1University of Texas MD Anderson Cancer Center â–“ Science Park, Smithville, TX; 2CINIBA, Facultad de Medicina, Univ. Nac. de La Plata, La Plata, Pcia. de Buenos Aires, Argentina and 3University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Ductal Carcinoma in situ (DCIS) is by definition a local cancerous condition with no regional or lymph node involvement and is a precursor lesion to invasive ductal carcinomas (IDC). However, we have no understanding on why only some DCIS lesions evolve to IDC while others appear not to do so during the life span of the patient. The massive use of screening mammography has led to a dramatic increase in DCIS detection in the last three decades. This significant increase in DCIS detection has led to an 'overdiagnosis and overtreatment problem'. It has been argued that in 2008 breast cancer was overdiagnosed in > 70,000 women in the US and that the increase in DCIS and localized breast cancer detection was not followed by a corresponding decrease in the incidence of late stage cancer. As a second issue, most DCIS patients are recommended to receive post-surgery adjuvant therapies that may be unnecessary for most patients and this in itself constitutes an additional overtreatment conundrum.

Importantly, no biomarkers exist for facilitating the distinction of DCIS lesions with higher chance of progression vs. lesions unlikely of progressing. A detailed analysis of the mutational landscape of ‘pure’ DCIS lesions, coupled with a deeper understanding of the transcriptome and epigenome of these lesions, will be instrumental to uncover the molecular mechanisms and pathways that govern the natural progression of pre-malignant breast lesions. To this end we are profiling the genome (Exome-seq) transcriptome (RNA-seq) and methylome (RRBS) of normal and DCIS matched samples as well as normal organoid specimens. Our DCIS Exome-seq data showed an average mutation rate of 9.1 mutations/Mb, with a range of 4.2 to 19.5, indicating that some DCIS have significantly higher mutation rates than others.

All ‘pure’ HGDCIS samples showed somatic mutations affecting multiple genes and 75% of cases displayed mutations affecting targets described as ‘cancer gene drivers’ and candidate drivers. Among these we detected mutations affecting TP53 (22% of cases), PIK3CA (22%), GATA3 (9%), MLL3 (9%) and mutations affecting CDH1, MAP2K4, USH2A, NF1, ATM and various epigenetic regulators were also observed. Interestingly, no mutations were detected so far in some genes reported as commonly mutated in invasive breast cancer. Exome-seq results were validated by RNA-seq data.

Integrated pathway-based modeling analysis (PARADIGM) of RNA-seq data allowed us to identified DCIS subgroups that differ in the activity of a plethora of signaling pathways such as FOXM1, AP1, miR-34a, E2/ER, and immune signatures. Comprehensive analysis of RNA-seq and RRBS data allowed us to identify specific genes and pathways commonly silenced by CpG islands promoter's methylation.

Our final goal is: to frame at what stage in the DCIS progression specific mutations take place, define which molecular abnormalities are cause (drivers) or consequence of progression, and ultimately better stratify DCIS subgroups based on the biomarker profiles obtained.

Supported in part by CPRIT Core Facility Support Grant RP120348.
Title: Functional mapping of the oncogenic kinome activity of triple-negative breast cancer cells

Bo Pan¹,², Miki Mori¹,³, Pei Rong Evelyn Lee¹, Marij Hartog¹, Qiang Sun², Laura van 't Veer¹ and Jean-Philippe Coppe¹.
¹Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA; ²Peking Union Medical College Hospital, Beijing, China and ³Showa University, 5-8 Hatanodai 1-chome, Shinagawa-ku, Tokyo, Japan.

Body: Background: Triple-negative breast cancer (TNBC) accounts for approximately 10 to 15% of all breast cancer cases. The management of TNBC cases will significantly improve once molecular mechanisms specific to TNBC cells will be identified and treated accordingly. Evidence suggests that TNBC cells display deregulated kinase-dependent signaling cascades that differ from non-triple-negative breast cancer cells. We hypothesized that uniquely divergent phospho-circuits could be distinguished between TNBC and non-TNBC cell lines. By revealing such unique, dysfunctional phospho-signaling network, our long-term objective is to identify kinases that underpin triple-negative breast cancer development, and can be inhibited using targeted therapy.

Methods: The kinome activity of TNBC and non-TNBC cell lines was identified (HCC70, MDA-MB-231, MDA-MB-436 compared to AU565, MCF-7, T47D). The functional phospho-signature of each breast cancer cell was analyzed using a high throughput experimental platform that monitors the level of activity of myriad kinases at once. This technique uses 242 phospho-sensing probes and 78 controls in an aqueous-based assay to simultaneously and directly measure the phospho-catalytic activity of phosphorylating enzymes in cell lysates. We mapped the most significantly deranged phospho-signaling cascades and the related kinases.

Results: Using 6 cell lines tested under various conditions, we generated 72 phospho-signatures, out of a total of 23,040 data points. After validating the repeatability and robustness of the assay, the kinase activity signature of each breast cancer cell line was analyzed and compared to each other using unsupervised hierarchical clustering. The phospho-sensing assay revealed the heterogeneity of kinase activity networks among breast cancer cells. These data also established that phospho-signaling cascades related to AKT, ERK, and SRC kinases were differentially altered in TNBC and non-TNBC cell lines.

Conclusions: We successfully identified unique phospho-circuits of TNBC and non-TNBC cell lines. Our goal is now to test whether specific kinase inhibitors can efficiently kill or prevent the growth of TNBC cell lines in culture and animal models. We will expand our approach into a high-content, functional kinome-screening platform to characterize the phospho-fingerprint of breast cancer cells and tissues, and explore the druggable, kinase-dependent mechanisms critical to triple-negative breast tumors.
Title: Explore the differences and relationships between normal and ADH, DCIS and IDC tissues in breast based on Raman spectroscopy

Bing Han¹, Haipeng Zhang¹, Chao Zheng¹, Ye Du¹, Lijia Liang², Weiqing Xu² and Zhimin Fan¹. ¹First Hospital of Jilin University, Changchun, Jilin, China and ²State Key Laboratory for Supramolecular Structure and Materials, Jilin University, Changchun, Jilin, China.

Background: Atypical ductal hyperplasia (ADH) is a premalignant breast lesion associated with an increased risk of breast cancer which shares some but not all the features of ductal carcinoma in situ (DCIS). The mechanism that ADH changes to DCIS and even invasive ductal carcinoma (IDC) is still not clear now. There is a pressing need to develop screening techniques that are accurate, minimally invasive and, more sensitive to identify early neoplastic changes and hence improve early breast cancer diagnosis. Our aim was to explore the differences and relationships between normal, ADH, DCIS and IDC lesions of the breast based on biochemical characteristics determined by Raman spectroscopy.

Methods: Frozen sections were collected from 39 patients (all ladies) who underwent surgical resection or mammotome biopsy at the Department of Breast Surgery, the First Hospital of Jilin University. After operation the samples were immediately frozen at -20-25 ° and two contiguous sections (6 µm thickness) were cut from a sample by freezing microtome. One was stained with haematoxylin and eosin for routine histopathological analysis; the same position of the other section was detected by Microscopic confocal Raman spectrometer (HORIBA JY Lab800, 633nm) with its mirror image (the H&E section). After Raman measurement, the sections were routinely processed, stained with H&E and histologically examined. Support vector machine (SVM) was used to differentiate different breast lesions.

Results: A total of 475 Raman spectra were obtained from 9 normal breast tissues, 7 ADH, 8 DCIS, and 15 IDC breast tissues. Pronounced mean Raman spectra differences were observed between normal tissues, ADH, DCIS and IDC tissues. The significant features of normal tissues are 1301, 1438, 1652, and 1743 cm⁻¹, these peak positions are attributed to lipids, and the spectra profiles of normal tissues have no strong protein peaks. Most noticeable was the increased protein and reduced lipid levels of ADH tissues compared to normal tissues. The peak relative intensity of 1158 cm⁻¹ which is attributed to the vibrational modes of C-C stretch of proteins has significantly increased from normal tissues to DCIS and IDC in breast. The major spectra differences in ADH, DCIS and IDC spectra were evidenced by a red shift with a broad peak of CH2, the intensity of the stretching vibration peak of carotenoids, a relatively strong band of amide-I, and the nuclear acid peak. ADH tissues had the largest constituent variations between subjects. During the disease progression, IDC tissues have smaller inter-subject constituent variations than DCIS and ADH tissues. The accuracies of SVM are 93% and 95% in discriminating normal and IDC, while only 50% and 51% in discriminating ADH and DCIS.

Conclusion: Malignant transformations in tissue are associated with complex biochemical changes and may provide an effective way to evaluate the malignancy by Raman spectroscopy as it reveals differences between normal tissues, ADH, DCIS and IDC tissues in the breast. Further study to explain the biochemical relationships between these differences will shed more light into a better understanding of the mechanism by which ADH and DCIS convert to IDC.
Title: Genetic profiling of breast cancer confirms a pivotal role of EGFR pathway in the development of acquired resistance to tamoxifen

Rabab M Gaafar¹, Abeer A Bahnasy¹, Osman M Mansour¹, Nasr M Allahloubi¹, Ibrahim A Malash¹ and Sabry M Shaarawy¹.
¹National Cancer Institute, Cairo University, Cairo, Egypt; ²National Cancer Institute, Cairo University, Cairo, Egypt; ³National Cancer Institute, Cairo University, Cairo, Egypt; ⁴National Cancer Institute, Cairo University, Cairo, Egypt; ⁵National Cancer Institute, Cairo University, Cairo, Egypt and ⁶National Cancer Institute, Cairo University, Cairo, Egypt.

Body: Background: Acquisition of resistance to tamoxifen remains a major drawback in the treatment of oestrogen receptor (ER)-positive breast cancers. Aberrant expressions of some genes in the EGFR pathway were associated to the acquisition of resistance in some studies.

Patients and methods: This prospective study was carried out on 157 female patients with hormone receptor positive, locally recurrent inoperable and/or metastatic breast cancer who presented to the National Cancer Institute, Cairo University during the period from October 2010 to October 2012. All patients received tamoxifen. Patients were divided into tamoxifen responsive and refractory groups according to their response to therapy.

In an attempt to understand the contribution of EGFR pathway to the development of resistance to Tamoxifen, we assessed the genetic profile of the EGFR pathway genes in the 2 groups. RNA was extracted from tumor and normal tissue samples obtained from all patients and the expression level of 92 genes was evaluated using the SABioscience array (Qiagen) with four house-keeping genes.

Results: Age ranged between 29 and 79 years but age ≤ 50 or > 50 did not correlate to resistance. Evaluation of Hormone receptor status showed that 58.59% were positive for both ER and PR, 32.48% were ER positive, PR negative and 8.91% ER negative PR positive. Neither hormone receptor status nor nuclear grade was correlated to drug resistance. There was a strong correlation between response to tamoxifen and disease site as patients with bone only disease demonstrated noticeable good and maintained response compared to those who had visceral involvement (p- 0.005). The expression levels of all genes were assessed in both studied groups: the responders (the control) and the refractory (tested) groups. Fifty six genes were differentially over-expressed in the refractory group compared to the responding group, among which only JAK1, COL1A1, GAB1, FN1 and MKNK1 showed a significant difference between responders and refractory groups. Thirty four genes were differentially expressed (reduced expression) in the refractory compared to the responders. Moreover, CYP2D6 *3, *4 were significantly prevalent in the refractory group (86.6%), whereas variants *10/*10 and *10/*3 were more common in the in the responding group (85.5%) (p = 0.027)

Conclusion: A panel of 5 genes (M JAK1, COL1A1, GAB1, FN1 and MKNK1) in EGFR pathway together with CYP2D6 polymorphisms could be used to predict patient’s response to tamoxifen though this has to be verified in an extended study including larger sample.
Title: Signatures of endocrine resistance in the tamoxifen and exemestane adjuvant multinational trial (TEAM)-UK cohort

Jane Bayani¹, Mary Anne Quintayo¹, Cindy Q Yao¹, Syed Haider¹, Cassandra Brookes², Paul C Boutros¹,³, John MS Bartlett¹ and Daniel W Rea². ¹Ontario Institute for Cancer Research, Toronto, ON, Canada; ²Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, United Kingdom and ³University of Toronto, Toronto, ON, Canada.

Body: Introduction: There are a number of commercially-available tests to stratify risk for women diagnosed with early breast cancer. While such “Generation I” tests are increasingly being used, a consensus is growing that these tests are moderately accurate in assessing risk. Moreover, Generation I tests fail to direct more personalized treatment. There exists, therefore, a clear need for more informative "Generation II" tests that have theranostic targets. To this end, we have performed an mRNA abundance-based analysis using the UK cohort of the TEAM trial to identify signatures of endocrine resistance, from which pathways for putative therapeutic intervention may be identified.

Methods: RNA extracted from 790 patients in the UK-TEAM cohort were profiled using a 165-gene NanoString codeset. The gene list was compiled from targets that comprise many of the existing risk assessment tests, in addition to genes known to be of importance for breast cancer pathogenesis. Signal intensities were normalized using the R statistical environment; 336 different combinations of preprocessing methods were assessed and the most optimal method selected using unbiased criteria.

Results: Univariate survival analysis revealed a number of significantly prognostic candidates. Using inter-gene correlation and consensus clustering, we identified five gene clusters. Not surprisingly, these clusters included a strong proliferation, hormone signalling and cell migration component. Derivation of risk scores using Cox proportional hazards model, with the inclusion of age and nodal status, generated a signature identifying patients with differences in distant relapse-free survival (DRFS). Moreover, the composition of the gene-list made it possible to characterize the patients into their intrinsic subtypes and to determine their relative risk for recurrence relative to assessment tools available today. The added value of subtyping and the gene clusters identified in this discovery cohort will be discussed.

Conclusions: The impact of test-guided therapy using multi-parametric tests is increasingly being felt in the clinic, and is reshaping modern health-care economics. A successful Generation II multi-parametric test will better discriminate those that are truly at high risk for recurrence following endocrine therapy and offer potential therapeutic options for intervention for those who would not benefit from current modalities.

Title: Transcriptomic profiling of patient sequential tumours provides cutting edge view of global metastatic expression changes following endocrine therapy

Jean McBryan¹, Ailis Fagan¹, Damian McCartan¹, Jarlath C Bolger¹, Fiona T Bane¹, Christopher Byrne¹, Marie McIlroy¹, Arnold D Hill¹ and Leonie S Young¹. ¹Royal College of Surgeons in Ireland, Dublin, Ireland.

Body: Disease recurrence is a common problem in breast cancer and yet the mechanisms enabling tumour cells to evade therapy and colonise distant organs remain unclear. Here, for the first time, RNAsequencing has been performed on matched primary, nodal and liver metastatic tumours from three tamoxifen-treated patients following metastatic disease progression. Despite all primary tumours being of a luminal subtype and all cancers metastasising to the liver, the extent of patient heterogeneity at the gene level was striking. Less than 3% of the genes differentially expressed between sequential tumours were common to all patients. Larger divergence was observed between primary and liver tumours than between primary and nodal tumours, reflecting both the latency time to disease progression and the genetic impact of endocrine therapy. Furthermore, a xenograft model demonstrated the ability of tamoxifen to drive disease progression and establish distant metastatic disease in the endocrine resistant setting. Common functional pathways altered during metastatic, endocrine-resistant progression included ECM receptor interactions and focal adhesions. This novel global analysis highlights the influence of primary tumour biology in determining the transcriptomic profile of metastatic tumours, as well as the need for adaptations in cell-cell communications in order for tumour cells to successfully colonise distant host organs.
Title: New treatment options for metastatic breast cancer revealed by reverse-phase protein microarray and genomic profiling

Casey B Williams', Pradip De', Nandini Dey', Kirstin A Williams', Jessica Klein', Michelle King', Misty Small', Brigitte Cyr', Scooter Willis', Yuliang Sun', Jennifer Carlson', Brandon M Young', Amy Krie' and Brian Leyland-Jones'. 'Avera Cancer Institute, Sioux Falls, SD.

Body: Background: The optimal treatment strategy for patients with metastatic breast cancer (MBC) is currently unknown. Resistance to standard therapies like anthracyclines and taxanes limit the number of treatment options in many patients to a small number of non-cross-resistant regimens. We hypothesized that genomic and proteomic profiling of clinical MBC samples would identify genomic alterations that are linked to targeted therapies, and that this could facilitate a personalized approach to therapy for our patients.

Methods: We retrospectively analyzed 31 consecutive metastatic breast cancer patients that had genomic and/or proteomic studies sent over a 4 month period from February to May 2014. All patients were seen in our Genomic Oncology Clinic and subsequently underwent a rebiopsy of a metastatic site. Formalin-fixed, paraffin-embedded (FFPE) tissue was sent to either Foundation Medicine for genomic profiling, Theranostics for reverse-phase protein microarray, or both. Standard immunohistochemistry for ER, PR, and HER2 was also performed on all patients.

Results: Genomic or proteomic alterations were identified in all 31 patients. All patients harbored at least one actionable target and a treatment recommendation for a currently available FDA approved drug or drug combination was able to be suggested in all but one patient. The most commonly observed genomic alterations were within PIK3CA (26%), TP53 (23%), CCND1 (19%), and MYC (16%). Over 30 distinct genomic alterations were identified. Proteomic results were available from 16 patients. Activation of the AKT/mTOR pathway was evident in a majority of patients. A change in HER2 status was also found in 26% of patients. 16% of cases underwent a negative to positive conversion in HER2 status while 10% of cases underwent a positive to negative conversion. It is notable that all 5 patients that underwent a negative to positive conversion in HER2 status had biopsies taken from metastatic disease in the liver.

Conclusions: All patients in this retrospective study harbored genomic or proteomic alterations that are associated with targeted therapies. Treatment recommendations were suggested in all but one patient and a majority of patients are receiving the suggested therapy. Our data demonstrate that routine genomic and proteomic analysis in a clinical setting makes a significant positive impact for patients.
Title: Exploring type II microcalcifications in benign, premalignant and malignant breast lesions by shell-isolated nanoparticle-enhanced Raman spectroscopy (SHINERS)

Haipeng Zhang¹, Bing Han², Chao Zheng², Ye Du², Lijia Liang³, Weiqing Xu³ and Zhimin Fan². ¹The First Hospital of Jilin University, Changchun, Jilin, China; ²First Hospital of Jilin University, Changchun, Jilin, China and ³State Key Laboratory of Supramolecular Structure and Materials, Jilin University, Changchun, Jilin, China.

Body: Background: Type II microcalcifications, most often seen in proliferative lesions, including both benign and malignant pathologies. But whether the emergence of type II microcalcifications associated with cell canceration is still not clear now. Raman spectroscopy is a powerful, non-invasive analytical tool which can provide detailed and meaningful information about biochemical composition of tissues at molecular level. Our aim was to find the differences and relationships of type II microcalcifications between fibroadenoma, ADH tissues, and DCIS, IDC in breast based on their various biochemical characteristics by Raman spectroscopy.

Methods: The frozen sections were collected from 15 patients (all female; ages 25-57) who underwent surgical resection or mammotome biopsy at the Department of Breast Surgery, the First Hospital of Jilin University. After operation the samples were immediately frozen at -20°C to -25°C and two contiguous sections (6 µm thickness) were cut from a sample by freezing microtome. One was stained with haematoxylin and eosin for routine histopathological analysis and found the microcalcification locations by three expert breast pathologists; the same position of the other section was detected by Microscopic confocal Raman spectrometer (HORIBA JY Lab800, 633nm) with its mirror image (the H&E section). After the spectra we needed had been obtained, the Au@SiO2 shell-isolated nanoparticles (SHINs) were added to the surface of frozen sections immediately and then the spectra with SHINs were collected.

Results: A total of 122 Raman spectra and 119 SHINERS spectra were obtained from the microcalcifications in 3 fibroadenoma tissues, 3 ADH, and 5 DCIS, 4 IDC breast tissues. The Raman signals were significantly enhanced by SHINs. Except the major peak at 958-960 cm⁻¹ which attributed to the vibrational modes of calcium hydroxyapatite, the results show no calcium oxalate dihydrate peaks but several other chemical species. The peaks of these species appear at 1002, 1072, 1126, 1446, 1556, and 1657 cm⁻¹, these are attributed to amino acid residue (phenylalanine), nucleic acids, lipids, carotenoids, and Amide I, respectively. The fibroadenoma and ADH microcalcifications mean spectral have the same peak at 1072cm⁻¹, which belongs to the O-P-O stretch of nucleic acids, but in DCIS and IDC tissues the peak changes to 1078cm⁻¹. The ADH have more obvious peak at 1657 cm⁻¹ which assigned to different vibrational modes of the backbone and Amide I, but in DCIS and IDC tissues, the Amide I bands were disappeared. In the DCIS microcalcifications mean spectral, the peaks attributed to amino acid residue (phenylalanine) at 1003, 1031 cm⁻¹ and lipids (CH2 and CH3 bending) at 1301, 1441 cm⁻¹ show more stronger. Meanwhile, compare with DCIS, the IDC spectral shows more stronger nucleic acids peaks and weaker lipids peaks.

Conclusion: We have demonstrated the potential of SHINERS to differentiate Type II microcalcifications found in fibroadenoma, ADH, and DCIS, IDC breast tissues. The results presented in this paper provide the biochemical characteristics of the Type II microcalcifications among these tissues, and may represent a key factor responsible for mechanisms of carcinogenesis.
Title: Gene expression in synchronous primary, axillary nodal and disseminated breast cancer cells

Reuben J Broom¹, Cherie Blenkiron³, Richard Harman², Erica Whineray Kelly², Stephen Allpress², Katherine Gale², Sam Rice², Peter Shin², Anna Brown², Annette Lasham³ and Cristin Print³. ¹Auckland City Hospital, Auckland, New Zealand; ²North Shore Hospital, Auckland, New Zealand and ³University of Auckland, Auckland, New Zealand.

Body: Disseminated Tumour Cells (DTC) have been found in the bone marrow (BM) of up to 70% of patients with breast cancer metastatic to axillary lymph nodes. They are a biologically and therapeutically interesting tumour cell population. Although there is uncertainty about their relationship to cancer prognosis, DTC provide a valuable window into the processes by which primary tumour (PT) cells disseminate. DTC can be enriched from BM by immunoaffinity using antibodies directed against epithelial cell markers such as EpCAM. To better understand the changing gene expression patterns that may accompany breast cancer metastasis, we have compared the whole genome RNA expression profiles of matched PT, axillary lymph node metastases (LNM), and EpCAM-enriched cells from the BM of seven patients. Compared to PT, axillary LNM had consistently altered expression of RNAs encoding matrix metalloproteinases (MMP), growth factors, transcription factors, as well as downstream targets of Catenin-a, Tumour Necrosis Factor (TNF)-a and miR-22. Once the gene expression patterns of potentially contaminating BM cells were subtracted, compared to PT and LNM EpCAM-enriched MB cells had consistently elevated expression of RNAs encoding metabolic enzymes, ribosomal proteins, and DNA-binding factors such as YB-1. The gene expression changes we identify are candidate mediators of breast cancer metastases and represent attractive targets for further study on a cell by cell basis.
Title: Development of a fluorescent reporter system to delineate self-renewing cells in triple negative breast cancer

Praveena S Thiagarajan¹, Masahiro Hitomi¹, James S Hale¹, Alvaro G Alvarado¹, Baltin Otvos¹, Kevin Stoltz¹, Maksim Sinyuk¹, Awad Jarrar¹, Qiao Zheng¹, Dustin Thomas¹, Thomas Egelhoff¹,²,³, Jeremy N Rich¹,²,⁴, Justin D Latia¹,²,³ and Ofer Reizes¹,²,³.
¹Cleveland Clinic Lerner Research Institute, Cleveland, OH; ²Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH; ³Case Comprehensive Cancer Center, Cleveland, OH and ⁴Cleveland Clinic Lerner Research Institute, Cleveland, OH.

Body: Background: Advanced cancers including triple-negative breast cancer (TNBC), the most aggressive breast cancer subtype, contain a self-renewing, tumorigenic cancer stem cell (CSC) population. CSCs contribute to tumor progression and therapeutic resistance. Despite an effective early response to chemotherapy, TNBC relapses with a highly heterogeneous and refractory metastatic disease enriched in CSCs. Apart from being chemo- and radio-resistant, CSCs display a high degree of multipotency, heterogeneity and plasticity. Due to the complex nature of CSCs, elucidating the characteristics of CSCs in TNBC progression continues to be a challenge. Thus, developing anti-CSC therapies to be integrated into clinical paradigms represents an immediate priority.

Rationale: A major obstacle to the identification of CSC regulatory mechanisms is the lack of experimental systems that enable the reliable enrichment of CSCs from non-CSCs for comparative analysis. While CSCs have been isolated from TNBC using CD44+/CD24- and/or ALDH+ phenotype, this enrichment paradigm requires refinement as it is not universally applicable and lacks the ability to study CSCs in real time. The limitations of these systems have excluded their application in studying the molecular heterogeneity among breast cancer tumors. CSCs are molecularly characterized based on the expression of cell surface receptors and the embryonic stem cell transcription factors NANOG, OCT4 and SOX2. NANOG, the master regulator of stem cell self-renewal, has emerged as a pro-carcinogenic factor in cancer cell lines with CSC behavior. Our previous studies have shown that silencing NANOG in cancer cells leads to reduced proliferation and self-renewal based on in vitro and in vivo experiments.

Hypothesis: We hypothesized that a Nanog promoter could be used to effectively enrich for TNBC CSCs.

Results: We generated two TNBC cell lines (MDA-MB-231 and HCC70) harboring NanogGFP reporter gene by lentiviral transductions. Increased NANOG mRNA and protein expression was observed in flow cytometry-sorted GFP+ cells compared with GFP- cells. GFP+ cells were enriched for the CSC markers CD49f and CD44+/CD24-. GFP+ cells also demonstrated an increased protein expression of the stem cell transcription factors NANOG, SOX2 and OCT4. Limiting dilution analyses revealed increased self-renewal and significantly higher stem cell frequencies in GFP+ cells. GFP+ cells demonstrated a mesenchymal phenotype with increased invasive capacity. Subcutaneous injections of GFP+ cells showed significantly higher in vivo tumor initiation and progression than GFP- cells. Flow cytometry-sorted GFP+ and GFP- cells enriched for CSCs and non-CSCs, respectively. Using this system, we performed a high-throughput flow cytometry screen and identified an additional novel CSC marker for TNBC.

Conclusion: We have developed a novel TNBC CSC reporter system using a GFP reporter driven by the Nanog promoter and identified a novel CSC marker. We have defined and validated this robust system wherein we have characterized and monitored the role of CSCs and non-CSCs in TNBC tumor initiation and progression. Using this approach, identifying CSC targets in TNBC could unravel the potential for development of innovative therapeutic strategies.
Title: Breast cancer stem-like cell activity correlates with tumour progression to metastasis but not with clinical or tumour characteristics

Sacha J Howell¹, Denis Alferez², Katherine Spence², Rachel Eyre², Fran Shaw¹, Bruno Simoes², Angelica Santiago-Gomez², Maria Bramley³, Mohamed Absar³, Zahida Saad⁴, Sumohan Chatterjee⁴, Cliona Kirwan¹, Ashu Gandhi⁵, Anne C Armstrong⁶, Andrew M Wardley⁶, Gillian Farnie¹ and Robert B Clarke¹. ¹University of Manchester, Institute of Cancer Studies; ²CRUK Manchester Institute; ³Penine Acute Hospitals NHS Trust; ⁴Salford Royal NHS Foundation Trust; ⁵University Hospitals of South Manchester NHS Foundation Trust and ⁶Christie NHS Foundation Trust, Manchester, United Kingdom.

Body: Introduction: Breast cancers exhibit cellular heterogeneity, containing both stem-like and more differentiated cells. The activity of cancer stem cells (CSC) is likely to be dependent on the microenvironment or niche. Using 158 patient tumour samples, correlations between niche-independent breast CSC activity and clinical and tumour characteristics were tested.

Methods: 104 early breast cancer surgical samples and 54 unrelated metastatic samples from pleural or ascitic fluid were harvested. To test CSC activity, isolated cells were grown in both primary (formation) and secondary (self-renewal) mammosphere (MS) culture. Tumour initiating activity was also tested by transplanting breast cancer fragments or cells into the sub-cutaneous flanks of NSG mice (n=84 early and n=10 metastatic).

Results: No correlation was found between MS growth, MS formation (%), MS self-renewal (%) or in vivo tumour initiation and breast cancer sub-type, grade, node status or Nottingham prognostic index. 33% of the samples that formed MS in vitro initiated tumours in vivo while only 9% that failed to form MS initiated tumour growth. Metastatic compared to early BC samples grew MS more frequently (53/54 compared to 81/104), and had a higher primary MS formation efficiency (1% vs 0.6%; P<0.001) although rates of MS self-renewal were similar. Tumour initiation in vivo was also more frequent in metastatic than early breast cancer samples (7/10 versus 25/84; P<0.02).

Conclusions: In summary, niche-independent breast CSC activity measured in vitro by MS assay and in vivo by xenograft growth is not directly correlated with standard clinical parameters. However, both in vitro and in vivo CSC activity are increased in metastatic samples. These results suggest that breast CSC activity is independent of other prognostic indicators but may predict for poor outcome tumours. Relapse free survival data are maturing and will be presented with analysis of primary tumour ALDH1 expression.
Title: Prostaglandin E receptor EP4 is a therapeutic target in breast cancer stem cells

Amy Fulton¹,², Namita Kundu¹, Tyler Kochel¹, Xinrong Ma¹ and Jocelyn Reader¹. ¹University of Maryland Greenebaum Cancer Center, Baltimore, MD and ²Baltimore VA Medical Center, Baltimore, MD.

Body: There is an urgent need to identify mechanisms underlying the survival of cells expressing cancer stem cell or tumor-initiating properties. The cyclooxygenase-2 (COX-2) pathway is highly expressed in many breast tumors and contributes to poor outcomes. The COX-2 product prostaglandin E2 (PGE2) promotes tumor growth and metastasis by acting on the G-protein-coupled receptor EP4. We compared the expression and function of COX-2 and EP4 in mammosphere-forming and bulk populations derived from a panel of human and murine luminal and basal type tumor cells with different metastatic capacities. Expression of both EP4 and COX-2 were markedly increased in mammosphere-forming cells derived from basal and/or metastatic cells relative to the bulk population, but neither COX-2 or EP4 levels were elevated in mammospheres derived from luminal or non-metastatic cells. Breast cancer stem cells, expressing elevated EP4 are correspondingly more sensitive to inhibition with EP4 antagonists both in vitro and in limiting-dilution assays in vivo. Somewhat to our surprise, cancer stem cells remain relatively sensitive to lysis by Natural Killer cells. We have also shown that EP4 blockade protects NK cells from tumor-induced immune suppression. These studies identify EP4 as a potential therapeutic target in the general tumor cell population and show that EP4 targeting may selectively inhibit cells with tumor-initiating or stem cell properties. EP4 antagonists can directly inhibit cancer stem cells and tumor metastasis and indirectly support NK-mediated mechanisms of tumor control. We are delineating the mechanisms by which EP4 and COX-2 are upregulated in cells with stem-like properties. In addition to EP4 and COX-2, STAT3 is upregulated in stem cells. Inhibition of STAT3 reduces mammosphere-forming capacity. Our studies support a mechanism whereby COX-2/EP4 signaling induces STAT3 to support breast cancer stem cell survival by a feed-forward mechanism.
Title: Proteosome inhibitor bortezomib inhibits NFκB and effectively overcomes cancer stem cell escape triggered by Wnt inhibitor therapy in FOXC1+ basal-Like/claudin-low breast cancer

Partha S Ray1,2, Connie Y Tsai2, Tania Ray3, Bomy Kim2 and Tor W Jensen2. 1University of Illinois College of Medicine, Urbana Champaign, IL; 2Carle BioMedical Research Center, Urbana, IL and 3Oracle Biosciences, Champaign, IL.

Body: Cancer stem cells (CSCs) are considered to be an important contributing factor towards treatment failure, cancer recurrence, and mortality. CSCs are known to be more enriched in the basal-like and claudin-low subtypes of breast cancer. The Wnt/β-catenin signaling pathway is well known as a regulator of embryonic development and stem cell biology, and is prominently active in basal-like and claudin-low breast cancers. We have previously reported that transcription factor FOXC1 plays a critical role in mediating aggressive cell traits in basal-like/claudin-low breast cancer. In this study, we sought to investigate the link between Wnt signaling and FOXC1 and its potential in regulating CSC biology in basal-Like/claudin-low breast cancer. We observed that exposure of the MDA-MB-231 basal-like/claudin-low cell line (low constitutive FOXC1 expressor) to Wnt3a (a canonical Wnt signaling ligand), resulted in increased expression of FOXC1. Reciprocally, overexpression of FOXC1 in MCF10A human mammary epithelial cells led to a pronounced increase in Wnt signaling activity, strongly suggestive of a direct or indirect positive feedback loop between Wnt signaling and FOXC1. More importantly, BT549 and HS578t basal-like/claudin-low cells (high constitutive FOXC1 expressors) proved to be more sensitive to treatment with the Wnt inhibitor ICRT3 as evidenced by decreased cell viability when compared to MCF7 (luminal) or SKBR3 (HER2) breast cancer cell lines. Furthermore the decrease in cell viability appeared to be proportionate to the level of FOXC1 expression. Upon pharmacological inhibition with ICRT3 and biological inhibition with siRNA knockdown of LRP6, (a canonical Wnt signaling cell surface receptor) a decrease in FOXC1 expression level was observed in a dose and time dependent manner. This effect was particularly pronounced in mammosphere cultures enriched for BT549 cancer stem-like cells. Inhibition of Wnt signaling reduced mammosphere formation efficiency of BT549 cells, suggesting that Wnt inhibition targets cancer stem cells (CSCs) in the basal-like/claudin-low breast cancer subtype. More importantly, however, after an initial 4 day incubation period, some cells are observed to persist and later display renewed enhancement of mammosphere formation ability. Profiling of such cells interestingly revealed depletion of FOXC1+ve cells but persistence of cells displaying pronounced up regulation of stereotypical embryonic stem cell Transcription Factors OCT4, SOX2 and NANOG, strongly suggestive of a potential primitive stem cell/quiescent cell state escape mechanism. qRT-PCR based pathway activation analysis revealed marked activation of NFκB signaling in the residual cells that withstood Wnt inhibition. Simultaneous pharmacologic inhibition with Wnt inhibitor ICRT3 and the proteasome inhibitor Bortezomib (known to inhibit NFκB signaling) effectively targeted BT549 cancer stem cells in mammosphere culture and prevented the persistence/emergence of any residual cells. Taken together, our findings suggest that combination therapy approaches are likely required to effectively target breast cancer stem cells.
Title: Expression of the pluripotency transcription factor SOX2 in primary breast cancers (BCs): Correlation with clinicopathological features (CPfs) and recurrence

Barbara Pistilli1, Giovanni Benedetti1, Mauro Finicelli2, Tiziana Squillaro2, Andrea Marcellusi3, Tommasina Biscotti4, Alfredo Santinelli4, Paola Mariani5, Paolo Decembrini5, Giancarlo Ciccioli6, Luciano Latini1, Antonio Giordano8 and Umberto Galderisi9.

1Macerata Hospital, Macerata, Italy; 2Human Health Foundation, Spoleto, Italy; 3University of Rome “Sapienza”, Rome, Italy; 4Politecnica University of Marche, Ancona, Italy; 5Macerata Hospital, Macerata, Italy; 6Civitanova Hospital, Civitanova Marche, Italy; 7Macerata Hospital, Macerata, Italy; 8Sbarro Institute for Cancer Research and Molecular Medicine, Temple University, Philadelphia and 9Second University of Naples, Naples, Italy.

Body: BACKGROUND
SOX2 is one of the pluripotency transcription factors expressed by stem cells, which plays a central role in controlling the expression of genes implicated in embryonic development and stemness maintenance. Key regulators of embryonic stem cell (ESC) identity, such as NANOG, SOX2, OCT4 and GDF3 resulted overexpressed in a variety of solid tumors with a possible role in cancer progression and prognosis. SOX2 expression has mainly been reported in basal-like BC subtype, suggesting a role in conferring a less differentiated phenotype. In our analysis we evaluated a heterogeneous group of BC tissues to determine whether the expression of ESC-regulating genes correlated with CPfs and recurrence.

METHODS
140 primary invasive BC specimens were collected from 137 female patients who underwent surgery. mRNA expression for SOX2, OCT4, NANOG, GDF3 genes was assessed by RT-PCR. Immunohistochemistry (IHC) was performed for SOX2 with mouse monoclonal antibody (1:50, Y17, Santa Cruz Biotechnology, USA). Correlations with molecular subtypes, menopausal status, grading, ER, PR, ki67 (≤ 20% and > 20%), HER2, T-size and node status were evaluated by Fisher's exact test and χ2 test. Association of ESC-genes, CPfs and DFS was estimated by univariate and multivariate Cox-regression analysis (p ≤ 0.05). Survival analysis (DFS and OS) were calculated by Kaplan-Meier curves and compared by log-rank test.

RESULTS
In 117 samples assessable by RT-PCR the genes resulted expressed as follows: NANOG=52 (44.5%), SOX2=11 (9.4%), GDF3=9 (7.2%), OCT-4=0. Correlation of mRNA gene expression with CPfs was statistically significant between NANOG and grade 2, GDF3 and node-negative status, SOX2 and higher ki67 (p=0.019, p=0.029, p= 0.035, respectively). Six out of 11 SOX2+ tumors were HER2+ (data not statistically significant); in the remaining 5 samples the fluorescence in situ hybridization was performed but no HER2 amplification was detected. At univariate analysis of DFS, SOX2 expression (HR=2.36; p=0.002), ki67 (HR= 2.19; p=0.028), T-size ≥1 (HR=2.06; p=2.011), node-status (HR=2.21; p= 0.014), ER/PR (HR=0.58/HR=0.59, p=0.065/p=0.068) resulted statistically significant. At multivariate analysis, SOX2 (HR=2.99; 95% CI 1.41-6.30; p=0.004), node-status (HR=2.44; 95%CI 1.25-4.76; p=0.009) and T-size ≥1 (HR=1.77; 95% CI:0.99-3.13; p=0.051) were independently associated with increased risk of recurrence. An earlier recurrence was observed in SOX2+ patients (median 34.9 months; 95% CI: 7.5-62.2) than SOX2- patients (median: 60.3 months; 95% CI: 32.6-88.1) (p=0.017); OS resulted shorter in SOX2+ (68.2 months 95%CI: 63.7-151.4 vs 145.3 months 95% CI: 80.5-210.2) albeit not statistically significant (p=0.104). IHC analysis showed a positive score for SOX2 protein expression in all of 11 samples with SOX2 mRNA amplification; SOX2+ protein was not detected in 20 samples randomly selected among the tissues not expressing SOX2 mRNA.

CONCLUSIONS
Our analysis confirm that ESC-regulating genes correlate with specific CPfs (grading, node-status and ki67). Notably, SOX2 resulted to be an independent prognostic factor, as it was associated with a risk of recurrence increased by 3 times, irrespective of other CPfs.
Title: Mammospheres derived from circulating epithelial tumor cells are an indicator for presence of metastasis in patient with breast cancer

Monika Pizon\textsuperscript{1}, Dorothea Zimon\textsuperscript{1}, Ulrich Pachmann\textsuperscript{1} and Katharina Pachmann\textsuperscript{1}. \textsuperscript{1}Transfusion Center, Bayreuth, Germany.

Body: Background:
A major obstacle in the successful treatment of cancer is the occurrence of metastasis. The presence of CETCs is closely related to tumor recurrence, but the mechanisms through which CETCs promote metastasis are still unclear. The aim of this study was to determine the proliferative capacity of CETCs by analyzing the frequency of mammosphere formation with subsequent phenotypic characterization of the spheres arising in breast cancer patients.

Methods:
CETCs were cultured under condition favoring growth of mammospheres from 38 patients with breast cancer, including a subpopulation of 13 patients with metastatic disease. Cell viability, stem cell marker expression and ALDH 1 activity was evaluated by fluorescence scanning microscope (Olympus Scan®R).

Results:
Sphere formation was observed in 74\% of patients with breast cancer. Patients with distant metastasis had higher numbers of mammospheres (median 13.0 vs 1.0; \(p \leq 0.001\)) compared to patients without metastasis. In multivariate analysis, a high number of mammospheres was associated with the presence of metastasis. The mammospheres area under the ROC curve was 0.99. Six or more spheres classified metastatic disease with a sensitivity and specificity of 96\% and 100\%, respectively. These results suggest that above cut-off six in the number of mammospheres is statistically highly indicator for disease progression. Analysis of surface marker expression profile of mammospheres showed that spheres cultured from CETCs had typical phenotype of cancer stem cells with a high enzymatic activity for ALDH 1 with the ALDEFLUOR assay. There was no sphere formation in a control group with 50 healthy donors.

Conclusion
This study demonstrates that a small fraction of CETCs has proliferative activity. Identifying the CETC subset with cancer stem cells properties may provide more clinically useful prognostic information and may be a new indicator for the presence of metastases.
Title: StemScreen®, an innovative platform technology for the identification of novel cancer stem cell-directed compounds

Janice Chen¹, Hai Li², Marcie A Glicksman³, Charles Karan², Christopher Brooks¹ and Eric K Rowinsky¹. ¹Stemline Therapeutics, Inc, New York, NY; ²Columbia University Medical Center, New York, NY and ³Brigham and Women's Hospital, Cambridge, MA.

Body: Cancer stem cells (CSCs) are thought to play significant roles in breast cancer initiation and progression. Conventional therapeutic agents target tumor bulk but spare CSCs, leading to tumor recurrence and relapse. Therefore, drugs that eliminate both tumor bulk and CSCs may represent the most effective treatment strategy for breast cancer. We have developed a proprietary cell-based screen called StemScreen® that permits the rapid testing and identification of novel CSC-directed compounds in a high-throughput manner. StemScreen® takes advantage of a landmark discovery that many cancer cell lines harbor stable populations of CSCs. Our initial studies utilized a breast cancer cell line transfected with a unique expression vector that is only active in the 1-5% putative CSC population. The StemScreen® platform is unique because it allows for screening of compounds within the context of the CSCs’ natural microniche environment and has advantages over traditional drug discovery methods that have been designed to identify compounds that only target tumor bulk, but not CSCs.

In an effort to increase the throughput and make the assay compatible with existing compound libraries, we miniaturized the platform to a 384-well format and optimized the line for high-content screening. A series of compound hits identified from screening these cells against smaller libraries of known active compounds as well as larger and more diverse compound libraries will be presented. We are also currently expanding this technology into other tumor types. We believe that this approach represents a major technological advance in oncology drug discovery and that this platform will be instrumental in the discovery of unique new therapies that have a dual effect on CSCs and non-CSC tumor bulk.
Title: SIRT1 inhibitors significantly reduce cancer stem cells and block epithelial mesenchymal transformation in breast cancer cells

Songlin Zhang¹, Min Li¹, Baoxiang Guan¹ and Robert Brown¹. ¹UTHSC at Houston, Houston, TX.

Body: Breast cancer stem cells are contribute to distance metastasis, breast cancer recurrence and drug resistance. SIRT1, a nicotinamide adenine dinucleotide (NAD⁺)-dependent histone deacetylase, play significant role in DNA repair, cell survival, stem cells and epigenetic modification. SIRT1 has been related to cancer stem cells in chronic myelogenous leukemia. In this study, we investigate the role of SIRT1 in breast cancer stem cells.

SIRT1 inhibitors cambinol and Ex527 are used for treatment in several breast cancer cell lines, including T47D, TB549, MDA-MB-231 and MDA-MB-468. Stem cell markers, SOX-2 and Nanog, are significantly decreased in SIRT1 inhibitor treated cancer cells by qRT-PCR and western blot in T47D cell line. The ALDH positive cells in MDA-MB-231 cell line are significant reduced from 29% to 3.2% with Adeflour assay, and the CD44 expression is significantly reduced in CD44/CD24 flow cytometry analysis. Using qRT-PCR, SIRT1 inhibitors significantly down regulate vimentin (-3.7 folds), N-cadherin and smooth muscle actin (-2.7 folds) and up regulate the gene of E-cadherin, indicating SIRT1 inhibitors can block the epithelial mesenchymal transformation (EMT) of breast cancer. SIRT1 inhibitors can significantly (40-50%) block the cancer cell invasion and migration in several triple negative breast cancer cell lines. SIRT1 inhibitors can inhibit cell proliferation on all tested breast cancer cell lines, and can induce significant cell apoptosis in T47D cells. In xenograft tumor study, SIRT1 inhibitor cambinol can significantly reduce tumor growth and inhibit tumor metastasis.

The molecular mechanism of SIRT1 inhibitors in blocking EMT and reducing cancer stem cells is likely associated with blocking the Wnt pathway. Several down stream target genes of Wnt pathway, such as cyclin D1, c-Myc and c-Jun, are significantly down regulated after using SIRT1 inhibitor cambinol, and the changes are more significant in TGF-beta stimulated cancer cells. Beta-catenin is significantly reduced including the active beta-catenin, and the decreasing beta-catenin protein may be related to the decreased Dvl proteins.

In summary, our study demonstrated that SIRT1 inhibitors can reduce breast cancer stem cell population in several cancer cell lines, block epithelial mesenchymal transformation, and inhibit breast cancer cell invasion and metastasis. SIRT1 inhibitors appear to inhibit Wnt pathway in cancer cells to block EMT and affect cancer stem cells.
Title: Inflammation promotes stem-like characteristics and increases stemness of breast epithelial cells

Jennifer Sims-Mourtada¹,², Kimberly M Arnold¹,², Lynn Opdenaker¹,³ and Daniel Flynn¹,². ¹Center for Translational Cancer Research, Helen F. Graham Cancer Center, Christiana Care Health Services, Inc, Newark, DE; ²University of Delaware, Newark, DE and ³University of Delaware, Newark, DE.

Body: Triple negative breast cancer (TNBC) accounts for approximately 15% of all breast cancers and is more likely to affect younger women, women of African American descent, and BRCA1 mutation carriers. TNBC is typically an aggressive cancer and is defined as the absence of positive staining for estrogen (ER) and progesterone (PR) receptor, and a lack of amplification of HER2. Due to its receptor status, TNBC is insensitive to the conventional targeted treatment utilized in ER/PR/HER2 positive breast cancer leading to poor prognosis and early visceral metastasis with survival rates for women who relapse within 5 years of treatment being significantly lower than hormone receptor positive breast cancer. Therefore, understanding the mechanisms that drive the formation of TNBC can aid in determining targets to develop better treatment options. We investigated differences in the tumor microenvironment between TNBC and ER positive breast cancer patient tissue samples. Hematoxylin & eosin stain of invasive ductal carcinomas revealed that TNBC patients had higher amounts of tumor infiltrating leukocytes compared to ER positive breast cancers. In premalignant breast cancer patients, ER negative ductal carcinoma in situ (DCIS) patients had significantly higher infiltrating leukocytes compared to ER positive DCIS indicating that inflammation may be a contributing factor in TNBC. Research on molecular profiling of TNBC has revealed that a subset of gene expression patterns are associated with the basal-myoeptelial cells rather than the luminal cells, however, previous evidence indicates that TNBC arises from luminal progenitors which undergo an abnormal conversion to basal-like progenitors with enhanced growth and survival promoting characteristics. We propose this conversion occurs due to the presence of inflammatory signals early in tumor development which trigger a cascade of events that leads to acquisition of a basal-like phenotype in luminal progenitor cells and upregulation of stem-like properties, resulting in the formation of basal-like breast cancer/TNBC. Treatment of non-malignant breast epithelial cells with IL-6 increased sphere-forming efficiency under stem cell growth promoting conditions and an inhibitor of the IL-6/STAT3 pathway decreased ALDH enzymatic activity as measured by Aldefluor assay. Also, treatment with IL-6 downregulated the luminal marker, epithelial specific antigen (ESA), and increased the expression of the myoepithelial marker, CD49f, on the cell surface of non-malignant breast epithelial cells, indicating an increase in the basal-like cell population and a loss of the luminal cell population. Therefore, inflammation appears to be a common feature in TNBC compared to ER positive breast cancer and the presence of an inflammatory stimulus in the breast may promote the conversion of luminal to basal-like cells, promoting the upregulation of stem-like properties and development of TNBC. These data suggest that anti-inflammatory drugs could potentially be used to inhibit these events from occurring in the development of TNBC, leading to decreased tumor growth and better treatment options.
Title: The expression of aldehyde dehydrogenase1 in cytoplasm or stroma of breast cancer is associated with clinical prognosis

Xin Guan¹, Yi Dong², Aiping Shi¹ and Zhimin Fan¹. ¹Breast Surgery, Bethune First Hospital of Jilin University, Changchun, Jilin, China and ²Breast Surgery, Jilin Tumor Hospital, Changchun, Jilin, China.

Body: Background: Previous studies have shown that ALDH1 expression in breast tumor cells was associated with poor prognosis. Whether tumor microenvironment affect prognosis of breast cancer patients is unknown by far.

Aim: We performed a research to study whether ALDH1 expression in cytoplasm or stroma of breast tumors is associated with prognosis of breast cancer patients.

Methods: As many as 160 cases with invasive carcinoma were retrieved. ALDH1 staining was respectively assessed on cytoplasmic and stroma of tumour cells. Chi-square test was used to evaluate the associations between ALDH1 expression and clinical parameters. Cox proportional hazards analysis was used for relapse-free survival(RFS).

Results: There was significant association between ALDH1 expression in stroma and Age, ER.

Association between ALDH1 expression status and clinicopathological parameters

Conclusions: We conclude that ALDH1 expression in stroma might suggest the presence of Cancer stem cells in tumor microenvironment. The ALDH1 expression in cytoplasmic of breast tumors rather than in stroma was an independent factor for prognosis.

Key words: Breast cancer stem cell; ALDH1; Tumor microenvironment.
Title: Maintenance of stemness of breast cancer stem-like cells by FRS2beta, a feedback inhibitor for HER, during mammary tumorigenesis

Noriko Gotoh1,2. 1Cancer Research Institute, Kanazawa University, Kanazawa City, Ishikawa, Japan and 2Institute of Medical Science, University of Tokyo, Minato-ku, Tokyo, Japan.

Body: It is important to understand the molecular mechanisms how cancer stem cells (CSC)s are maintained. We examined how HER/ErbB signaling activity is regulated in breast CSCs. We generated knockout mice of FRS2beta adaptor protein, a feedback inhibitor for HER, and crossed them with MMTV-ErbB2 mice in which overexpression of ErbB2 induces breast cancer. Tumor growth in the breast tissues of wild-type mice was much faster than those of the FRS2beta mutant mice. Sphere forming activity of tumor cells was reduced in the FRS2beta mutant mice, suggesting that FRS2beta is important for maintenance of breast CSCs. Moreover, sphere forming activity of normal mammary cells were reduced in FRS2beta mutant mice. Finally, FRS2beta is strongly expressed in CSC-enriched population in human samples. It thus appears that FRS2beta is expressed in luminal progenitor cells that are transformed into breast CSCs. Fine-tuning of HER signaling by FRS2beta may play important roles for maintenance of CSCs. Further molecular details how FRS2beta contributes to mammary tumorigenesis including maintenance of breast cancer stem-like cells will be presented.
Clinical relevance and biological properties of oligometastatic breast cancer in lung; prognostic impact of CD44+/CD24−/low cells

Rei Mimoto1, Tadashi Kobayashi1, Yoshimi Imawari1, Makiko Kamio1, Kumiko Kato1, Hiroko Nogi1, Yasuo Toriumi1, Ken Uchida1 and Hiroshi Takeyama1. 1Jikei University School of Medicine, Tokyo, Japan.

Body: Background: Metastatic breast cancer is a systemic disease. Our aim was to evaluate the clinical outcomes of pulmonary metastasectomy of recurrent breast tumors and to identify possible prognostic factors.

Methods: We reviewed data from a registry of patients with lung metastases from breast tumors who received pulmonary metastasectomy in Jikei University Hospital between 2004 and 2011. We analyzed prognostic factors for overall survival (OS) and progression free survival (PFS) after metastasectomy. We also investigated lung metastases for the prevalence of CD44+/CD24−/low tumor cells and evaluated their prognostic significance.

Results: Among 17 patients with lung metastasis of breast tumors, 5-year OS and PFS were 72% and 36%, respectively. Better OS was observed among patients with oligometastatic breast cancer (OMBC). Patients with OMBC, estrogen receptor (ER) positive cells, and disease free intervals (DFI) of >8 years had better PFS. The average prevalence of CD44+/CD24−/low tumor cells in lung metastases of breast cancer was 21%, ranging from 0 to 90%. The presence of CD44+/CD24−/low tumor cells influenced the progression after lung metastasectomy, with median PFS times of only 6 months in patients with high-prevalence of cancer-initiating cells. CD44+/CD24−/low cells with cancer-initiating properties were present in only 9% ± 12 of patients with OMBC but were found in 73% ± 21 of patients with non-OMBC.

Conclusion: Pulmonary metastasectomy may be a treatment option for OMBC patients with lung metastases. Better prognosis of OMBC may be related to low levels of cancer-initiating cells.
Title: Post transcriptionally regulating LMO2, a highly expressed gene in breast cancer stem cells, to study its invasive and metastatic properties in breast cancer

Lazaro J Mesa. Stanford University, Stanford, CA.

Body: Aggressive breast cancer intrinsically possesses many epithelial-mesenchymal transition (EMT) characteristics and cancer stem cell (CSC)-like features, suggesting that activation of EMT mechanisms generate a higher degree of invasiveness in cells with CSC-like properties. The aim of this study is to test whether LIM domain only 2 (LMO2) is implicated in the degree of invasiveness of CSC-like cells. LMO2 is an important regulator of hematopoietic stem cells and sustained expression in T-cells leads to leukemia. We found that LMO2 is expressed in mammary stem cells and in breast cancer stem cells (BCSCs). To test the functional role of LMO2 in cancerous human cell lines we designed lentiviral shRNAs to knockdown the expression of LMO2 through posttranscriptional gene silencing, a form of RNAi. shRNA sequences were verified and then used to infect breast cancer cell lines. The cells were sorted based on expression of GFP and RNA was isolated from these cells. To quantitatively demonstrate a knockdown of LMO2 we performed Real Time-PCR. We were able to generate as much as a 61 percent knockdown in our infected cells relative to those with no RNA interference. These shRNA constructs will then be used to infect patient derived xenografts to test the in vivo effects of LMO2 knockdown in breast cancer stem cells; specifically, their role in the development and propagation of the primary tumor. Further understanding how LMO2 is implicated in BCSCs will lead to development of fundamental data and knowledge as to how BCSCs develops; potentially translating to clinical treatments such as gene therapy for breast cancer patients.
Title: The impact of ALDH1 on chemo-resistance and prognosis according to intrinsic subtype in breast cancers

Kumiko Kida¹, Takashi Ishikawa², Akimitsu Yamada¹, Kazutaka Narui², Sadataka Sugae¹, Mikiko Tanabe², Yasushi Ichikawa¹ and Itaru Endo¹. ¹Yokohama City University Graduate School of Medicine, Yokohama, Kanagawa, Japan and ²Yokohama City University Medical Center, Yokohama, Kanagawa, Japan.

Body: [Background]Aldehyde dehydrogenase 1 (ALDH1) has been identified as a breast cancer stem cell marker. The clinical significance of ALDH1 as a chemo-resistant and prognostic indicator has been reported recently. However, the analysis according to each intrinsic subtype was not reported.

[Aims] To investigate the impact of ALDH1 on chemo-resistance and prognosis according to intrinsic subtypes in invasive breast cancers.

[Methods]
1) Patients and tumor specimens; A total of 653 primary breast cancer patients were enrolled in this study from 2004 to 2013 at the Yokohama City University Medical Center in Japan. We performed immunohistochemical analyses using paraffin-embedded core needle biopsy sections prior to the treatment.

2) Correlation of ALDH1 with clinicopathological factors;
Analyses were performed to investigate association of ALDH1 expression with other biomarkers and clinicopathological factors in breast cancers. Age, histologic type, tumor size, nodal status, ER/PgR/HER2 status, nuclear grade, Ki67, Topo2, p53, CK5/6 and EGFR were observed.

3) Neoadjuvant patient cohort study
234 breast cancer patients receiving neoadjuvant chemotherapy were enrolled. The correlation between ALDH1 and pathological complete response (pCR) rate was investigated in each intrinsic subtype.

4) Prognostic cohort study
We performed a Cox analysis of disease free survival and overall survival of all 653 cases according to each subtype, taking account of clinicopathological factors.

[Results]
ALDH1 expression in tumor cells was seen in 139 of 653 cases (21.3%). The ALDH1 expression correlated significantly with tumor size, clinical node metastasis, clinical staging, nuclear grade and HER2 status positively, ER and PgR status negatively. ALDH1 expression was significantly seen in HER2-positive cancers and triple negative type.

In neoadjuvant study, we analyzed 234 patients treated with neoadjuvant chemotherapy including 63 luminal type, 20 luminal-HER2 type, 45 HER2-enriched type and 106 triple negative type. The pCR rate was significantly lower in patients with ALDH1-positive cases (13.5% vs. 30.3%, p=0.003). In multivariate analysis, ALDH1 and ER are correlated with pCR rate significantly. According to the intrinsic subtypes, the correlation between pCR and ALDH1 expression was extremely significant in triple negative type (p=0.003). In HER2 positive type, ALDH1 expression had tendency with low pCR, but with no significance. In luminal type, two patients achieved pCR and both had no ALDH1 expression.

In prognostic analysis, patients with ALDH1 expression had significantly poor disease free survival (DFS; p<0.001) and overall survival (OS; p=0.044). In the multivariate Cox regression model, ALDH1 expression was an independent prognostic indicator of DFS (p=0.033), but not significant predictor of OS (p=0.124). According to each intrinsic subtypes, ALDH1 had a higher impact on prognosis of luminal type, though not significant on triple negative type.

[Conclusions]
Breast cancers with ALDH1 expression posse biologically aggressive phenotypes that tend to have a poor prognosis. Chemoresistance was significantly seen in ALDH1-positive triple negative type, on the other hand, impact on prognosis was seen in luminal type more highly than triple negative type.
**Title:** EMT activates PERK-eIF2α signaling and sensitizes cells to perturbations in endoplasmic reticulum function

Yuxiong Feng¹, Ethan S Sokol¹,², Catherine A Del Vecchio¹, Sandhya Sanduja¹, Jasper HL Claessen¹, Theresa A Proia¹, Dexter X Jin¹,², Ferenc Reinhardt¹, Hidde L Ploegh¹,³, Qiu Wang³ and Piyush B Gupta¹,²,⁴,⁵,⁶. ¹Whitehead Institute for BioMedical Research, Cambridge, MA; ²Massachusetts Institute of Technology; ³Duke University; ⁴Koch Institute for Integrative Cancer Research; ⁵Harvard Stem Cell Institute and ⁶Broad Institute.

**Body:** Epithelial-to-mesenchymal transition (EMT) plays an important role in cancer progression. By undergoing an EMT, cancer cells acquire a spectrum of malignant properties, including invasiveness, multi-drug resistance and stem-like traits. Although they play an important role in tumor progression and resistance, few vulnerabilities of EMT cancer cells have been reported to date. To identify specific vulnerabilities of EMT cells, using small molecule and RNAi screens, we have discovered that induction of EMT greatly sensitizes cells to agents that perturb endoplasmic reticulum (ER) function. This unexpected sensitivity to ER stress is mainly due to the expression and secretion of large amount of extracellular matrix (ECM) proteins by cells that have undergone an EMT. In line with their increased secretory load, EMT cells display a branched ER morphology and constitutively activate the PERK-eIF2α branch of the unfolded protein response (UPR). Using a PERK-specific inhibitor, we found that PERK activation is also required for EMT cells to invade and metastasize. In human tumor tissues, EMT gene expression correlates strongly with both ECM and PERK-eIF2α genes. In summary, our findings identify a novel vulnerability of cells that have undergone an EMT, and demonstrate that the PERK branch of the UPR is required for their malignancy.
Title: IGF1R/FAK crosstalk is essential for epithelial-to-mesenchymal transition (EMT), migration, and invasion of TNBC cells

LaTonia D Taliaferro-Smith¹, Elaine Oberlick², Tongrui Liu¹, Tanisha Z McGlothen¹ and Ruth O'Regan¹. ¹Winship Cancer Institute of Emory University, Atlanta, GA and ²Harvard Medical School, Boston, MA.

Body: Triple negative breast cancers (TNBCs) are highly metastatic and deadly tumors that currently lack effective prevention and treatment options. Insulin-like growth factor 1 receptor (IGF1R) and focal adhesion kinase (FAK) both play a role in several developmental processes, and both IGF1R and FAK signaling pathways have been linked to a number of common pathological diseases, including breast cancers. In particular, overexpression of IGF1R and FAK are closely associated with metastatic breast tumors. However, the relationship between the IGF1R and FAK signaling cascades in metastatic TNBCs remain largely unknown. The present study aimed to investigate the interrelationship between IGF1R and FAK crosstalk in regulating the malignant properties of TNBC cells. Using stable small hairpin RNA (shRNA)-mediated IGF1R silencing and stable full-length IGF1R plasmid over-expression methods, we demonstrated that IGF1R was essential for maintaining mesenchymal morphologies of TNBC and regulating the expression of EMT markers, including vimentin, ZEB-1, Snail-1, E-cadherin, ZO-1, and claudin-1. Using colony formation, spheroid migration, and Matrigel invasion assays, we further showed that IGF1R promoted migratory and invasive TNBC phenotypes, including increased colony formation, cell migration, and invasion. Most importantly, IGF1R-mediated migration and invasion required FAK activation and could be augmented using pharmacological inhibitors of FAK. Our findings in TNBC cells demonstrate a novel role of the IGF1R/FAK signaling pathway in regulating critical processes involved in the metastatic cascade. These results may improve the current understanding of the basic molecular mechanisms of TNBC metastasis and provide a strong rationale for co-targeting of IGF1R and FAK as therapy for mesenchymal TNBCs.

Title: Pax-5 regulates EMT and MET in breast cancer through FAK1 regulation

Sami Benzina¹, Pierre O'Brien¹, Annie-Pier Beauregard¹, Roxann Guérrette¹, Stéphanie Jean¹ and Gilles Robichaud¹. ¹Université de Moncton, Moncton, NB, Canada.

Body: Metastasis accounts for 90% of deaths in breast cancers patients. Therefore, the study of genetic factors regulating cancer malignancy is a top priority to mitigate the morbidity and mortality associated to this disease. One of these factors, Pax-5, normally regulates key biological functions such as cell viability, growth, and differentiation. However, an aberrant expression of this factor results in the development and progression of cancer.

In this study, we developed breast cancer cell models with conditioned expression of the Pax-5 to evaluate signaling pathways relevant to breast metastasis and cancer progression. We found that Pax-5 extinguishes several aspects of cancer aggressivity such as: proliferation, spheroid formation, migration and invasion. At the molecular level, we found that Pax-5 modulates cancer malignancy through the regulation of various components of the epithelial to mesenchymal transitioning (EMT) process in addition to key signaling targets such as: NFκB and the Focal Adhesion Kinase 1 (FAK1). We also demonstrate that Pax-5 decreases FAK1 level trough up-regulation of miR-135b, a direct repressor of FAK1 expression. Altogether, our findings suggest that the presence of the Pax-5 lead to less aggressive breast cancers by promoting mesenchymal to Epithelial transitioning (MET). These findings bring light to molecular mechanisms driving breast cancer malignancy and benefit our quest in the development of diagnostic and therapeutic strategies against breast cancer progression.
Title: Treatment of metastatic breast cancer using two nanoparticles combined with siRNA targeting Twist1 to inhibit EMT

James B Finlay¹, Cai M Roberts¹, Gina Lowe¹, Ling Peng³, Jeff I Zink², Fuyuhiko Tamanoi² and Carlotta A Glackin¹. ¹City of Hope Beckman Research Institute, Duarte, CA; ²University of California, Los Angeles, CA and ³Aix-Marseille University â€“ Centre Interdisciplinaire de Nanoscience de Marseille, Marseille, Provence-Alpes-Côte d’Azur, France.

Body: Breast cancer is the 2nd leading cause of cancer related deaths among women in the US with over 240,000 diagnoses and 40,000 deaths expected in 2014. Among the more serious and deadly forms of breast cancer are the Triple Negative Breast Cancers (TNBC) (ER-, PR-, HER2-). Mortality rates among patients rise dramatically when these cancers spread beyond the primary tumor site. Therefore reduction of tumor cell dispersion is a key component to minimizing mortality rates. Epithelial-Mesenchymal Transition (EMT) is the process by which cancer cells downregulate proteins associated with cell to cell adhesion (e.g. E-cadherin) resulting in cells that are able to detach from neighboring cancer cells, invade adjacent tissue, and eventually enter the circulatory system or lymphatics. The process of EMT is tightly regulated by the transcription factor Twist1, which is often overexpressed in breast cancer. Therefore, Twist1 serves as an excellent therapeutic target whose downregulation would result in fewer metastatic cancer cells and correspondingly reduce cancer mortality.

Our lab has designed and tested (in vitro) two siRNA based therapeutics that target Twist1 in a TNBC cell line (SUM 1315). These siRNA molecules have been strategically designed and modified to make them resistant to degradation, enhance silencing effects and diminish their immunogenicity. To overcome the inherent problems with delivery of siRNA (both in vitro and in vivo) we have been testing two nanoparticle delivery systems. Recent advances in nanotechnology have led to the development of a variety of nanoparticles that provide valuable tools for cancer therapy. We are testing two different types of nanoparticles in this study: The first is a Polyamidoamine (PAMAM) dendrimer (YTZ3-15) which is a truncated 3rd generation dendrimer which has been modified with a lipophilic tail to enhance cellular uptake. The second is a mesoporous silica nanoparticle (MSNs) which is able to not only deliver siRNA, but is also contains pores which allow simultaneously delivering chemotherapies such as doxorubicin. This novel siRNA gene silencing and nanotechnology-based therapy should allow us to exert more precise temporal control during breast cancer treatment.

When complexed with either nanoparticle we have found significant Twist1 knock down in vitro as well as reduction of Twist1 target genes that are associated with EMT. We have also shown that Twist1 silencing reduces migration and invasion of SUM 1315 breast cancer cells in vitro Recently we began testing these siRNA+Nanoparticle complexes in an orthotopic murine model using Firefly Luciferase expressing SUM 1315 cells in immunocompromised mice (NSG). The results of this in vivo research have shown that there is significant uptake of the siRNA+Nanoparticle complexes in the tumors when compared to other organs. Results of these studies are significant because TNBC is particularly drug resistant and metastatic; and superior therapies are urgently needed to effectively treat patients with these breast cancers. This approach paves the way for TNBC treatment that incorporates Twist1 knock down (resulting in renewed chemosensitivity) and simultaneous delivery of a chemotherapy reagent.
Title: A potential role for Janus protein tyrosine kinases in the regulation of epithelial-mesenchymal transition in a model of epidermal growth factor induced breast cancer epithelial-mesenchymal transition

Teneale A Stewart¹, Iman Azimi¹, Felicity M Davis¹, Erik W Thompson²,³,⁴, Andrew J Brooks⁵, Sarah J Roberts-Thomson¹ and Gregory R Monteith¹. ¹School of Pharmacy, University of Queensland, Woolloongabba, Queensland, Australia; ²St Vincent's Institute, Fitzroy, Victoria, Australia; ³University of Melbourne, St Vincent's Hospital, Fitzroy, Victoria, Australia; ⁴Institute of Health and BioMedical Innovation and School of BioMedical Sciences, Queensland University of Technology, Kelvin Grove, Queensland, Australia and ⁵Institute for Molecular Bioscience, University of Queensland, St Lucia, Queensland, Australia.

Body: Background. Epithelial-mesenchymal transition (EMT), a process whereby tumorigenic epithelial cells acquire an invasive and migratory phenotype, is an important event in the invasion-metastasis cascade. As such, intracellular signaling pathways involved in the regulation of EMT represent potential therapeutic targets in the treatment and prevention of invasive cancer subtypes. The calcium ion, a highly versatile intracellular messenger, plays an important role in processes important in tumorigenesis including invasion and metastasis, and altered calcium signaling has been identified in various cancers. We recently identified that activation of signal transducer and activator of transcription 3 (STAT3) and expression of specific EMT markers in the MDA-MB-468 cell line model of epidermal growth factor (EGF) induced EMT display some calcium dependence. While the calcium permeable ion channel TRPM7 was shown to partially regulate this STAT3 activation and vimentin expression, the precise mechanisms of their regulation are not yet fully understood. The aim of this research was to investigate the upstream intracellular signaling pathway involved in EGF stimulated STAT3 activation and the subsequent induction of EMT in this model.

Methods. MDA-MB-468 basal-like breast cancer cells were pre-treated for 1 hr with the Janus protein tyrosine kinase (JAK) inhibitor, JAK inhibitor I (1 and 10 µM), or the Src family tyrosine kinase inhibitor, PP2 (0.1, 1 and 10 µM), followed by stimulation with EGF (50 ng/mL) for 10 or 20 min, and 24 h to assess effects on STAT3 activation and/or EMT marker expression, respectively. Total cellular protein was isolated following inhibitor treatment ± EGF stimulation, and the level of phosphorylated STAT3 (10 or 20 min) or vimentin protein expression (24 h), was analyzed using Western blotting. Cellular RNA was isolated following inhibitor treatment ± EGF stimulation and levels of vimentin mRNA (24 h) were assessed using real time RT-PCR.

Results. Treatment of MDA-MB-468 breast cancer cells with JAK inhibitor I resulted in a significant decrease in EGF stimulated STAT3 phosphorylation, while inhibition of Src family tyrosine kinases with PP2 also significantly decreased EGF stimulated STAT3 phosphorylation. In addition to its effects on STAT3 phosphorylation, pre-treatment of MDA-MB-468 cells with JAK inhibitor I also appeared to decrease EGF-induced vimentin protein and mRNA expression, indicating a potential role for Janus protein tyrosine kinases in the induction of EMT in this model.

Conclusions. Janus protein tyrosine kinase signaling appears to play a role in the regulation of STAT3 activation, and the induction of the EMT marker vimentin in the MDA-MB-468 cell line model of EGF-induced EMT. Future studies will focus on investigating the specific JAK family member(s) involved in the EGF-STAT3 signaling pathway, as well as the nexus between calcium and identified regulators of EGF stimulated STAT3 activation, and EMT marker expression, in this model of breast cancer EMT.
Title: Niclosamid overcomes epithelial-mesenchymal transition of lapatinib resistance through inhibiting Src activation in HER2 positive breast cancer

Junjun Liu¹, Xiaosong Chen¹, Yan Mao¹ and Kunwei Shen¹. ¹Comprehensive Breast Health Center, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.

Body: Background: The Src pathway is known to regulate tumor metastasis and plays a role in epithelial-mesenchymal transition (EMT). Lapatinib, although, has improved clinical outcome for HER2 positive breast cancer patients, acquired resistance to lapatinib remains an important reason influencing its clinical efficacy. Our previous research shows lapatinib acquired resistance HER2 positive breast cancer cell lines, SKBR3-R and BT474-R have EMT phenomenon and multiple pathway activated. Niclosamide is an FDA-approved antihelminthic agent, which is found has cytotoxicity effect on tumor stem cells recently. We wished to determine the effect of niclosamide on EMT and lapatinib resistance cells and investigate niclosamide as a potential therapeutic agent for HER2 positive breast cancer.

Methods: SKBR3 and BT474, two HER2 positive breast cancer cell lines, were continuously exposed to increasing doses of lapatinib to establish two stable cell lines resistant to lapatinib, SKBR3-R and BT474-R. Cell proliferation was determined by CCK8 assay. Protein expression was determined by western blotting. Invasion ability was analyzed by transwell assay. FITC staining flow cytometry (FCM) was conducted to observe the percentage of apoptosis.

Results: Both two HER2 positive lapatinib resistant cell lines, SKBR3-R and BT474-R had EMT phenomenon. Niclosamide had a stronger inhibition effect on lapatinib resistant cell lines than parental cell lines, and induced more apoptosis by FCM. Western-blot showed niclosamide could reverse the EMT phenomenon of SKBR3-R and BT474-R with E-cadherin up-regulated and snail, vimentin down-regulated at the concentration of 0.5-1µM. A significant reduction of Src signaling was also confirmed, as well as the downstream Akt and Erk pathway. After adding niclosimide for 48 hours, SKBR3-R and BT474-R’s capability of invasion were inhibited.

Conclusion: Our results suggested that niclosamide had a strong cytotoxic effect on HER2 positive lapatinib resistant breast cancer cell lines. The EMT induced by lapatinib resistance could be reversed by niclosamide, associated with the inhibition of Src pathway activation, as well as the downstream pathways. Niclosamide treatment produced reduced levels of invasion, serving as a novel therapeutic way for lapatinib-resistant breast cancer patients.
Title: Prostaglandin E receptor 2 (EP2) regulates breast cancer stem-cell like property and promotes epithelial-mesenchymal transition

Vivian Y Shin,1 Man T Siu,1 John C Ho,1 Isabella Cheuk,1 Jiawei Chen,1 and Ava Kwong1,2. 1University of Hong Kong and 2Hong Kong Hereditary Breast Cancer Family Registry, Hong Kong.

Body: Background: Presence of cancer stem-like cells (CSCs) is the main obstacle for poor treatment response and mortality in breast cancer patients. Prostaglandin E receptors have been reported to play a role in epithelial-mesenchymal transition (EMT) and metastasis, however, the contribution on cancer stem cell compartment remains unstudied.

Methods: Human xenograft breast cancer model was used to study the expression of EP receptors during cancer development. Construction of stable EP2-expression cells was used to study tumorigenesis and characterization of EP2 receptor. Functional role of EP2 receptor on cell proliferation, flow cyometry, invasion and EMT gene expression array were performed in transfected cells. Expression of EP2 receptor was compared in primary tumor tissues by immunostaining and real-time PCR.

Results: EP2 receptor was predominantly expressed in animal tissues during cancer development, as well as in human primary tumor tissues. In mouse xenograft model, MB-231-EP2 clone developed a more aggressive tumor with a larger tumor size and showed a significant increase in cancer stem cell marker aldehyde hydrogenase (ALDH1) expression. In vitro study, MB-231-EP2 clone increased colony formation capacity and S-phase entry by the regulation of E-cadherin, TWIST1 and ALDH1. Importantly, we found that Twist1 expression level was higher in breast cancer patients than healthy controls and was associated with ALDH1 expression.

Conclusions: These findings implicated that EP2 receptor was crucial to nurture CSC phenotype and promote tumorigenesis in breast cancer. Blocking of EP2 might be a potential therapeutic strategy to improve treatment response for breast cancer patients.
Interaction of mesenchymal stem cell with breast cancer lineage cells and evaluation of their biological behavior

Fernanda Marques Rey¹, William Abraham da Silveira¹, Heriton Marcelo Ribeiro Antonio¹, Renata D Sicchieri¹ and Daniel Guimaraes Tiezzi¹. ¹Ribeirão Preto School of Medicine, Ribeirão Preto, São Paulo, Brazil.

Body: Breast carcinoma is a highly prevalent and incident disease. The interaction between tumor stroma and malignant epithelial cells has been reported as a mechanism of resistance to cytotoxic treatment. Mesenchymal cells originating from the tumor stroma create a favorable microenvironment for cancer stem cells (CTTs) maintenance. CTTs are able to repopulate the host with tumor cells of the same origin on distant sites. It is postulated that this interaction modulates the ability of tumor to invade and disseminate. The aim of this study is to analyze the association MCF-7 cell line with human mesenchymal stem cells (MSC), and evaluate the biological behavior and phenotypic changes. MSC cells derived from Wharton's jelly were co-cultured with MCF-7. Cell migration assay: MSC cells were seeded into 12 well plates and co-cultured with MCF-7 cells in the proportions 1% MSC + 99% MCF-7, 10% MSC + 90% MCF-7, 30% MSC + 70% MCF-7 and 100% MCF-7 in 5x10⁴ total cells. After 5 days of culture, two lines cross were traced on the bottom of the well. An inverted microscope with 10X objective was used to photograph at time 0 hours, 24 hours, 48 hours and 120 hours until confluence. We analyzed the phenotypic changes and mean migration time of cell culture and co-culture. The confluence of the cell layer of the area of migration occurred after 120 hours only in co-culture of MSC 30% and 70% MCF-7 (163.66Åμm to 0 μm). Flow cytometry: MSC cells were seeded into 6 well plates and co-cultured with MCF-7 cells in the same proportions as described above in 1x10⁵ total cells, and maintained at 37° C with 5% CO² for 5 days. Were quantified cells with CD44+/CD24- profile with anti-CD44 antibody (APC) and anti-CD24 (PE). The ANOVA with Tukey's post-test were used for statistical analysis. Data were presented as mean ± standard deviation, p< 0.05. There was no significant difference in CD44+/CD24- in the comparison groups: MSC vs. cell co-cultures; cell co-cultures vs. cell co-cultures; MCF-7 vs. 1% MSC+ 99% MCF-7; MCF-7 vs. 10% MSC + 90% MCF-7. We observed a significant increase in CD44+/CD24- population comparing MCF-7 vs. co-culture of 30% MSC + 70% MCF-7 (95% CI of diff, -55.56 to -27.71). Conclusions: The co-culture with MSCs an MCF-7 is associated with an increase in cell migration and, the is a increase in CD44+/CD24- cells. These findings suggest that the interaction of mesenchymal stem cells with MCF-7 may be is able to acquire potential metastatic profile.
Autoimmunity in breast carcinogenesis. A new paradigm

Félix Fernández Madrid¹,², Marie-Claire Maroun¹, Leonard Lipovich¹, Larry Tait², Azadeh Stark³, Richard Zarbo³, Lisa Polin¹ and Dhananjay Chitale³. ¹Wayne State University, Detroit, MI; ²Karmanos Cancer Institute, Detroit, MI and ³Henry Ford Health System, Detroit, MI.

Body: The B cell response in breast cancer [BC] may have a tumor-promoting effect. The objective of this work was to demonstrate that TAAs and cytokines inflict autoimmune damage to the breast creating a chronic inflammatory milieu that promotes BC progression

Methods: The DCIS.com nude mouse xenograft model of BC was treated with rituximab and dexamethasone. Immunoscreening of a cDNA library, PCR, and sequence determination. Immunohistochemistry [IHC] for inflammatory cytokines, immunoglobulins and complement and the TUNEL assay.

Results: Deposition of immunoglobulins and complement was shown on breast epithelial and stromal cells and the involvement of IL-4, IL-6, IL-17, TNF-alpha and NFkB was demonstrated by IHC staining. We identified autoantibodies recognizing multiple human breast epithelial and stromal antigens and the Fc and V regions of immunoglobulins. Rituximab and dexamethasone treatment markedly modified the macroscopic and microscopic appearance of BC and the pattern of cytokine deposition, induced increase in vascularity, marked stromal hypertrophy and massive debulking of the tumor by drastically reducing the tumor mass through apoptosis.

Conclusions: These results suggest that autoantibody- and cytokine-mediated autoimmune damage, triggered by TAAs creates a chronic inflammatory milieu with generation of pro-inflammatory and tumor promoting signals supporting BC progression. The dramatic results of the treatment of the xenograft model with rituximab and dexamethasone illustrate the potential of treating BC as a chronic rheumatic autoimmune disease. The demonstration of a major role of autoimmunity in BC progression may have a transformative impact on prevention, diagnosis and treatment of BC.
Title: Autoimmunity to centrosomal and proteasome proteins in breast cancer. A link to chromosome instability?

Marie-Claire Maroun¹, Ofelia Olivero², Judith Abrams³, Wei Chen³, Azadeh Stark⁴, Carol Peebles⁵, Larry Tait³, Dhanajay Chitale⁴ and Félix Fernández Madrid¹³. ¹Wayne State University, Detroit, MI; ²National Cancer Institute, NIH, Bethesda, MD; ³Karmanos Cancer Institute, Detroit, MI; ⁴Henry Ford Health System, Detroit, MI and ⁵INOVA Diagnostics Inc, San Diego, CA.

Body: BACKGROUND. Perturbation of centrosomal or centrosome-associated proteins has been observed in nearly all human solid tumors and has been implicated in the origin of chromosomal instability. Ubiquitin-proteasome degradation is highly dependent on the organizing capabilities of the centrosomes. Here we report that autoantibodies in breast cancer [BC] sera target centrosomal proteins as well as important proteins involved in proteasome protein degradation.

METHODS. We immunoscreened a T7 cDNA library of BC proteins and the association of the cloned autoantigens with BC was studied by autoantigen microarray analysis. We used immunohistochemistry [IHC] to investigate the expression of the centrosome and centrosome-associated autoantigens identified.

RESULTS. Immunoscreening with BC sera led to the identification of autoantibodies recognizing epitopes developing in a family of proteins located on the centrosomes such as NIMA-related kinase 7, dynein heavy chain domain 3, peri-centriolar material-1, isomorph CRA, and stathmin-1, the ubiquitin-conjugating enzyme E2, the proteasome 26S subunit and the SUMO/sentrin peptidase. Antibody reactivity to these proteins which are associated with centrosome assembly, microtubule function and protein degradation were highly associated with the diagnosis of BC. IHC staining of paraffin-embedded BC sections with specific antibodies showed that aurora and stathmin-1 and other centrosome antigens are expressed in BC.

CONCLUSIONS. The discovery of autoantibodies targeting important centrosome and proteasome proteins associated with BC suggests that this immune reactivity could be related to autoimmunity developing in BC. Our findings indicate that these autoantibodies might be biomarkers of early BC and suggest the possibility of a link with chromosomal instability in BC.
Title: The association between primary breast cancer and thyroid cancer: A meta-analysis

Kyle R Joseph¹, Senarath Edirimanne¹ and Guy Eslick¹. ¹University of Sydney, Sydney, NSW, Australia.

Body: Background: Previous studies have suggested an aetiological link between breast cancer and thyroid cancer, however, there has never been a formal meta-analysis which collates the existing evidence supporting the hypothesis that breast cancer or thyroid cancer predispose an individual to developing the other.

Method: A systematic search was carried out using the electronic databases Pubmed and Medline. We searched for articles containing epidemiological evidence of breast cancer following thyroid cancer and vice versa. Additionally, we searched for articles that included epidemiological data involving the incidence of all second primary malignancies following both breast cancer and thyroid cancer, and compared the data sets.

Results: The meta-analysis performed in a total of 18 studies, showed that there is a significantly increased risk of developing thyroid cancer as a second primary malignancy of breast cancer (RR=1.59, 95% CI: 1.28-1.99; I²=79.99, p<0.001). Additionally, there was marginally increased risk of developing breast cancer as a second primary malignancy of thyroid cancer (RR=1.24, 95% CI: 1.18-1.30; I²=24.67, p=0.18), compared to the general risk of developing a second primary malignancy following thyroid cancer.

Conclusion: The findings of this meta-analysis suggest that there is less likely to be a common aetiological factor of the two cancers, but rather a specific aspect of the pathophysiology of breast cancer which pre-disposes individuals to develop thyroid cancer. Elucidation of the common mechanisms between breast cancer and thyroid cancer will have important implications in both diagnostic and therapeutic management of these cancers. Benefit of thyroid ultrasound screening after breast cancer surgery needs to be assessed.

Title: MBC alliance: Coordinating metastatic research from lab bench to clinical trials

Marc S Hurlbert¹, Musa Mayer², Stephanie Reffey³, Elly Cohen⁴, Susan Colen⁴, Samantha Finstad⁶, Katherine McKenzie⁶, Alison Butt⁷, Ginny Mason⁸ and Lynne Davies⁹. ¹Avon Foundation for Women, New York, NY; ²AdvancedBC.org, New York, NY; ³Susan G. Komen, Dallas, TX; ⁴BreastCancerTrials.org, San Francisco, CA; ⁵National Cancer Institute, Bethesda, MD; ⁶California Breast Cancer Research Program, Oakland, CA; ⁷National Breast Cancer Foundation Australia, Sydney, New South Wales, Australia; ⁸Inflammatory Breast Cancer Research Foundation, West Lafayette, IN and ⁹International Cancer Research Partnership, London, England, United Kingdom.

Body: The Metastatic Breast Cancer (MBC) Alliance[1] consists of non-profit advocacy, funding organizations and industry partners who seek to transform and improve the lives of women and men living with MBC. There is no cure for MBC and metastasis is the cause of virtually all breast cancer deaths. One objective of the Alliance is to understand the MBC research landscape from basic lab research through translational and clinical trials, to epidemiology, quality of life and patient reported outcomes. The MBC Alliance partnered with the International Cancer Research Partnership (ICRP[2]), an alliance of governmental and charitable organizations from the USA, Canada, Europe, Australia and Japan that fund regional, national and international cancer research grants and awards. The ICRP database of member’s funded grants contains >60,000 grants since 2000, from >80 member organizations, totalling over $14 billion USD. Each project is coded to a Common Scientific Outline (CSO), a classification system of broad areas of cancer research. Objective: To review the last ten years of breast cancer research grant funding related to metastasis and clinical trials to identify the most promising molecular targets, pathways and therapeutics in development for MBC. Methods: ICRP partner-funded grants related to MBC were queried from the ICRP database and clinical trials were queried from Clinicaltrials.gov and breastcancertrials.org. We also conducted interviews with 75 experts including advocates, scientists, clinicians, and leaders of professional societies and cooperative groups. The database searches resulted in a pool of 150 open clinical trials for MBC and 17,985 breast cancer-relevant grant awards. Relevant grant awards and clinical trials were then coded with the assistance of keywords and manual review, to one or more, of 6 categories relevant to the hallmarks of cancer (Hanahan & Weinberg[4]) and metastasis (Steeg[5]). Results: The ICRP database contained 2,250 unique awards related to MBC. The awards are predominantly basic research (70%) and translational (24%) and that profile has not changed significantly over a 5-year period 2008-2012. Awards active in 2012/2013 show that the main areas of focus are: i) early steps to invasion (10%) and, ii) metastatic colonization (15%). Data from 130 trials have been assigned to the Hanahan/Weinberg framework: sustaining proliferative signal, resisting cell death, enabling replicative mortality, genome instability and mutation, tumor promoting inflammation, activating invasion and metastasis, avoiding immune destruction, and other categories like cancer stem cells. Within these categories, the molecular targets of the drugs being used in the trial were further subdivided (e.g., PI3, RAF, CDK). Of the trials analyzed, 71 were Ph I or PhI/II, 47 Ph II and 11 Ph III. Conclusion: Using publicly available databases we were able to develop a comprehensive list of molecular targets, pathways and therapeutics for MBC that will enable improved coordination of MBC research. [1] https://www.mbcalliance.org/; [2] https://www.icrpartnership.org/index.cfm; [3] CSO 1.4 (Biology of progression) and keywords associated with metastasis.; [4] Hanahan D and Weinberg RA, Cell 2011;144:646-674.; [5] Steeg PS. Nature Medicine 2006;12(8)895-904.
Body: The International Cancer Research Partnership (ICRP[1]) is an alliance of governmental and charitable organizations from the USA, Canada, Europe, Australia and Japan funding regional, national and international cancer research grants and awards. One key activity of the partnership is a database of information about member’s funded grant projects (N>60,000 grants, from 80 members, totalling over $14 billion USD). Each project is coded to a Common Scientific Outline (CSO), a classification system of broad areas of cancer research. Breast cancer is the most common cancer in women worldwide, however, only about 5-10% of breast cancer is attributable to genetic predisposition,[2] and about one third of cases are attributable to known genetic or other risk factors. In 2013, the Interagency Breast Cancer and Environmental Research Coordinating Committee (IBCERCC)[3] recommended that funding organizations plan strategically to accelerate the pace of scientific research on breast cancer and the environment. Thus, the ICRP has developed a mechanism to track activity and trends in research into environmental influences on breast cancer, to provide a baseline for future assessment of progress. Methods: ICRP-funded grants related to environmental influences on breast cancer were queried from the ICRP database. We focused on three time points: awards that were active in 2006, 2008 or 2010. The search resulted in a pool of 11983 breast cancer-relevant awards that was narrowed further to 1107 awards of relevance using a combination of keyword searches and specific Common Scientific Outline (CSO) codes.[4] Relevant awards were then coded with the assistance of keywords and manual review, to one or more, of 6 categories of environmental research: Behavior-Lifestyle, Behavior-Tobacco exposure, Chemicals-Chemical pollutants, Chemicals-Exogenous hormones, General Infection-Microorganisms and Radiation. Results: Between 2006 and 2010, the numbers of active awards declined and funding levels also fell. Most of the funded research is focused on behavioral/lifestyle factors in breast cancer (e.g., diet, alcohol intake, and shift work patterns). Further analysis of the Behavioral/Lifestyle category reveals that the major area of activity is in the role of nutrition/alcohol in cancer, closely followed by the contribution of obesity and reproductive factors (age of menarche, parity etc.). Conclusion: We were able to utilize a CSO ‘filter’ to identify trends in funded grant projects related to the environment and breast cancer. The decline in numbers and research funding between 2006 and 2010 is concerning. As breast cancer incidence continues to increase, research efforts to understand the causes of increased incidence are essential. Further research investment in these areas may be required.

Got patient advocates? The value of patient advocate participation in a large research study to develop personalized risk-based breast cancer screening strategies

Vernal Branch, Carolyn Achenbach, Kathleen G Ross, Wendy F Cohn, Martin D Yaffe, William A Knaus and Jennifer A Harvey. 1Virginia Breast Cancer Foundation, Richmond, VA; 2University of Virginia, Charlottesville, VA; 3University of Toronto, Toronto, ON, Canada and 4Northshore University Research Institute, Evanston, IL.

Body: Background: Over the last several years there has been confusion among women about breast cancer screening and patient advocates are increasingly used to help women understand the changes. In 2009, the U.S. Preventive Task Force (USPSTF) recommended that women under the age of 50 do not need routine screening. New state laws require breast density results to be given to women and their providers for making their screening choices. Women are not sure what to do with this information and are offered little guidance to personalize their screening recommendations. The goal of this study is to develop a risk model for improved personalized breast cancer screening recommendations. Patient advocates were incorporated throughout the design, recruitment, analysis, and dissemination phases of the study.

Methods: The research team included three patient advocates who participated as full members in the bi-weekly and quarterly team meetings throughout the duration of the study. All advocates were breast cancer survivors. The primary components of the study included focus groups to understand women’s knowledge and views on breast density as well as personalized screening, a telephone survey to gain a broader view on these topics, and recruitment to a case:control study to build a breast cancer risk model that incorporates an automated measure of breast density.

Results: Enrollment was completed over one year with 3,445 women; 839 cases and 2,606 controls. Study design and resulting recruitment strategies were reviewed early with regular feedback by the patient advocates. At the advice of the advocates, Facebook was chosen as primary social media, resulting in nearly 200 posts (stories) and 1583 likes for the project. Many of the posts were generated by or featured advocates. Regarding the focus groups, the advocates developed the questions. Women were informed about the study by the advocates and educated about breast density. The advocates were key in using the focus groups to find the right language for enrollment materials, obtain their perception of the importance of the study, and understand their views regarding a new model for personalized screening for women. The advocates were likewise key in developing questions for and analyzing results of the telephone survey. In the analysis phase, the advocates assisted the team in understanding the results of the risk questionnaires. For example, most women did not know the type of breast cancer that they had been diagnosed with or even if it was invasive. The advocates confirmed how and why even highly educated women would not necessarily retain this information. Finally, the advocates will have a strong role in the eventual dissemination of the study findings to women.

Conclusions: The investigators have developed a breast cancer risk model that includes an automated measurement of breast density, with the goal of personalizing screening for women. The inclusion of patient advocates throughout all phases of the study improved knowledge and insight of the investigating team. Their role extended beyond community engagement and development of study materials. The advocates became integral members of the study team.
Title: Measurements of advocate participation in and contributions to the Mayo Clinic breast cancer SPORE

Cynthia Chauhan¹, Wayland Eppard¹, Lori Denison¹, Debra Gearhart¹, Lawanna Holmes¹, Ruth Kraft¹, Linda Miller¹, Mary A Sitta¹, Mary L Smith¹, James Ingle¹ and Matthew Goetz¹. ¹Mayo Clinic, Rochester, MN.

Body: [Background] Patient advocates bring a unique, valuable perspective and presence to SPOREs. However, although patient advocates are recommended members of SPORE grants, guidelines are not given on the role of advocates or on measurement of the performance of advocates. [Methods] The Mayo Clinic Breast Cancer SPORE Patient Advocate Advisory Committee has developed a participation measurement tool. This tool will underpin and augment evaluations of the individual advocate contributions by the program PI and the SPORE project leaders. The Advocate Advisory Committee Chair will review the evaluations with the individual advocates. Annually, the advocate committee will review the performance of the group by the standard of the metrics. [Results] Advocates kept a log of their SPORE activities for four months then worked with a statistician to discern patterns of measurable, evaluable behaviors. The determined evaluable areas are training, scientific activity, meeting attendance, communication. Currently, those metrics are being tracked. Advocates developed the metrics together and report activities at the monthly advocate meetings. Currently, activities are simply tracked and categorized. No minimum standards are set. This will be the third step in the development of the metrics. [Conclusions] This approach is the first step in the development of meaningful evaluation of advocate SPORE activities. It quantifies the participation of advocates in the SPORE and provides the basis for developing a qualitative performance evaluation. The SPORE PI and the Committee Chair will use the evaluations to interpret the involvement of advocates in SPORE research and activities and to plan interventions to strengthen the advocate contributions to the SPORE.
Title: ICRP analysis: Obesity research in breast cancer

Kari Wojtanik¹, Rhonda Aizenberg², Susan Higginbotham³ and Lynne Davies⁴. ¹Susan G. Komen, Dallas, TX; ²Pancreatic Action Cancer Network; ³American Institute for Cancer Research and ⁴International Cancer Research Partnership.

Body: The International Cancer Research Partnership (ICRP) is an alliance of governmental and charitable organizations from the USA, Canada, Europe, Australia and Japan, funding regional, national and international cancer research grants and awards. One key activity of the partnership is the ICRP database of information about member’s funded grant projects (N>60,000 grants, from 80 members, totaling $13.6 billion USD). Each project is coded to a Common Scientific Outline (CSO) classification, a classification system of broad areas of cancer research. Obesity has been associated with an increased risk of developing several cancer types, including breast cancer. Worldwide, obesity rates have nearly doubled since 1980 (WHO), and there is significant concern that rising rates of obesity will result in additional obesity-related cancer incidence. Breast cancer is the most common cancer in women worldwide and its incidence has risen in most countries in the last 30 years.¹ In addition, there is convincing research evidence that body fatness is linked to breast cancer incidence (postmenopause).² With this in mind, the ICRP has analyzed obesity-related breast cancer research in its portfolio over three time periods: 2006, 2008 and 2010.

Methods: Using a combination of keyword searches and manual review, a total of over 1040 awards over the period 2006-2010 were found in the ICRP portfolio that were related to obesity and cancer. Of these, 353 awards were considered to be relevant to breast cancer (relevance ≥25%). These were assessed by Common Scientific Outline (CSO) areas.³ Results: The numbers of obesity-relevant awards and research investment were higher for breast cancer than for any other cancer type in the ICRP portfolio from 2006 to 2010. Research was being conducted across all CSO areas, from basic biology, etiology, prevention, early diagnosis/prognosis to treatment and cancer survivorship. Between 2006 and 2010, there was a slight decrease in etiology research (CSO2), and an increase in research into cancer survivorship (CSO6). It is notable that training awards are increasing, indicating that the research organizations contributing data to this analysis consider workforce training to be a priority area.

Conclusion: We were able to use the ICRP database to identify trends in funded grant projects related to obesity research and breast cancer. Despite increased numbers of awards, the overall stasis in research funding over this period, and the decline in investment in etiology is concerning. As breast cancer incidence continues to increase, research efforts to understand the causes of increased incidence are essential. Further research investment in these areas may be required.

Title: onlineDeCISion.org: An interactive web-based clinical decision aid for DCIS treatment

Elissa M Ozanne¹, Natasha K Stout², Katharine Schneider³, Djøra Soeteman⁴, Deborah Schrag², Michael Fordis³ and Rinaa S Punglia². ¹Dartmouth Institute for Health Policy, Hanover, NH; ²Harvard Medical School; ³Baylor College of Medicine, Houston, TX and ⁴Tufts Medical Center.

Body: Purpose: Treatment decisions regarding Ductal Carcinoma in Situ (DCIS) are complex, and patients often have inaccurate and incomplete understanding of the risks and benefits they face. Our objective was to create a web-based decision aid (onlineDeCISion.org) that can be used in clinical practice to guide both clinicians and their patients with these decisions.

Methods: We developed a web-based clinical decision aid to provide tailored information about DCIS treatment choices including an individual patient’s risk of recurrence, likelihood of long-term breast preservation and survival outcomes following up to 6 different treatment strategies for DCIS (lumpectomy, lumpectomy with radiation, lumpectomy with tamoxifen, lumpectomy with radiation and tamoxifen, and mastectomy with or without breast reconstruction). The decision aid is populated by our previously developed simulation model of DCIS outcomes. A theoretical framework and best-practices for web-based decision tools guided the development of the decision aid including semi-structured interviews and usability testing with a diverse group of multidisciplinary clinicians and patient advocates.

Results: The decision aid was designed to include these key features: 1) descriptions of treatment options; 2) ability to input patient health-adjusted age; 3) tailored likelihood of time-specific (10-year and lifetime) recurrence and survival outcomes; and 4) projections of downstream effects of each treatment. The decision aid provides default recurrence risks based on clinical trial data but allows clinicians to customize 10-year DCIS and invasive recurrence risks to retain flexibility to display expected outcomes for individual patients. These estimates can be based on the patient’s actual age, or age adjusted for health status, allowing for a more realistic expectation of the benefits each treatment holds.

Conclusion: Our web-based decision aid displays tailored outcomes following different treatment strategies for DCIS, allowing patients to be better informed about the tradeoffs of treatments available to them and select treatments consonant with their personal preferences, improving the quality of decision making for DCIS. The interactive design features allow users of the decision aid the ability to address uncertainty around risks of recurrence and comorbidity risks and facilitate the use of the decision aid across diverse populations. While the decision aid warrants further evaluation, the results of our study promise to improve decision making in patients with DCIS.
Body: Background
App. 200 new breast cancer patients are treated each year with chemotherapy at the outpatient ward at Roskilde Hospital in the Region of Zealand. The adverse effect of the treatment determines whether the patients are able to receive the planned dose. Studies indicate that the easier access patients have to accurate and relevant information about their disease, the better they manage. Other studies indicate that the better the patients handle the adverse reactions to chemotherapy, the more they comply to treatment as planned. The patients are the best to report the experience of their side effects, so it was an obvious choice to get the patients to self-report adverse effects.

Aim
The primary aim of the study was to create an online portal that could provide patients with better access to relevant guidance and accurate information about self assessed side effects

A secondary aim was
- to provide the patients with relevant information at the right time in order to increase their empowerment to act and comply with the treatment.
- the development of a database based on all the registrations done by the patients for further research and developmental projects.

Methods
We created, as part of a national project, an online portal, where the patients can make real time records of their side effects. The adverse effects were graded according to CTCAE standards. According to the grading the patients get practical online advice on how to act. The portal enabled the patients to get a visual overview of the time-line of their own adverse effects, and a possibility to compare the timelines of adverse effects with other similar patients. The patients were interviewed by telephone as to their experience with the use of the portal

Results
55 pt were included, 35 pt gave feed-back to the portal. Median age 61 år. Average IT kompetence level was 3,9 (out of 5): “experienced user and adequate in surfing on the internet”

Results
28 out of 35 patienter experienced benefit from the advices and instructions given on the portal. It was after the first series of treatment and in connection with newly experienced side effects that the advices were experienced as most valuable. It was appreciated that the portal could give “round the hour” advices. It was appreciated that the advices were practical instructed the patients as to what they could do themselves.

Conclusion
There was a patient demand for an around the clock realtime support to the experienced adverse events.
- It is of great importance that the portal is easy to access and intuitive in use.
- It is essential to find the right balance between secure login and easy access for the patients.
- Mobile access to the portal would bring the help closer to the patients and generate more data for the database.
Decision-making surrounding adjuvant chemotherapy in young women with early stage breast cancer

Shoshana M Rosenberg¹, Karen Sepucha², Kathryn J Ruddy³, Lidia Schapira², Steven Come⁴, Virginia Borges⁵, Evan Morgan¹, Nancy U Lin¹, Shari Gelber¹, Rulla M Tamimì⁶ and Ann H Partridge¹. ¹Dana-Farber Cancer Institute, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Mayo Clinic, Rochester, MN; ⁴Beth Israel Deaconess Medical Center, Boston, MA; ⁵University of Colorado, Aurora, CO and ⁶Brigham and Women's Hospital, Boston, MA.

Background: There is an increasing recognition that many young women with breast cancer will have favorable outcomes without chemotherapy. We sought to characterize decision-making surrounding adjuvant chemotherapy treatment (CT) in this population for whom chemotherapy has historically been a standard of care.

Methods: As part of an ongoing, multi-center, prospective cohort of young women diagnosed with breast cancer at age 40 and younger, we identified 657 women with Stage I-III breast cancer. Participants were asked to complete surveys by mail that included questions about socio-demographics, decision-making, and treatment history within the first year following diagnosis. Tumor characteristics were ascertained via pathology and medical record review. We used Chi-square tests to compare: decisional involvement (patient-driven vs. shared vs. physician-driven), degree of confidence, and feeling informed about the CT decision (the latter two measured on a 0-10 scale, categorized as follows: 0-5=low; moderate=6-8; 9-10=high) between women who did and did not receive CT. To explore clinical appropriateness of the CT decision, we used logistic regression to assess the relationship between tumor characteristics and non-receipt of CT among women with Stage I/II disease.

Results: Among women with Stage I (n=250), II (n=312), and III (n=95), disease, 66%, 95%, and 100%, received CT, respectively. A greater proportion of women who had CT were highly confident with their decision compared with women who did not have CT (80% vs. 60%, p<0.0001); women who did not have CT were more likely to report a low level of feeling informed about the CT decision compared to women who received CT (20% vs. 5%, p<0.0001). Women who did not have CT were also more likely to report the final CT decision as made by their doctor (49% vs. 28%) and less likely to report a shared decision (33% vs. 59%, p<0.0001). Non-receipt of CT in women with Stage I/II disease (n=546) was associated within having node negative disease, T1 (vs. T2 or larger), Her2- negative, and hormone receptor positive tumors.

Conclusion: Although non-receipt of CT would be expected to be viewed favorably by patients and doctors, we found that women who received CT felt more confident and better informed than those who received no CT. Given that women who did not have CT were also less likely to perceive the CT decision as shared, improved communication together with better decisional support may be beneficial, especially for women who do not receive adjuvant chemotherapy.
Title: Characterizing the metastatic breast cancer patient experience around preparing for a treatment decision

Joanne Buzaglo¹, Melissa Miller¹, Anne Morris¹, Allison Harvey¹ and Mitch Golant¹. ¹Cancer Support Community, Philadelphia, PA.

Body: Background: An estimated 155,000 people are living with metastatic breast cancer (MBC) in the US. With new developments in treatment, people are living longer with MBC and are confronted with more complex treatment decisions. Patient-provider communication is typically inadequate and patients are not fully prepared for communicating effectively with their doctor.

Methods: Since March 2013, the Cancer Support Community has registered 909 people living with MBC to the Cancer Experience Registry, an online initiative designed to learn and raise awareness about the psychosocial impact of cancer. 572 registrants responded to questions about their experience with making treatment decisions. This sample was 99% female, 91% Caucasian, and 69% with a college degree and median age 56. Median time since MBC diagnosis was 3 years.

Results: Before making a treatment decision, nearly all (91%) reported receiving information about their cancer type; 76% received information about their treatment choices. Only 41% indicated they received information about clinical trials prior to making a treatment decision. Just over half reported they had quite a bit of knowledge about their treatment options. However, 22% had little or no knowledge about their treatment options. Thirty-eight percent received treatment decision support prior to making a treatment decision; 45% would have liked more support. Twelve percent had little or no involvement in their treatment decision-making process. Nearly one-third (29%) did not feel they had a treatment choice and 28% reported they did not have enough time to make a treatment decision. Those who wrote down a list of questions prior to their first visit to discuss treatment options with their health care provider felt significantly more prepared to discuss their treatment options (p<0.001). About two-thirds of MBC registrants were satisfied with various aspects of the treatment decision-making process: outcome of the treatment(s) received (70%); doctor’s explanation of the benefits of each option (67%); how they arrived at a decision (66%); how much they participated in making the decision (64%); and their doctor’s explanation of the risks and side effects (64%). Sixty-nine percent thought it would be important to get help with gathering information, and 68% with developing a written list of questions before their meetings with cancer specialists; only 47% thought it important to obtain audio-recordings of appointments.

Conclusion: Although over two thirds of these women were satisfied with various aspects of treatment decision making including their communication and interaction with their doctor around the decision, nearly 30% of women thought that they had no choice or felt rushed in making a decision. Those women who prepared a list of questions prior to a consultation with the doctor were significantly more prepared in making an appropriate decision. While a small majority of patients report being knowledgeable about treatment options, a significant proportion report not having enough knowledge or support to fully engage in a treatment decision. Further efforts are needed to address gaps in the delivery of decision support to MBC patients.

**Title:** eHealth in modern breast cancer treatment: New possibilities in communication between patients, doctors and nursing staff

Rachel Wuerstlein¹, Thomas Kirkovits¹, Caroline Drewes¹, Daniel Schiltz¹, Ingo Bauerfeind², Renate Haidinger³, Kerstin Paradies⁴, Ursula Goldmann-Posch⁵, Timo Schinkoethe¹ and Nadia Harbeck¹. ¹Brustzentrum am Klinikum der Universitaet Muenchen, CCC of LMU, Munich, Bavaria, Germany; ²Gynaekologie und Frauenheilkunde am Klinikum Landshut, Landshut, Bavaria, Germany; ³Brustkrebs Deutschland e.V., Hohenbrunn/Munich, Bavaria, Germany; ⁴KOK – Konferenz onkologischer Kranken- und Kinderkrankenpflege, Hamburg, Germany and ⁵Mamazone – Frauen und Forschung gegen Brustkrebs e.V., Augsburg, Bavaria, Germany.

**Body:**

**Introduction:**
Lack of compliance and adherence in oral and s.c. treatment of breast cancer (BC) are huge problems leading to significant impacts in morbidity and mortality. During long term treatment, constant patient contact can't be secured and possible side effects not be treated adequately. Where conventional mailing systems failed, as reported in the PACT program, eHealth could be a possible solution to increase adherence among patients and to ameliorate the communication between patients, oncologist and nurses.

The objective of this study is to investigate the actual internet usage habits and property of new media among BC patients, their oncologists and the nursing staff to find new possible ways to improve compliance and adherence in long term treatment.

**Methods:**
By using 3 different questionnaires (33 items), the actual usage of internet and modern media among BC patients and their healthcare professionals (oncologists and nursing staff) is surveyed. Also, the equipment of media (computer, smartphone, etc.) in private as well as in business use is investigated. Huge care and attention is given to possible future eHealth systems for additional patient support. The collected data also includes age, sex, workplace and, in case of medical professionals, their emphasis.

Patients completed the questionnaire at two patient conventions and before consultations, oncologists and nurses were asked to answer the questionnaire at several local BC meetings.

**Results:**
631 patients, 120 oncologists and 96 nurses completed the questionnaire in 2013.

The internet usage in general and for health related issues is very high among all three subgroups (patients: 93% and 77%, respectively; oncologists: 100% and 98%; nurses: 92% and 93%). Among patients, even above age 60, 51% report to use the internet every day. Taking a look at participant's equipment of new media, the property of a personal computer is very high (78%; 99%; 95%).

Medical professionals as well as the majority of patients can imagine getting additional support during long term therapy using eHealth technologies (e.g. for monitoring of and interventions concerning side effects) (see table).

**Discussion:**
This survey, which is the first BC specific study representing internet usage habits among BC patients and their medical professionals, shows high acceptance of new interactive ways of communication between patients, doctors and nurses who are all taking part in treatment of BC. Introducing eHealth may help increase compliance and improve and individualize the doctor-patient-relationship which will possibly lead to decreased mortality and higher patient and staff satisfaction.

Title: Group visits to provide gynecologic care for women affected by breast cancer

Sally R Greenwald¹, Sarah Watson¹, Tami S Rowen¹ and Mindy Goldman¹. ¹University of California, San Francisco, CA.

Body: Background
Advancements in treatment have resulted in a growing number of women now living with or affected by breast cancer. This patient population has complex and unique gynecologic needs. Two thirds of breast cancers are hormone positive and these patients will often be given Tamoxifen or aromatase inhibitors which have specific gynecologic effects. Additionally, oophorectomy may be done as part of breast cancer treatment. Chemotherapy may induce menopause with the need for safe and effective treatments for menopausal symptoms. Gynecologists have a very important role in providing care to women affected by breast cancer. Group visits are increasingly used to provide education and care in the setting of chronic disease, including breast cancer. There is limited data regarding the use of this type of healthcare delivery in providing gynecologic focused care to this complex and growing patient population.

Methods
This is a cross-sectional study measuring patient expectations and satisfaction with the practice of group visits as a model for providing gynecological health information to women affected by breast cancer. From July 2010 through February 2014 we surveyed women who participated in a two hour new patient visit that involved a one hour information session followed by an approximately 30 minute individual exam with a gynecologist. The goals were to measure the role of a small group format and an individual’s sense of satisfaction with their gynecology clinic experience. Demographic data was collected to determine if there were any correlations with satisfaction and women’s age, stage of disease, hormone receptor and menopausal status.

Results
A total of 104 women participated during the study period. Over 80% of participants in group visits felt that their expectations were met during the visit. Eighty five percent felt they had a better knowledge of treatments for gynecologic side effects from cancer treatments. When assessing disease and demographic factors that might be associated with satisfaction, we found that women with hormone receptor positive breast cancer and those with treatment induced menopause were more likely to prefer group visits than women with hormone receptor negative breast cancer or natural menopause. Women with stage 3-4 disease preferred the group education visit experience more than women with stage 1-2 disease.

Conclusion
There is a need to provide comprehensive gynecologic care and education to the expanding population of women impacted by breast cancer. Our data suggests that group visits are an effective and well-received strategy for providing gynecologic care to this niche patient practice. Incorporating a group visit model into a practice is a cost-effective educational modality to providing sources of information and support. Based on our observed differences in satisfaction and preference for group visits by stage of disease, menopause status and hormone receptivity, we recommend investigations grouping similar patients to further improve unique patient education and satisfaction.
Title: Patient experience of the introduction of an enhanced recovery programme for breast cancer surgery

Alistair RM Macey¹, Jayne I McGIvern¹, Juliette Murray¹ and Alison K Lannigan¹. ¹Wishaw General Hospital, Wishaw, Lanarkshire, United Kingdom.

Body: Introduction
The introduction of an enhanced recovery programme for breast cancer surgery in our institution has provided an opportunity to redesign the service and the way in which patients receive pre-operative information. It has been a challenge to provide the same amount of information and support for patients with a shorter period of inpatient stay. The enhanced recovery programme has been shown to reduce inpatient stay by 50% with no increase in complications¹. Almost all patients having breast conservation and sentinel node biopsy are day cases and those who have a drain in following mastectomy or axillary node clearance typically go home the day following surgery.

Aim
To audit patient experience, outcome and satisfaction following the introduction of an enhanced recovery programme.

Methods
An enhanced recovery programme was first introduced in our institution in Sep 2012. Between December 2012 and December 2013 80 patients having breast cancer surgery in Wishaw were sent a detailed questionnaire asking them about all aspects of their treatment. Two patients were excluded from the questionnaire one because of learning difficulties and the other because of acute psychiatric illness. There was a 89% response rate with 71 responses having been received to date. All patients reported that they were given enough information at the time of their diagnosis. 97% were supported at this time by a breast care nurse and found this helpful. 84% were given a written record of their proposed treatment and 94% of patients had a further pre op consultation with a breast care nurse to discuss treatment which was felt to be helpful. At this appointment half of patients were able to meet a physiotherapist and go over post-operative arm exercises. 86% of patients felt that the length of stay was just right and 8% of patients felt it was not long enough. 70% of a patients were discharged in the afternoon, between 12.00 and 17.00, 9% in the morning and 21% after 17,00. A third of patients had a drain in situ at the time of discharge and 90% reported no concerns at all about going home with a drain. Of the 40% of patients that did need to get in touch with a post op question prior to clinic three quarters contacted their breast care nurse and all reported being satisfied with the management of their query or problem. Overall 79% of patients reported being very satisfied and a further 14% satisfied with the communication and management of their diagnosis and surgery.

Conclusion
An enhanced recovery programme can be introduced to reduce inpatient stay while still offering enough support and information for breast cancer patients around the time of surgery.

Title: Understanding potential gaps in treatment discussions between caregivers/patients with metastatic breast cancer and oncologists

Musa Mayer¹, Helen L Coons², Stephen Jones³ and Deana Percassi⁴. ¹AdvancedBC.org, New York, NY; ²Women's Mental Health Associates, Denver, CO; ³Molecular Health, The Woodlands, TX and ⁴Nielsen Consumer Insights (formerly Harris Interactive, Inc.), Rochester, NY.

Body: About 5% of newly diagnosed cases of breast cancer in the US involve cancer that has metastasized to distant parts of the body, and about 20%-30% of patients diagnosed with early-stage breast cancer later experience a distant metastasis. The 2013 Global Count Us, Know Us, Join Us survey found that 53% of US women with metastatic breast cancer (MBC) surveyed wished they had more time to discuss their needs during healthcare visits, and 60% believed their cancer treatment options are limited.

To better understand unmet patient emotional, informational, and care needs and potential communication gaps in discourse with physicians, the Make Your Dialogue Count survey was developed for (1) women ≥21 years of age with MBC; (2) caregivers of women with MBC who are ≥21 years of age; or (3) licensed US medical oncologists who treat ≥5 women with MBC per month.

Surveys were conducted online, by paper, and by telephone in the US from June through August 2014. Respondents to one survey were not necessarily related to or associated with respondents to another survey. Patient and caregiver data were unweighted. Oncologist data were weighted by geographic region and years in practice by sex to align with actual proportions in the population.

The survey was completed by 359 patients, 234 caregivers, and 252 oncologists. Patients/caregivers were mainly white (81%/73%) or hispanic (8%/18%). Most oncologists practiced general oncology (74%), for a mean of 18 years.

Patients/caregivers lacked some basic disease knowledge: 20%/29% did not know the HER2 status, 16%/20% did not know the hormone receptor status, and 28%/32% reported being told by oncologists that MBC was possibly curable. At initial diagnosis of MBC, all groups felt it was important to discuss expectations for treatment efficacy and side effects and long-term plans and goals, but patients/caregivers reported that these topics were not discussed often enough. When patients were asked what emotions they felt, and oncologists what emotions they observed in their patients at the time of initial diagnosis of MBC, surveyed patients were less scared, anxious, distressed, and worried, but also less committed, determined, hopeful, and confident than oncologists observed their patients to be. Most (71%) patients had ≥1 treatment change (median of 3 changes among those with treatment changes). Patients at the time of treatment change were less scared and distressed and more hopeful than they had been at the time of initial diagnosis of MBC, suggesting adaptation to and/or acceptance of disease status over time. Patients said they were committed to proactively managing side effects (96%) and wanted more information on side effect prevention and minimization (73%), yet only 57% openly discussed side effects with their oncologists. Still, 46% of patients wished their healthcare teams did more to help them manage side effects.

The Make Your Dialogue Count survey identified gaps in the discourse between patients/caregivers and oncologists that directly affect disease management. Closing these gaps and understanding the needs of patients throughout their journey are necessary to establish effective patient/caregiver-oncologist relationships and provide patients with the care they need.
Title: Treatment of metastatic breast cancer patients by community health practitioners: Practice pattern and competence assessments

Sara R Fagerlie¹, Alison Heintz¹ and Maureen Haas¹. ¹Educational Concepts Group, LLC, Atlanta, GA.

Background: The complexity of current treatment and management for patients with metastatic breast cancer continues to rise. The volume and pace of scientific advances make it challenging for the community practitioner to stay abreast of optimal patient care. Education is key in disseminating critical information to practitioners and allows professional reflection of appropriate therapeutic decision making and peer discussion. Understanding the base knowledge, competence, and current practice patterns of the community practitioner is critical to identification community needs and implementation of education that impacts patient care.

Methods: During 2013 and 2014, educational outcomes assessments were gathered during 2 education programs consisting of 47 live independent continuing medical education (CME) activities held within community practices across the USA. Participants were asked a series of case-based questions via an audience response system to assess baseline knowledge, competence, and identify practice patterns. Assessments were repeated following the 1-hour CME certified activity. Long-term assessment was conducted electronically 6-weeks following the educational initiative.

Results: The programs educated 958 practitioners, including 515 physicians. Practice patterns for frontline treatment varied at baseline. Education resulted in treatment more highly aligned with practice guidelines and recent advances. At baseline 75% of practitioners and 30% of the physician target audience were unable to identify appropriate next steps in a borderline HER2+ patient. The education reduced the gap by 25%. 6-weeks following the activity 100% of the assessed physician target audience agreed or strongly agreed that the education influenced their interpretation of HER2 testing. Practice gaps in practitioners ability to identify, recall, and interpret practice changing clinical trials were also identified. Newness of treatment data, lack of reimbursement, and treatment side effects were the most common barriers identified in applying the education into clinical practice.

Conclusions: The results highlight the diversity of current clinical practice in the community practice setting for patients with metastatic breast cancer and the positive impact of focused education. Knowledge and competence practice gaps were identified to pinpoint specific areas of benefit for the community practice setting in the treatment of patients with metastatic breast cancer.
Title: Managing breast and ovarian cancer risk: A novel approach to teaching residents comprehensive risk reduction and management strategies

Deborah S Lindner1. 1Northwestern University Feinberg School of Medicine, Chicago, IL.

Body: Introduction: Awareness about genetic predisposition to breast and ovarian cancer and access to genetic testing has increased dramatically over the last decade, particularly with the increase in direct to consumer marketing of genetic testing. While professional organizations have published bulletins addressing this topic, a working knowledge of how to identify and manage high risk patients is lacking among many physicians. The goal of this pilot study was to assess knowledge deficits in breast and ovarian cancer risk assessment and management among primary care residents and to determine whether a novel approach to teaching this subject will help bridge the perceived knowledge gap.

Methods: A novel case based learning module was developed by a multidisciplinary team of Breast Surgeons, Gynecologic Oncologists, Obstetrician/Gynecologists, Psychologists and Genetic Counselors as a practical approach to assessing risk level based on personal and family history and applying standard recommendations for screening and risk reduction. This approach is unique, as lectures in an academic setting often focus on management of high risk patients, but not on risk stratification and risk reduction in all comers. Surveys were completed by residents after the workshop to assess perceived knowledge before and after the presentation.

Results: 106 residents from Internal Medicine, Obstetrics and Gynecology and Family Medicine residency programs were surveyed after participating in the lecture and case based learning module. 87 (82%) responded that the information presented was new to them. 101 (95%) responded that the training increased their knowledge about the options available to young women for risk reduction and early detection of breast and ovarian cancer. 105 (99%) responded that after attending the training, they understood how to identify patients that are at an increased risk for developing breast and ovarian cancer and should be referred for genetic counseling and testing. 100 (94%) indicated they would incorporate material in the training into their everyday practice.

Discussion: Resident surveys confirmed there is a knowledge gap among trainees in breast and ovarian cancer risk assessment and management. While professional organizations have created guidelines for patient management, most trainees are either unaware of recommendations, or feel the information is not being presented in a way that allows them to use it practically in patient management. The novel educational workshop presented here increased perceived knowledge among residents, allowed them to correctly identify high risk patients, and increased their working knowledge of risk reduction strategies among high and low risk patients. Recent studies have demonstrated poor coordination of care and lack of followup for the majority of high risk patients who do not opt for risk reducing surgery within the first few months after diagnosis of a gene mutation. The need for more comprehensive education among emerging medical professionals in this area is clear. Using a practical, risk stratification approach to identify and manage high risk patients is successful in bridging the knowledge gap among residents in primary care specialties.
Title: Multidisciplinary breast cancer care registry and quality control system in the Netherlands: The NABON breast cancer audit

Vivianne C Tjan-Heijnen¹, Annelotte C van Bommel², Margriet van der Heiden-van der Loo³, Pieter Westenend⁴, Bart de Vries¹, Carolien H Smorenburg⁵, Agnes Jager⁶, Marc B Lobbes¹, Ruud M Pijnappel⁷, John H Maduro⁸, Henk Struikmans⁹, Marc A Mureau⁶, Marga Schrieks¹⁰, Carol Richel¹⁰, Maike Schepens¹¹, Thijs van Dalen¹², Michel W Wouters⁵, Marie-Jeanne T Vrancken Peeters⁵, Emiel J Rutgers⁵ and Sabine Siesling³. ¹Maastricht University Medical Centre, Maastricht, Netherlands; ²Leiden University Medical Center, Leiden, Netherlands; ³Comprehensive Cancer Centre Netherlands, Utrecht, Netherlands; ⁴Albert Schweitzer Hospital, Dordrecht, Netherlands; ⁵Netherlands Cancer Institute, Amsterdam, Noord-Holland, Netherlands; ⁶Erasmus Medical Centre Cancer Institute UMC, Rotterdam, Netherlands; ⁷University Medical Centre, Utrecht, Netherlands; ⁸Medical Centre Haaglanden, Den Haag, Netherlands; ⁹Breast Cancer Patient Organisation, Netherlands; ¹⁰Health Insurer Netherlands, Netherlands and ¹¹Diakonessenhuis, Utrecht, Netherlands.

Body: Background
Previous quality assessments in oncology focused on surgical issues such as number of annual operations per hospital. However, high-quality of care depends on an excellent interplay between all disciplines involved in cancer care. The NABON (National Breast Cancer Organisation of the Netherlands) has, therefore, developed a multidisciplinary set of 30 quality indicators to check and improve breast cancer care. Health insurers have recently decided to use this information for purchasing.

Methods
The NABON Breast Cancer Audit (NBCA) started in 2011. Data on all newly diagnosed patients with invasive breast cancer in the Netherlands are collected by the Netherlands Cancer Registry (n=61 hospitals) or by the physicians themselves (n=31 hospitals). Data capture is facilitated using a web-based portal and feedback to participating hospitals on their own data is being done every week. Since 2012 all Dutch hospitals participate. A set of quality indicators on process and outcome was selected following established clinical guidelines and is being supervised by a multidisciplinary steering committee.

Results
Data of all 41,958 breast cancer patients treated between 2011 and 2013 were collected. In 2013, 94% of patients were discussed in the multidisciplinary team prior to first treatment and 98% after surgery. BI-RADS score was used in 98% of radiological reports. After neo-adjuvant chemotherapy, 7.6% of patients had positive specimen margins following first breast conserving surgery compared to 5.0% and 20% of patients following primary breast conserving surgery for invasive cancer and ductal carcinoma in situ, respectively. Eighteen percent and 36% of patients underwent immediate breast reconstruction after mastectomy for invasive cancer and ductal carcinoma in situ, respectively. Pathological analysis showed 12% of patients had HER2 positive and 85% had ER positive disease. Neo-adjuvant or adjuvant systemic therapy was given to 63% of patients and neo-adjuvant or adjuvant chemotherapy to 39% of patients. Time between diagnosis and first treatment was generally short: 49% to 85% underwent primary surgery with and without immediate reconstruction, respectively, and 76% underwent neo-adjuvant chemotherapy within 5 weeks from first biopsy. At the conference we will show that variation between hospitals was not related to annual surgical volume per hospital.

Conclusion
The NBCA is a unique national system to provide and confirm quality assessment in breast cancer and to drive improvements in quality of multidisciplinary breast cancer care. Present results show an overall high quality of care in the Netherlands and provide insight in items of improvement.
Title: Education and information preferences for women with triple-negative breast cancer: Should personal or medical demographic variables impact program tailoring?

Kathleen D Swiger1, Jocelyn A Sendecki3, Janine E Guglielmino2, Hope S Rugo, Carey K Anders4, Susan M Domchek5, Arin Ahlum Hanson2, Hayley Dinerman6 and Catherine Creme Henry2. 1Consultant, Greensboro, NC; 2Living Beyond Breast Cancer, Haverford, PA; 3Thomas Jefferson University, Philadelphia, PA; 4University of North Carolina, Chapel Hill, NC; 5University of Pennsylvania, Philadelphia, PA and 6Triple Negative Breast Cancer Foundation, Norwood, NJ.

Body: Purpose: To determine interest in tailored breast cancer education and information among women diagnosed with breast cancer based on personal and medical demographics, including subtype of breast cancer, cancer stage, age, living situation (single, married, children, student, retired), race/ethnicity, or sexual orientation.

Respondents and Methods: An 80-question online survey was designed to identify education, information, and support needs among women diagnosed with breast cancer after 2006. Respondents self-identified their breast cancer subtype and selected up to 3 options from a list of preferences about ways in which education and information needs should be tailored. Options were "breast cancer type," "age," "stage," "living situation," "race/ethnicity," "sexual orientation," "no preference," and "other." The responses of 656 women diagnosed with triple-negative breast cancer (TNBC) (25.1%) were compared to those of 1,954 women with other subtypes of breast cancer (74.9%). Logistic regression was used to assess differences in tailoring preferences between TNBC and non-TNBC women.

Results: Compared to non-TNBC women, TNBC women had a significantly stronger preference for information tailored to breast cancer subtype (71% vs. 49%, p<0.001) and race/ethnicity (5% vs. 2%, p=0.002) and significantly lesser preference for tailoring based on cancer stage (43% vs. 47%, p=0.004) and living situation (15% vs. 25%, p<0.001). The difference in preference for racial/ethnic tailoring between TNBC and non-TNBC participants may be due to the overall low proportion of non-white respondents to the survey (18.4%) and the higher proportion of non-whites in the TNBC group (18% vs. 11%, p <0.001). There was a significantly different pattern of preference by age group between TNBC and non-TNBC women. TNBC women under 40 had a stronger preference for tailoring to their age group than younger non-TNBC women (age <30, 89% vs. 77%, age 30-39, 74% vs. 62% p=0.02). Across women of all breast cancer subtypes, cancer stage played a role in tailoring preference. Women with higher stage (stage >=2) breast cancer had a stronger preference for tailoring materials based on cancer stage (p<0.001); this pattern did not differ by TNBC status.

Conclusion: Education and information tailoring preferences show marked differences by breast cancer subtype. Women with TNBC strongly prefer education and information be tailored to their breast cancer subtype and their race/ethnicity, but are less interested in cancer stage or living situation-specific tailoring. Additionally, younger age influenced preferences in women with TNBC. Across all women, advancing cancer stage influenced preference toward stage-tailored materials. Healthcare providers, cancer centers, and breast cancer organizations should consider developing education and information tailored to the needs of TNBC patients and survivors.
Title: Improving completeness of client-level data collection in the Avon Breast Health Outreach Program through electronic tablet technology

Lindsay Senter¹, Marvin R Aliaga¹, Kelly M Opdyke¹, Kathryn Gates-Ferris¹ and Marc Hurlbert². ¹Cicatelli Associates Inc (CAI), New York, NY and ²Avon Foundation for Women, New York, NY.

Body: Background: The Avon Breast Health Outreach Program (BHOP) supports community-based organizations to provide breast cancer education and outreach, and navigate low income and uninsured women to breast cancer screening and treatment. BHOP organizations collect demographic and health information on clients through a standardized interview using the Clinical Intake Form (CIF). Research demonstrates that transitioning away from paper completion to audio-computer assisted self-interview allows for increased rates of survey completion. Given the advancement of tablet technology, there is significant opportunity for organizations to adopt electronic data collection of clinical information to improve data quality.

Objective: This presentation compares rates of CIF completion collected among a low income, diverse client population via two modalities; self-administered paper-based interviews (SAPI) versus electronic collection using iPads.

Methods: The CIF is organized into three sections: demographics [12 items], breast health [9 items], and access/use of health services [5 items]. In 2013, 26 BHOP grantees adopted and utilized iPads to administer the CIF with the iSurvey application, after receiving training and technical assistance on tablet usage. Data were restricted to women >=18 years, who self-administered the CIF, English-only, collected between March and December 2013, and among only those grantees who employed both modalities. The BHOP dataset was analyzed to compare CIF completeness across the two modalities. ‘Completeness’ is defined as having a response to every question in the CIF; ‘missing’ is defined as any question that was not responded to or was left blank. Percent of completeness and mean number of missing responses in the CIF overall and by section were analyzed by modality. Odds Ratios (OR) on completeness by modality were also calculated controlling for race, income, education, place of birth and residence.

Results: There were 8,004 CIFs analyzed; 2,144 via iPad (27%) and 5,860 via SAPI (73%). Among the iPad mode, 84% of the CIFs had complete data, compared to 47% in the SAPI. The mean number of missing values across the entire CIF was 0.2 via iPad, compared to 1.3 with the SAPI. SAPI variables had ten or more times as much missing data as the iPad variables (e.g., "self-reported breast symptoms" item had 7% missing data in SAPI vs. 1% in iPad). Adjusting for key demographic characteristics, clients were seven times more likely to complete the entire CIF via the iPad as compared to the SAPI [Overall OR= 7.3(6.0-9.0)].

Conclusions: Given the significantly higher rates of CIF completion using iPads, there are important implications for health care organizations to adopt and utilize electronic collection of their health interview data. Future research should study iPads ability to handle high patient volume in less time and with more accuracy compared to SAPI.

Discussion: Tablets are a relatively inexpensive option for organizations dedicated to assuring complete data collection. While administrative barriers arise with new technology, the significantly positive aspects of tablet data collection of increased quality and completeness overshadow such burdens.
Title: Perceptions about cancer clinical trials among metastatic breast cancer patients: Findings from a patient powered registry

Anne Morris¹, Melissa Miller¹, Allison Harvey¹, Mitch Golant¹ and Joanne Buzaglo¹. ¹Cancer Support Community, Philadelphia, PA.

Body: Background: An estimated 155,000 people are living with metastatic breast cancer (MBC) in the US. With new developments in treatment, people are living longer with MBC. Advances in treatment are handicapped by patients’ limited (3-5%) participation in cancer clinical trials (CCTs). While much effort has been placed on better training physicians and health care providers in talking to their patients about the appropriateness of such participation, barriers remain.

Methods: Since March 2013, the Cancer Support Community has registered 909 people living with MBC to the Cancer Experience Registry, an online initiative designed to learn and raise awareness about the psychosocial impact of cancer. 557 registrants responded to questions about their beliefs, attitudes and experience with CCTs. This sample was 99% female, 91% Caucasian, and 69% with a college degree and median age 56. Median time since MBC diagnosis was 3 years.

Results: Only half of registrants reported that a member of their health care team spoke to them about participating in CCTs. Nearly one-quarter (23%) report that they took part in a CCT. 48% considered a CCT as a treatment option for their MBC and 34% did not know if a CCT was available to them. 67% are uncomfortable with being randomly assigned to a treatment. 18% do not trust the medical establishment and fear they will be used as a “guinea pig” for research. 63% fear receiving a placebo in a CCT; however, only 6% report that they don’t understand what clinical trials are. The table below shows differences in beliefs between those who report participating in a CCT and those who have not participated in one.

<table>

</tbody>
</table>

Conclusion: This population of MBC patients reports a range of experiences and often conflicting beliefs about CCTs. While this survey is limited to self-report data, there is persistent suspicion among these women about participating in CCTs. Although these women report that they understand what a CCT is, they fear receiving a placebo and being randomized to different treatment arms without at least the standard of care. These misconceptions persist even among people who have participated in a CCT.
These findings highlight the need for treatment decision counseling that educates patients about all their treatment options including CCTs and for training of health care providers to better inform patients about CCTs.
Title: The financial costs of metastatic breast cancer and the decisions patients make to cope with costs: Findings from the Cancer Experience Registry

Joanne Buzaglo¹, Anne Morris¹, Melissa Miller¹, Allison Harvey¹ and Mitch Golant¹. ¹Cancer Support Community, Philadelphia, PA.

Body: Background: An estimated 155,000 people are living with metastatic breast cancer (MBC) in the US. With new developments in treatment, people are living longer with MBC and have to manage greater financial burden related to care, including copays and out of pocket costs.

Methods: Since March 2013, the Cancer Support Community has registered 909 people living with MBC to the Cancer Experience Registry, an online initiative designed to raise awareness about the psychosocial impact of cancer. 496 registrants responded to questions about the financial cost of MBC. This sample was 99% female, 91% Caucasian, and 69% with a college degree and median age 56. Median time since MBC diagnosis was 3 years.

Results: 38% of registrants report being seriously or very seriously concerned about health insurance or money worries and 46% reported currently experiencing intrusive ideation about the financial cost of care. Registrants reported experiencing a significant burden from MBC related expenses, as shown in the table below.

<table>

</tr>
</tbody>
</table>

Because of these expenses, registrants have: foregone vacations, celebrations, and social events (53%); sold property (12%); refinanced their house (13%); filed for bankruptcy (5%); downsized their living accommodations (16%); liquidated their assets (19%); depleted their savings (40%); borrowed against or used money from a retirement plan (27%); cut their grocery expenses (42%); applied for or used public assistance (14%); chosen a treatment that is not as effective but costs less (9%); asked their doctor if there was a less expensive treatment (19%); tried to negotiate payments with credit companies (24%); negotiated with service providers to reduce costs (22%); used pharmaceutical assistance programs (26%); accepted money from friends or family (39%); and cashed in a life insurance policy early (8%), among others. In order to reduce the cost of treating MBC, registrants often or always postpone seeking psychological counseling or support (20%) and delay follow up on recommendations for complementary treatment such as physical or occupational therapy and nutrition counseling (13%).

Conclusion: MBC places a significant financial burden on patients, which can result in patients taking measures that can significantly impact their quality of life. Future implications for research include the development and evaluation of interventions designed to enhance doctor-patient communication and support (e.g., financial counseling) to ensure that the financial cost of MBC does not negatively impact the patient’s quality of life, course of cancer care, and health outcomes.
Introduction:
Breast cancer survivors benefit from supportive, professionally facilitated group discussions to assist their individual recovery from treatment and place their cancer in a life perspective. We have developed a multi-session group discussion to aid survivors in this path of recovery.

Materials and Methods:
The Pink Ribbon Survivors Network (www.PinkRibbonSurvivorsNetwork.org) has developed an online library for breast cancer survivors titled, "The Curriculum for Recovery." This library contains professionally vetted online articles in 19 categories related to survivorship issues facing breast cancer survivors. The library houses over 400 articles, in total. We have developed a 5 session program of discussion for breast cancer survivors integrating this library resource as a basis for discussion material. The 5 sessions are titled: 1.) Physical Recovery and New Adjustments, 2.) Nurturing Yourself: The Importance of Self-Care 3.) Fostering Positive Relationships, 4.) Understanding your Emotions: Doubt and Hope in Survivorship, and 5.) Prioritizing, Leaving Your Legacy, Moving Forward.

Each session draws from specific categories of the Curriculum for Recovery Library. Participants are asked to read specific articles from the online library in preparation for group discussion. The 5 sessions lead the participants from the issue of immediate physical recovery to gaining a philosophic life perspective on the impact of breast cancer in their lives.

Results:
Website usage: Since its inception in July, 2012, the website's resources have been accessed from 2300 cities in 128 countries. Its libraries have been viewed 9,000 times, tallying over 30,000 page views. The Survivors' online library hosts information in 19 different categories. Separate online libraries specialize in clinical literature for cancer care professionals and primary care professionals.

During registration for this group, participants will be asked about coping issues, and their goals in this group participation. Feedback after each session will be obtained. We intend to develop a manual for professional facilitators to use in order to be able to facilitate similar groups in their center. This manual will be available online within our website's libraries.

Discussion:
Studies have shown that breast cancer survivors benefit from group participation for support, education and discussion during their breast cancer recovery. We have developed a multi-session group discussion program that can be replicated free of charge at any location, utilizing the online resource noted here, along with the comprehensive facilitator's guidelines. This program is designed to bring survivors from initial issues of early recovery to gaining a broad perspective of how breast cancer has affected the individual's life and her future. This program is well represented in a brief live presentation at the San Antonio Breast Cancer Symposium that will be illustrative of its value to breast cancer survivors, and the ease of replication at other locations.

Title: Psychological status of early breast cancer (EBC) patients (pts) after surgery and before the starting of aromatase Inhibitors (AIs). Results of a single-institution, prospective study

Marina E Cazzaniga¹, Annalisa Valentini¹, Francesca Gallina¹, Francesca Riva¹, Alessandra Crippa¹, Marco Tagliabue¹, Federica Cicchiello¹, Diego Cortinovis¹ and Paolo Bidoli¹. ¹AO S Gerardo, Monza, MB, Italy.

Body: BACKGROUND
AIs are the milestone adjuvant treatment for postmenopausal early HR+ BC pts. Non-steroidal AIs induce a significant oestrogen deprivation, responsible in approximately 40% of the pts for muscle-skeletal adverse events (MSKs) and for discontinuation in 25%. The present study aims to evaluate the impact of the diagnosis communication and of the need for AI therapy on the future development of MSKs events in a prospective cohort of EBC pts.

PATIENTS AND METHODS
The analysis of patients’ psychological attitude was conducted by using 3 different tests: SCL 90-r for psychological symptoms, SF-36 for the self-perception of the health status and COPE-NVI for evaluation of coping. After a full explanation of the AIs potential adverse events by the oncologist, the questionnaires were self-administered with the support of a dedicated psychologist at the moment of the first visit (T0). For the future correlation between baseline psychological attitude and the development of AI-related events, the presence and the intensity of pain were measured by NRS 11-points scale and by Tender Points (TPs) evaluation. Pearson correlation analysis was used to calculate correlations between Pain Scale, Physical Synthetic Index of SF-36 and NRS/TRPs scores. Wilcoxon’s Test was used to compare baseline scores with subsequent ones.

RESULTS
From October 2012 to April 2013, 70 EBC pts entered the study. Exclusion criteria included severe osteoporosis or other co morbidities that contraindicate therapy with AIs and documented diagnosis of psychosis or cognitive deterioration. Median age was 64.8 years (43-88). The vast majority of the pts (584.3%) presented stage IA-IIA disease. Fifteen pts aged less than 55 years were menopausal, 13 have previously received chemotherapy as part of the planned adjuvant programme. Thirty-four pts (48.6%) had a baseline NRS>0 and 18 NRS>5; 26 pts presented at least 1 positive TP. Regarding the SCL 90-r analysis, all the pts have reported standardized scores within the normal ranges for somatization, anxiety and phobic anxiety. The analysis of SF-36 questionnaires indicated that pts showed a significant lower score in comparison to the reference population in the ISF Index (44.17 vs 48.7) and in the Physical Health Scale (47.5 vs 74.13). These differences could suggest a greater difficulty to do daily activities and a worse global index of self physical perception.
At baseline, there was a statistically significant correlation between Physical Pain Scale of SF-36 and NRS Pain score (p=0.001) and between Physical Synthetic Index of SF-36 and NRS Pain Score (p<0.001). No differences have been observed in the COPE NVI questionnaires between the studied population and the reference one.

CONCLUSION
Early BC pts who are candidate for endocrine adjuvant therapy with AIs often present an impairment in terms of physical activity (daily and working) and perception of physical pain. The analysis of these parameters along the 1st year of AI therapy and their correlation with MSK adverse events onset is ongoing.
**Title:** Sources of information and influence on decisions regarding contralateral prophylactic mastectomy: A prospective study

Swati A Kulkarni¹, Martha Van Haitsma¹, Kristen Wroblewski¹, Sarah Rabbit² and Kathy Yao². ¹University of Chicago, Chicago, IL and ²NorthShore University HealthSystem, Evanston, IL.

**Body:** Background: The number of women with a newly diagnosed ipsilateral breast cancer requesting contralateral prophylactic mastectomy (CPM) has increased significantly in recent years. Little is known about the sources of information women utilize as part of their decision making process regarding the choice of CPM.

**Methods:** A 55-item survey validated with breast cancer survivors was administered to 136 women with newly diagnosed breast cancer before they underwent surgical therapy at two institutions. Women were asked about the influence of medical personnel, individuals outside of medicine, websites and social media on their decision to keep or remove their healthy breast.

**Results:** The median age was 58 years (range 30-85); 69.2% were White, 26.7% were African American and 4.2% were Asian; Thirty-eight (28.6%) of patients had a first-degree relative with breast cancer. Seventy-five (58.6%) had a lumpectomy, 41 (32%) had a unilateral mastectomy and 12 (9.4%) had a CPM. About 80% of women felt the information they were given about breast cancer treatment was consistent. Fifty-five patients (41.7%) sought out extra information beyond what the doctor gave them. Sources of information that had strong or some influence were websites and books recommended by their doctor (44%), websites, followed books not recommended by their doctor (30.4%), and magazines (15.4%). Only 6.7% said that social media had some or strong influence on their decision making; 61.7% stated that they completely or mostly relied on their doctor’s advice to make treatment decisions and ranked their doctor’s spoken advice (74.3%) as the most important source of information in making their decision to keep or remove their healthy breast. However, Eighty-two women (62.6%) stated that information provided by staff did not include any information about removing the healthy breast. Forty-one (36%) stated that no one discussed contralateral breast cancer risk and 67 women (59%) stated that no one talked with them about the possibility that cancer could turn up somewhere else even if both breasts were removed. Of medical personnel, women stated that their surgeon (81%) had the most influence on their decision, followed by their oncologist (59.1%) and reconstructive surgeon (29.8%). When asked who influenced their decision outside of medicine, 58.7% of women stated that other breast cancer survivors influenced them. Reconstructive surgeons and the spouse/partner had more influence on those <50 years old compared to >50 years old (p=0.03). Oncologists (p=0.004), nurses and trained counselors (p=0.06-0.08), had more of an influence for African Americans compared to Whites.

**Conclusions:** Many women with newly diagnosed breast cancer do not receive information about CPM, contralateral breast cancer risk or how CPM affects recurrence from their physician. However, women still highly value their doctor’s advice and information provided by their doctor but one third of women state that websites identified on their own strongly influence their decision making for CPM. These findings highlight an opportunity for physicians to educate women about the utility of CPM as part of their surgical treatment.
Purpose/Objectives: RT is associated with acute treatment-related complications that can lead to poor quality of life (QOL) and fatigue. Exercise has been shown in other cancer treatment settings to improve negative outcomes. We conducted a prospective pilot study to explore the association between exercise, patient-reported outcomes (PROs), and radiation therapy (RT) toxicities.

Materials/Methods: Patients with surgically excised ductal carcinoma in situ or invasive breast carcinoma receiving curative radiation were enrolled. Each patient completed an exercise behavior/QOL survey at two time points: before the patient’s 5th fraction of radiation and during the last week of treatment. Limb girth measurements to evaluate lymphedema and assessment of shoulder range of motion (ROM) were completed on all patients at the same two time points. Skin toxicity was assessed weekly throughout radiotherapy. Exercise behavior was quantified with the Godin Leisure Time Exercise Questionnaire (metabolic equivalent [MET] hours per week). Patients with >7 METs/week were designated the exercise cohort (n=10) and those with <7 METs/week the non-exercise cohort (n=10). PROs were measured using standardized questionnaires. Continuous variables were compared using the Wilcoxon rank sum test and percentages were compared using Fisher’s exact test.

Results: Median patient age was 56 (range 28-70) years. Median MET in the exercise cohort was 12.9/week (range 7.5-35.0, n=10); 0.0/week in the non-exercise cohort (range 0-5.8, n=10). Women in the exercise cohort experienced significant improvement in depression scores over the course of treatment as compared to those who did not exercise (p=0.013). Those in the exercise cohort also reported less fatigue on the FACT-Fatigue subscale at treatment completion (exercise: 133.0; non-exercise: 121.0) (p=0.6). In addition, only 30% of exercisers suffered from grade 2 dermatitis compared to 70% of non-exercisers (p=0.2), despite a similar body mass index (26.4 exercise cohort versus 28.1 non-exercise). Exercisers also had greater ROM in the affected (91.7 vs. 85.2%, p=0.1) and contralateral shoulder (95 vs. 90%, p=0.048) at treatment completion. No differences in pain or sleep scores were noted and lymphedema was mild (<3cm) in the entire patient cohort.

Conclusion: The vast majority of current exercise oncology literature indicates that physical activity is an independent predictor of quality of life metrics in cancer patients. Our study notes a trend towards improved outcomes with increased exercise during radiation therapy, suggesting that accrual of additional patients to our pilot study is worthwhile. Ultimately, a concurrent exercise intervention may improve quality of life and reduce acute toxicity in patients undergoing breast radiation treatment.
Chemotherapy-induced fatigue and mitochondrial function in early stage breast cancer

Namrata I Peswani1, Kanchana Herath1, Brian P Dranka1, George M Lessmann1, Donna McAllister1, Raymond G Hoffmann1, Balaraman Kalyanaraman1 and Christopher R Chitambar1. 1Medical College of Wisconsin, Milwaukee, WI.

Introduction

Patients with early stage breast cancer receiving chemotherapy (CT) may experience persistent fatigue. The mechanisms for fatigue are not well understood. We hypothesized that CT-induced fatigue may involve perturbations in mitochondrial function. We therefore examined the development of fatigue in patients during adjuvant or neoadjuvant CT and measured mitochondrial function in their peripheral blood mononuclear cells (PBMCs).

Methods

Females with Stage I-III breast cancer patients, ages 35-75 years, were enrolled in an IRB-approved study. Patients with coexisting illnesses associated with chronic fatigue were excluded. Patients self-reported fatigue severity using the 14-question Fatigue Symptom Inventory (FSI) that rates fatigue intensity on a 10-point scale. Data [FSI and PBMCs] were collected prior to CT, mid-point in the course of CT, 2 - 3 weeks after completion of CT, and 3 and 6 months later. Mitochondrial function in PBMCs from patients was measured using a Seahorse Bioscience XF24 analyzer at corresponding times.

Results

Results on CT-induced fatigue are available for 67 patients. The overall fatigue score for each patient was measured as the sum of the scores for all 14 questions in the FSI. The average fatigue score for the 67 patients prior to chemotherapy was 20. Baseline fatigue scores for patients who had adjuvant CT were much greater than for patients receiving neoadjuvant CT (R2=1). Patient fatigue scores doubled after starting chemotherapy (average score 40, p < 0.001). Even though fatigue scores improved after treatment completion (average score 26 at 6 months), the scores did not return to baseline 6 months later (p=0.02). In our population, CT-induced fatigue did not correlate with patient age regardless of the CT regimen [r=0.3 and r= -.2, for doxorubicin plus cyclophosphamide (AC) vs docetaxel plus cyclophosphamide (TC) groups, respectively]) or a decrease in hemoglobin (r= -.3 and r=0.03, for AC and TC, respectively). None of these correlations could explain more than 9% of the change in treatment-induced fatigue (p=0.2).

Preliminary analysis of mitochondrial function in 12 patients shows that 9 patients had a decrease in mitochondrial reserve capacity with an increase in CT-induced fatigue following completion of 4 cycles of CT. 3 patients had a decrease in mitochondrial reserve capacity but reported no significant change in their fatigue scores. Mitochondrial function data on all patients have been collected and are presently being analyzed.

Conclusion

Our study shows that early stage breast cancer patients treated with adjuvant or neoadjuvant CT may experience fatigue that can persist for months after completion of treatment and cannot be explained by the CT regimen, age, or anemia. Our initial results suggest a link between CT-induced fatigue and changes in mitochondrial function in some patients. Mitochondrial function analysis and its correlation with fatigue for all 67 patients will be completed and reported at SABCS. Mitochondrial function may prove to be a biomarker for CT-induced fatigue in certain patients and may help identify patients for whom interventions that stimulate mitochondria biogenesis, including pharmacologic agents and exercise, may be beneficial in ameliorating this side-effect.
Title: Psycho-oncological intervention in breast cancer patients - A quantitative analysis of tumor associated fatigue treatment

Christian Eichler1,2, Pia Multhaupt2, Sibylle Multhaupt2, Friedrich Wolff1 and Mathias Warm2,4. 1Holweide Hospital, Cologne, Germany; 2Brustzentrum, Krankenhaus Holweide, Cologne, Germany and 3University of Witten/Herdecke, Witten, Germany.

Body: Abstract

Background: Although tumor associated fatigue (TAF) or cancer related fatigue (CRF) is not a new concept, no real headway has been made in the quantitative analysis of its successful treatment. Since 20 to 30% of all breast cancer patients suffer from anxiety and/or depression within the first year of their diagnosis, this issue needs to be addressed and a standard treatment protocol has to be developed. Multimodal approaches are currently being used including increased physical activity, pharmaceutical therapy, and psycho-oncological intervention. This study focused on developing a simple, reproducible protocol for the psycho-oncological support of tumor associated fatigue patients.

Methods: Between the year 2011 and 2012, 23 breast cancer patients fulfilled the diagnosis TAF requirements and were introduced into this study. All patients had received surgery and were currently being monitored in an adjuvant setting. Our method focused on a psycho-oncological support group using a predetermined, highly structured and reproducible treatment manual. Eight weekly, 90 minute sessions were conducted and patients were evaluated before and after this eight session block. Tumor fatigue specific questionnaires such as the multidimensional fatigue inventory (MFI) as well as the hospital anxiety and depression scale (HADS) were used in order to quantitatively evaluate patient TAF.

Results: Of the 23 patients enrolled in the study, only 7 patients fulfilled the TAF diagnostic criteria after the psycho-oncological group treatment. This represents a 70% reduction in diagnosable tumor associated fatigue. The HADS analysis showed a 33% reduction in patient anxiety as well as a 57% reduction in patient depression levels. The MFI scores showed a significant reduction in 4 of the 5 evaluate categories. With the exception of the "mental fatigue" MFI category all results were statistically significant.

Conclusion: This study showed that a highly structured, psycho-oncological group intervention will produce significant improvements in breast cancer patient tumor associated fatigue levels after only 8 sessions. This type of group therapy should be recommended as a standard of care for all TAF breast cancer patients.
Title: Examining diagnostic and therapeutic delays using patient reported outcomes

Odicie Fielder-Kimbrough¹, Mayra Serrano¹ and Kimlin T Ashing¹. ¹City of Hope, Duarte, CA.

Body: Background: Diagnostic and treatment delays in cancer patients lead to poorer outcomes. African American and Latina women with breast cancer (BC) are more likely to experience delays. This study explores delays in African American and Latina breast cancer survivors (BCS) and association with physician-patient communication variables.

Methods: A total of 320 BCS (88 African-American and 232 Latina-American) diagnosed with stage 0-3 BC were recruited from the California Cancer Registry and Hospitals. BCS completed a questionnaire assessing patient reported time to diagnosis and initiating treatment, and quality of care variables pertaining to physician-patient interaction.

Results: The mean number of days waited after finding a lump or abnormality and seeking diagnostic care to obtaining a cancer diagnosis was 57.9 days in this cohort. Bivariate analysis revealed that Latina BCS were significantly more likely to wait longer to obtain diagnosis. \( p = .033 \). Once diagnosed, African-American BCS were more likely to report greater days delay to initiating treatment \( p = .007 \). The mean number of days delayed for initiating treatment between African American and Latinas, however, was not significantly different, 35.3 v. 34.5 days \( p=.107 \). We investigated the surgeon-patient dyad in influencing delays. The better patients rated the relationship, the fewer days in delayed treatment reported \( p=0.038 \). Additionally, 11% of BCS \( n=34 \) did not believe that their doctors gave them enough information regarding their treatment. The regression analysis showed that the patients' evaluation of the adequacy of doctors' information was a significant predictor of days delayed treatment \( p<0.0001 \). If the patient believed that enough information was provided, then the treatment was initiated within 6 days compared to the 40 days average reported by patients who endorse inadequate information.

However, the majority of patients (87%) reported a "good" or "very good" relationship with her surgeon. Although the majority of patients reported a "good" or "very good" relationship with her Oncologist (65%), the relationship was rated as "poor" or "very poor" by 23% of patients. There was no statistical difference in rating of relationship with providers between the ethnic groups \( p=.865 \).

Conclusions: Our results suggest that poor patient-physician interactions are associated with BC diagnostic and therapeutic care delays in both African American and Latina BCS. As healthcare shifts towards improving variables of quality of care and patient satisfaction, attention to improving these interactions and further exploration will be warranted. Further, improving timely access to diagnostic and therapeutic care may reduce BC disparity and improve cancer equity.
Title: Socioeconomic factors and the use of complimentary and alternative therapies in patients with early stage breast cancer

Swetha Panati¹, Kamran Shahid¹, Kaylin S Watson¹, Lauren Adair¹, Sanjay Juneja¹, Kimberly Nguyen¹, Runhua Shi¹ and Gary V Burton¹. ¹LSU Health Sciences Centre- FWCC, Shreveport, LA.

Body: BACKGROUND: Treatments not considered a part of conventional cancer care are known as Complementary and Alternative Medicine (CAM) and are becoming increasingly popular. These CAM therapies, divided into Alternative Medical Systems (AMS), Mind-Body Interventions (MBI), Biological Based Therapies (BBT), Manipulative Therapies (MT) and Energy Therapies (ET), may or may not benefit patients (pts). Socioeconomic factors which may be associated with CAM use have not been well defined.

AIM: To further define socioeconomic factors associated with the use of specific CAMs in pts with early stage breast cancer.

METHODS: 513 early stage breast cancer pts were interviewed between 4/2012 and 6/2014 using an IRB approved survey. The pts were interviewed after completion of all adjuvant chemotherapy, radiation and at least 6 months of adjuvant hormone therapy. Data collected included pt demographics, age, race, employment, insurance, marital status, income, education, religion and residence. All pts had literacy testing using a validated reading test. Pts were questioned on the use of 36 specific CAMs within the 5 CAM divisions, why they chose to use CAMs, and their opinion relative to benefits. Chi square test was used to evaluate the data.

RESULTS: CAM use was common with 100% of pts using or participating in at least 1 CAM class. CAMS within the MBI division were used by most patients with statistically increased use seen in non-protestant religion and employed pts (p=0.02 and 0.04). BBT division use was associated with age (p=0.001) and marginal for being insured (p=0.06). AMS use appeared to be more common in unemployed pts but was not statistically significant (p= 0.07).

The most common specific CAMs used were prayer (95%), exercise (65%), deep breathing (39%), and music therapy (38%). Statistically significant socioeconomic associations with specific CAM subclass utilizations included: Advancing age was associated with herbal supplement use. White pts used PET, music and art therapy as compared to black pts who used dance therapy and progressive relaxation. Insured pts used herbal, yoga and pilates. Pts with high income participated in yoga while low income used deep breathing, progressive relaxation, music and dance therapy. Pts with higher reading level (education) used deep breathing, music, dance and pet therapy.

CONCLUSION: All pts, with early stage breast cancer, utilize CAMs and see their use as an important part of their cancer therapy. Specific CAM subgroups use was associated with advancing age, employment, income, race and reading levels. Although all pts use CAM therapy, the vast majority of CAMs pose no risk and could benefit the individual pt. Utilization of various herbal supplements, which could pose a risk, is seen in all socioeconomic groups, however, a statistically significant increased use was seen with advancing age and having insurance. This study, however, did not obtain information from the 2% of pts seen at our institution who abandoned all conventional therapy and were lost to follow-up.
Breast cancer in young women: Fertility preservation as a component of treatment planning and discussion

Hugo Nunes¹, Fátima Vaz¹, Margarida Brito¹, Cláudia Melo², Ana Teresa Almeida Santos² and António Moreira¹. ¹Serviço de Oncologia Médica do Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal and ²Serviço de Reprodução Humana do Centro Hospitalar da Universidade de Coimbra.

Body: Background: As part of education and informed consent before cancer therapy, health care providers should address the possibility of infertility with patients (pts) treated during their reproductive years, and be prepared to discuss fertility preservation options and/or to refer all potential patients to Reproductive Specialists. Here we describe the recently established referral protocol of our institution with a fertility preservation centre. Both institutions belong to the Portuguese National Health System.

Methods: The referral protocol includes female pts, ≤ 39 years old, with a diagnosis of breast or gynecological cancer or sarcoma with indication to curative intention chemotherapy. The possibility of fertility preservation is primarily discussed at the cancer centre and only interested pts are referred to the reproductive clinic, where specialized counseling is provided. Fertility preservation procedures (FPPs) (oocyte, embryo and/or ovarian tissue cryopreservation) are conditional to a previous evaluation of the ovarian pool (OP). OP markers are: antral follicle count, follicle stimulating hormone (FSH) and anti-mullerian hormone (AMH). Only good prognosis cases are eligible for FPPs.

Results: After primary discussion with eligible breast cancer (BC) pts, 17 were referred to the reproductive clinic: median age at BC diagnosis was 34 yrs (29-38), median previous pregnancies number of 0 (0-2) and median number of children of 0 (0-2). Marital status: most (64%) pts had a companion but 36% did not. All pts except 1 were candidates for immediate chemotherapy, either in the adjuvant or neoadjuvant setting. In the adjuvant setting (9 pts), median time from surgery until starting systemic treatment was 61.5 (43-146) days (approx. 8.8 weeks); the case with a 146 day interval before chemotherapy was due to surgical complications and not to FPP. In the neoadjuvant setting (5 pts), median time between multidisciplinary decision and systemic treatment beginning was 17 (11-24) days (2.4 weeks). One patient was proposed to hormone therapy only after BC surgery and underwent FPP before systemic treatment. The timing for primary discussion of FPP was in multidisciplinary decision consultation. After counseling at the reproductive clinic, 2 pts declined FPP (%). For the other 13 pts oocyte cryopreservation was the FPP mostly used, although in one case embryo cryopreservation was performed. One case of ovarian hyperstimulation syndrome was observed but this FPP complication resolved without sequela and this event did not cause delay in chemotherapy treatment.

Conclusions: Our collaboration protocol allows for an efficacious referral of BC pts seeking fertility preservation counselling. Although BC patients may be focused initially on their cancer diagnosis, health care providers are encouraged to advise them regarding potential threats to fertility. Formal collaboration between cancer and reproductive centres, like the one described here, are crucial so as to allow for the widest array of options for fertility preservation and to prevent delay in cancer treatment. We intend to follow up these patients in order to realistically understand the impact of this practice in fertility and quality of life of cancer patients.
Deevakar Rogith¹, Rafeek A Yusuf¹, Shelley R Hovick², Bryan M Fellman³, Susan K Peterson³, Allison Burton-Chase⁴, Yisheng Li³, Elmer V Bernstam¹ and Funda Meric-Bernstam³. ¹University of Texas School of BioMedical Informatics, Houston, TX; ²Ohio State University, Columbus, OH; ³University of Texas MD Anderson Cancer Center, Houston, TX and ⁴Albany College of Pharmacy, Albany, NY.

INTRODUCTION: Breast cancer patients and providers are increasingly interested in personalized cancer therapy. Information-seeking behaviors and knowledge about personalized cancer therapy, cancer genetics, and molecular testing may influence patients’ participation in clinical trials and decision making regarding their care. We evaluated breast cancer patients’ knowledge and information seeking behaviors regarding personalized cancer therapy (PCT).

METHODS: The study population included newly registered female breast cancer patients at The University of Texas MD Anderson Cancer Center prior to their first clinical visit. Of 308 consecutive patients who were invited to participate, 100 (32%) completed a self-administered questionnaire assessing their knowledge and information seeking preferences regarding PCT. Knowledge regarding cancer genetics and PCT research was assessed using 16 true/false questions (Cronbach’s $\alpha=0.88$). A knowledge score was computed from the total number of correct responses.

RESULTS: Respondents were predominantly white (70%), older (median age 55 years; SD=12.9; range 26-84), educated (78% with college degree or higher) and higher incomes (54% >$50,000/year); 71% had been diagnosed with breast cancer for at most one year at time of participation. Knowledge regarding cancer genetics and PCT was moderate (M=8.68, SD=3.8). Although most participants (85%) could correctly identify the definition of PCT, many (59%) did not know that somatic mutations are not hereditary. Many (75%) knew that molecular testing can reveal risk for other hereditary cancers. Less than half (46.5%) knew about the availability of PCT in clinical trials. A minority (27%) indicated that they had sought information regarding PCT. They sought for information related to specific treatment options. Higher education (p<0.01) and income levels (p<0.05) were associated with higher knowledge scores and with seeking PCT information (p<0.01). Those who had previously undergone any genetic testing also were more likely to seek information about PCT (29.6% vs 9.9%, p<0.05). Other demographic and clinical variables like age, race, duration of illness, cancer stage did not correlate with the knowledge score or information seeking behavior.

CONCLUSION: Study participants could define PCT, but had limited knowledge of its availability and underlying treatment principles. This may be due, in part, to the fact that few participants had sought information about PCT. Understanding patients’ knowledge and prior information seeking regarding PCT may inform clinicians, who are likely to be patients’ initial source of information about PCT.
Body: Objective: Breast cancer is one of the most common cancers, and it accounts for 20% of malignant tumors of women. Psychological damage of the breast cancer patient is serious. In our institution, approximately 30% of the early breast cancer patients diagnosed as depressed mental status before operation. Breast cancer patients have to receive hormone therapy, chemotherapy, and radiation therapy for a long term after operation. Depressed mental status affects execution of the treatment, and the interruption of the treatment brings the risk of cancer recurrence. As a treatment for depressed mental status of cancer patients, medication and psychotherapy are common, but some previous reports showed exercise is effective. Exercises provided in these reports were various kinds and strength, and the standard prescription is not established. We investigate the effect of walking program as a mild aerobic exercise, whether it improves the depressed mental status and quality of life (QOL) of breast cancer patients.

Methods: 25 early breast cancer patients were recruited. Depressed mental status and QOL were assessed by Center for Epidemiologic Studies Depression Scale (CES-D) and Medical Outcomes Study 36-item Short Form Health Survey (SF-36). Physical activity was measured by accelerometer (Lifecorder PLUS, Suzuken), and estimated using metabolic equivalent foe task (MET). Participants mounted accelerometer after discharge, and baseline physical activity was recorded till 1 month after operation. After recording baseline physical activity, we instructed to perform walking or mild aerobic exercise. Scores of CES-D and SF-36, and physical activity data were measured again after two months.

Results: Physical activity after intervention was significantly increased as compared to baseline (8.5±5.5 vs 12.3±6.9 MET.h/week, p=0.02). At pre-operation phase, nine patients (36%) regarded as depressed mental status by CES-D, and depressed patients decreased to five at the time of 3 months after operation. A subscale of SF-36 (mental health) reduced significantly compared with pre-operation and 3 months after operation (p<0.01). Physical activity after intervention was correlated with the scores of CES-D and all subscales of SF-36.

Conclusion: This study demonstrated the possibility that walking program as a mild exercise improves mental status and QOL of perioperative breast cancer patients. It is necessary to examine in more detail for clinical application.
Title: Perception of women after undergoing microbiopsy following a positive breast cancer screening

Birgit Carly¹, Mireille Aimont¹, Nicolas Beauloye¹ and Fabienne Liebens¹. ¹CHU St Pierre, Brussels, Belgium.

Body: Background: Some authors have challenged the benefit of breast cancer mammographic screening due to high prevalence of overdiagnosis and overtreatment.

Purpose: To assess the anxiety and stress of women undergoing a microbiopsy following a false positive breast cancer screening and to evaluate whether this experience refrains them from continuing breast cancer screening.

Methods: 296 patients underwent breast microbiopsy for positive breast cancer screening B1, B2 and B3 lesions in our Breast Center between 2011 and 2013. Patients undergoing microbiopsy for B4 and B5 lesions were excluded from the study. The patients were thereafter interviewed by our two psychologists by phone within a time range of 6 to 18 months following the biopsy.

Results: 201 women answered the questionnaire (68% response). 5.5% had a breast lesion at risk and 75% had a benign lesion. Half of the women rated their anxiety as high (7-8 on a scale between 0 – 10) and 15% as very high (9-10/10) before the biopsy. While waiting for the result, 42% rated their anxiety as high (7-8/10) and nearly a third as very high (9-10/10). But 80% accepted to continue breast cancer screening and 90% would accept to undergo again a microbiopsy if necessary.

Conclusion: microbiopsy provides high stress in most patients undergoing it. Nevertheless, 90% of those who had a false positive results accept it and are willing to undergo a biopsy again if necessary.
Title: Exploratory post hoc analyses of patient-reported outcomes (PROs) in the IMELDA randomized phase III trial: Maintenance bevacizumab (BEV) ± capecitabine (CAP) after initial first-line BEV plus docetaxel (DOC) for HER2-negative metastatic breast cancer (mBC)

Dinesh Doval1, Saverio Cinieri2, Hakan Bozcuk3, Jean-Yves Pierga4, Kadri Altundag5, Xiaojia Wang6, Sudeep Gupta7, Guillermo Lopez Vivanco8, Vineet Gupta9, Ewa Chmielowska10, Jose Bines11, Philippe Montcuquet12, Alfred Namour13, Emilio Alba14, Giorgio Mustacchi15, Paulo Cortes16, Sabine de Ducela17, Ulrich Freudensprung17, Lesley Fallowfield18 and Joseph Gligorov19. 1Rajiv Gandhi Cancer Institute & Research Center, Delhi, India; 2Medical Oncology Department and Breast Unit, Brindisi, Italy; 3Akdeniz University Medical Faculty, Antalya, Turkey; 4Institut Curie, Université Paris Descartes, Paris, France; 5Hacettepe University Cancer Institute, Ankara, Turkey; 6Zhejiang Cancer Hospital, Hangzhou City, China; 7Tata Memorial Hospital/Center, Mumbai, India; 8Hospital Universitario Cruces, Vizcaya, Spain; 9Bangalore Institute of Oncology, Bangalore, India; 10Centrum Onkologii Prof. F Lukaszczyk, Bydgoszcz, Poland; 11Instituto Nacional de Cancer, Rio de Janeiro, Brazil; 12Clinique Saint Vincent, Besançon, France; 13National Cancer Institute, Cairo University, Cairo, Egypt; 14Hospital University Clinic Virgen de la Victoria, Málaga, Spain; 15Medical Oncology, University of Trieste, Trieste, Italy; 16University Hospital of Santa Maria, Lisbon, Portugal; 17F. Hoffmann-La Roche Ltd, Basel, Switzerland; 18Brighton & Sussex Medical School, University of Sussex, Falmer, United Kingdom and 19APHP Tenon, IUC-UPMC, Paris, France.

Body: BACKGROUND The addition of CAP to maintenance BEV demonstrated statistically significant and clinically relevant improvements in progression-free survival (PFS [primary endpoint]; HR 0.38 [95% CI 0.27–0.55]; log-rank p<0.001) and overall survival (OS [secondary endpoint]; HR 0.43 [95% CI 0.26–0.69]; log-rank p<0.001) in patients (pts) without disease progression (PD) on initial first-line BEV–DOC for HER2-negative mBC in the IMELDA trial. This benefit was achieved despite the smaller than planned sample size due to premature recruitment discontinuation because of regulatory withdrawal of BEV–DOC.

METHODS Pts with HER2-negative measurable mBC, ECOG PS <2, and no prior chemotherapy for mBC were eligible. After 3–6 cycles of BEV–DOC, pts without PD were randomized to either BEV alone or BEV–CAP (BEV 15 mg/kg q3w; CAP 1000 mg/m^2 bid d1–14 q3w) until PD. PROs (secondary endpoint) were assessed using the EORTC QLQ-C30 completed at screening (before BEV–DOC), at randomization to CAP vs no CAP, then every 3 cycles until PD, and at (but not beyond) PD. Analyses of mean change from randomization were prespecified. A 28-day window around the scheduled timepoints from randomization was applied to maximize the number of questionnaires available for analysis. Exploratory post hoc analyses included mixed-model repeated measures (MMRM; modeling weighted treatment effect from randomization across all available timepoints) and responder analyses using the global health status/QoL subscale. Pts were categorized as having improved (≥10-point increase), stable (change of <10 points), or worsened (≥10-point decrease) scores from randomization [Osoba, 2005].

RESULTS Adherence with questionnaire completion was 65–85% for all assessment timepoints during the first year of maintenance therapy. MMRM analysis of the global health status/QoL subscale showed no difference between the treatment arms in change from randomization (least squares mean estimate 0.40 [95% CI −6.07 to 6.87]). Similar results were observed for other subscales, including the diarrhea symptom subscale.

*No. of patients with completed questionnaires at both randomization and the respective week. Only weeks with ≥10 pts in both arms shown.*

**CONCLUSIONS** The IMELDA sample size was smaller than planned but protocol adherence with PRO completion was relatively high. Prespecified change from randomization and exploratory post hoc MMRM analyses of PROs suggest that the clinically meaningful PFS and OS benefit from adding CAP to BEV is achieved while maintaining QoL, with no difference between BEV and BEV–CAP treatments. Responder analyses over time showed improved or stable global health status/QoL scores in the majority of pts at each timepoint in both treatment arms.
Title: Stage-related risk categorization and influence of free margins on survival in triple negative early breast cancer - a population-based study of 2037 TNBC patients with adjuvant chemotherapy

Peter Kern1,2, Gunter von Minckwitz1, Carolin Pütter1, Annika Flach1, Sofia Pavlidou1, Rainer Kimmig1 and Mahdi Rezai2. 1German Breast Group, Neu-Isenburg, Hessen, Germany.

Body: Introduction: Triple negative breast cancer (TNBC) represents 10-20% of all breast cancer entities [1][2] and has a known aggressive behavior and poor outcome. Patients treated in the setting of randomized clinical trials often do not represent actual treatment characteristics in real-life scenarios. To determine the stage-related survival and effect of surgical performance in TNBC with current multimodal treatment, we set out to analyze data of a large population-based registry of primary breast cancers which covering >50% of all breast cancer cases in Germany.

Patients and methods: We analyzed data from a prospectively collected cancer registry of >200 certified breast units of the West-German Breast Center (WBC) in Germany from 2009-2011. From a cohort of 39570 primary breast cancer patients treated in this period, 12759 underwent adjuvant systemic therapy, out of which 2037 were TNBC cases with adjuvant chemotherapy. Inclusion criteria were triple negative breast cancers (Her2-new1+/2+ (Fish negative) and estrogen receptor (ER) and progesterone receptor (PR) <10%) and adjuvant chemotherapy, unilateral and non-metastasized breast cancer. Only those patients were included who have been followed-up within the first 3 years. Exclusion criteria were neoadjuvant chemotherapy, bilateral breast cancer and metastatic disease. The use of first, second and third generation chemotherapy was analyzed as well as the effect of clear/unclear resection margins and its impact on survival data.

Results: 2037 patients were eligible for this study. Overall survival rates were as follows: T1 a and T1b 100 %, T1c 90,7 %, T2 90,9 %, T3 68,1 % and T4 64,3 %. No statistical differences were detected in between stages T1 and T2, and also not in between T3 and T4. Combining T1/T2 and T3/T4 and performing group-wise comparisons, differences for combined stages were highly statistically significant (3.9 x E-09). Inflammatory TNBC was prognostically worst with a survival-rate of 33,3 % at 24-months. (p<0,001) Unclear resection-margins versus clear margins in TNBC exerted a negative impact on DFS (87 vs. 73 %; p=0,00002) and DDFS (p=0,0004). Age was an independent risk factor for survival with a cut-off at 35 years.(p=0,044) Third-generation chemotherapies (anthracycline+taxanes) were associated with a significant improved overall-survival at 24-months compared to first generation chemotherapies (non-anthracycline, non-taxane) (95 % vs. 87 %; p=0,0029)

Conclusion: Standard 3rd generation (anthracycline- and taxane-containing) chemotherapy and optimal surgical performance with clear margins is vital for patients with early, triple-negative breast cancer (TNBC). Within T1 and T2 stages, no stage-related deterioration of prognosis was detected, however these stages were markedly different from stages T3/T4, declining from 90-100% to 64-68 %.

This analysis of a large database of a population-based study demonstrates that tumor size, margins and guideline-adapted chemotherapy matter in triple-negative, early breast cancer.

Title: Nipple sparing mastectomy in patients with BRCA1 and BRCA2 mutations

Aidan T Manning¹, Andrea Pusic¹, Caitlin Wood¹, Anne Eaton¹, Michelle Stempel¹, Deborah Capko¹ and Virgilio Sacchini¹.  
¹Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Introduction: Nipple sparing mastectomy (NSM) is now performed with increasing frequency in both therapeutic and prophylactic breast surgery. The role of NSM in BRCA1 and BRCA2 mutation carriers has not been well described. The aim of this study was to review our experience with NSM in this high-risk population.

Methods: A review of the breast database was performed to identify all patients with documented BRCA mutations who underwent NSM at Memorial Sloan Kettering Cancer Center. Data extracted from the database included patient demographics, type of mutation, indication for surgery, type of reconstruction, and complications. For patients undergoing therapeutic mastectomy, data on disease stage, axillary procedures, and follow-up were also extracted.

Results: 177 NSMs (88 bilateral, 1 unilateral) were performed in 89 female patients with a documented BRCA mutation between September 2005 and December 2013. There were 56 patients with BRCA1 mutation, 26 with BRCA2 mutation, and 7 with genetic variants of uncertain significance. 26 patients had a therapeutic NSM for breast cancer (stage 0: n=6; stage 1: n=15; stage 2: n=5) and concurrent contralateral prophylactic mastectomy (CPM). The mean tumor size was 1.46cm (range, 0.1-3.5cm), and all were node negative following sentinel lymph node biopsy. 63 patients had NSM for prophylaxis. The mean age of patients undergoing therapeutic mastectomy was 41 years (range, 26-59) and prophylactic NSM was 39 years (25-59). There was an incidental diagnosis of ductal carcinoma in situ (DCIS) in 4 women undergoing CPM and 4 patients undergoing prophylactic NSM, including 1 patient diagnosed with bilateral DCIS, and an incidental diagnosis of atypia in 8 patients undergoing prophylactic NSM. In 26 patients undergoing therapeutic NSM, at median follow-up of 2.34 years (range, 0.45-6.06) there were no local or regional recurrences. One patient developed distant metastases and subsequently died from her disease, and 1 other patient died from metastatic ovarian cancer. In 63 patients undergoing prophylactic NSM, at median follow-up of 2.15 years (range, 0.11-8.14) there were no newly diagnosed breast cancers or deaths. Following NSM, 5 patients (5.6%) required subsequent excision of the nipple-areolar complex (3 cases for close or positive DCIS on final histology, 1 case for infection with necrosis, and 1 case for ongoing nipple discharge). All 89 patients had immediate breast reconstruction (tissue expander: n=80; permanent implant: n=8; autologous (DIEP) flap: n=1). Postoperative complications are shown in Table 1.

Postoperative complications following 177 nipple sparing mastectomies performed in 89 patients with BRCA mutations

Conclusion: NSM is an acceptable choice for patients with BRCA gene mutations undergoing therapeutic or prophylactic mastectomy with no evidence of compromise to oncological safety. This report shows an acceptable complication rate, and patients rarely required subsequent excision of the nipple-areolar complex.
Title: Variation in the use of mastectomy (MAST) in women with small node negative breast cancer (BC) treated at US academic institutions

Ines Vaz Luis¹,², Melissa E Hughes¹, Angel Cronin¹, Hope S Rugo³, Stephen B Edge⁴, Beverly Moy⁵, Richard Thériault⁶, Michael J Hassett¹, Eric P Winer¹ and Nancy U Lin¹. ¹Dana-Farber Cancer Institute, Boston, MA; ²Intituto de Medicina Molecular, Lisboa, NA, Portugal; ³University of California, San Francisco, CA; ⁴Baptist Cancer Center, Memphis, TN; ⁵Massachusetts General Hospital, Boston, MA and ⁶University of Texas MD Anderson Cancer Center, Houston, TX.

Body: Background: More than two decades ago several trials have shown equivalent survival between breast conserving surgery (BCS) and MAST. Among a contemporary cohort of patients (pts) with Stage I BC who would be expected to be candidates for BCS; we examined the initial choice of surgery and factors associated with it.

Pts and methods: Prospective cohort study including pts with clinical Stage I BC treated at a National Comprehensive Cancer Network center that participated in the BC outcomes database from 2000-09. Descriptive analyses were performed examining the proportion of pts who initially underwent MAST vs BCS. Factors associated with initial surgery were analyzed using multivariable logistic regression.

Results: Of 10,249 pts with clinical Stage I BC, 2,361(23%) underwent MAST as the initial surgery and 7,888 (77%) BCS. Of those, 8% were ultimately converted to MAST. The median time from diagnosis to initial surgery was longer among the MAST group (4 vs. 6 weeks).

Patient, tumor, care and institutional factors were associated with higher rates of initial MAST: 30% of pts with <50 years of age had a MAST vs. 17% of those ≥70; 41% of pts with body mass index (BMI) < 18.5 kg/m2 (underweight) had a MAST vs. 20% of those with a BMI ≥30 kg/m2 (obese). There was significant institutional variation, with rates of initial MAST ranging from 14-30%.

Differences by tumor subtype were observed, 38% of pts with HER2+/HR- tumors had initial MAST vs. 22-28% among other subtypes. In the multivariate model, age, BMI, comorbidity, income, center, stage, tumor subtype, grade, histology and preoperative MRI were associated with the choice of initial surgery.

Multivariate logistic model to investigate factors associated with initial MAST

Conclusions: Among a cohort of pts with small node negative BC, 23% elected to have MAST with significant variation associated with choice of treatment, while some of this variation is likely appropriate and clinically indicated, further studies to assess pt understanding of the tradeoffs between BCS and MAST is warranted. These findings need to be considered in light of the increasing number of pts who are choosing MAST/bilateral MAST.
Title: The role of preoperative MRI in negative margins after breast conserving surgery in patients with invasive breast cancer or purely DCIS

Elvira L Vos¹, Adri C Voogd², Cornelis Verhoef¹, Inge-Marie Obdeijn¹ and Linetta B Koppert¹. ¹Erasmus MC Cancer Institute, Rotterdam, Netherlands and ²Eindhoven Cancer Registry, Eindhoven, Netherlands.

Body: Introduction Clinical benefit of preoperative MRI in invasive breast cancer (IBC) patients and patients with purely ductal carcinoma-in-situ (DCIS) remains controversial. We aimed to study the role of preoperative MRI in negative margins after breast conserving surgery (BCS) and reexcision rate in a large population-based cohort.

Methods Retrospective analyses were performed in women diagnosed with IBC and purely DCIS and surgically treated between 2011-2013 extracted from the Eindhoven Cancer Registry. Patients were excluded in case of: neo-adjuvant systemic therapy, (clinical or pathological) tumor stadium T4, distant metastasis, and unknown resection margin status. According to preoperative MRI use, the study population was divided into a non-MRI and MRI group. All multivariable analyses were adjusted for baseline differences between non-MRI and MRI group with P<0.1. No information was available on the exact reason to perform MRI preoperatively in these patients.

Results A total of 3,116 patients were eligible of which 2,238 (71.8%) patients were treated by breast conserving surgery (BCS) and included for analyses. Preoperative MRI was performed in 592 (30.6%) IBC patients and 55 (18.3%) DCIS patients. In IBC patients, differences in non-MRI and MRI group were: median age (62 vs 58), histology (lobular type in 5.7% vs 24.5%), median tumor size (13 mm vs 15 mm), her2neu receptor status and specific tumor locations. Median (interquartile range) time between diagnosis and surgery in the non-MRI and MRI group were 21 (16-28) and 31 (22-40) days respectively (univariable and multivariable P<0.001). Negative margin was attained in 1,135 (84.4%) and 489 (82.6%) patients respectively (OR 0.88 95%CI 0.68-1.14 P=0.326). After adjustment for baseline differences and for factors associated with negative margin with P<0.1 (i.e. histology, tumor size, differentiation grade, progesterone receptor %, her2neu receptor status, regional lymph node stadium, and tumor location) MRI use was not associated with negative margin (OR 1.09 95%CI 0.81-1.45 P=0.587). Reexcision was performed in 96 (7.1%) and 62 (10.5%) patients (P=0.013). In case reexcision was needed, conversion to mastectomy occurred in 32 (2.4%) vs 20 (3.4%) patients (P=0.210). In patients with purely DCIS, only median age differed in non-MRI and MRI group (61 vs 57). Median (interquartile range) time between diagnosis and surgery in the non-MRI and MRI group were 22 (16-31) and 35 (23-49) days respectively (univariable P<0.001 and multivariable P=0.024). Negative margin was attained in 197 (80.1%) and 42 (76.4%) patients respectively (OR 0.80 95%CI 0.40-1.61 P=0.538). After adjustment for baseline differences and for factors associated with negative margin with P<0.1 (i.e. differentiation grade and tumor location) MRI use was not associated with negative margin (OR 1.51 95%CI 0.72-3.16 P=0.280). Reexcision was performed in 39 (15.9) and 10 (18.2) (P=0.672). In case reexcision was needed, conversion to mastectomy occurred in 12 (4.9%) vs 3 (5.5%) patients (P=0.859).

Conclusion In both IBC and DCIS patients, preoperative MRI delayed time between diagnosis and surgery, but was not associated with a higher percentage of negative margins after BCS.
Body: Introduction

Despite widespread adoption for the localization of impalpable breast lesions the wire guided localization (WGL) technique has a range of disadvantages including high re-operation rates. Radio-guided occult lesion localization (ROLL) has been proposed as an alternative technique, which may have superior clinical outcomes and be more flexible in its clinical application. A retrospective study of outcomes following ROLL therapeutic wide local excisions (WLE) and diagnostic excision biopsies (DEB) was performed. This documented 12 years experience of the ROLL technique at a single institution to provide a comprehensive analysis of the largest UK based series of ROLL excisions and sentinel node occult lesion localisations (SNOLL).

Methods

942 patients were identified who had been referred with non-palpable breast lesions from 2000-2012. 576 patients underwent WLE following a biopsy proven diagnosis of breast cancer. 366 patients underwent DEB. Prospective data collection was performed using bespoke proformas by the operating clinician. These data were supplemented with a retrospective analysis of prospectively collected data held on patient electronic records including evidence of radiological excision on specimen radiographs and histopathological characteristics including excision margin status. Sub-group analysis was performed to examine the outcomes from "same day" and "next day" protocols for ROLL/SNOLL procedures and to examine the effect of residual radioactivity levels in the excision bed on margin status.

Results

99.0% of ROLL WLE returned histological diagnoses of invasive cancer or DCIS and 98.4% of radiological abnormalities were identified on post-excision specimen radiographs. 97.5% of radiological abnormalities were identified on post-excision radiographs following DEB. Surgical localisation was rated as easy in 92.3% of excisions and 29 adverse events were recorded as a result of the localisation procedure (3.1%). Complete histological excision was recorded in 77.8% of the WLE sub-group based on defined margin criteria with a median specimen weight of 50g. 31.7% of DEB were pathologically upgraded to a diagnosis of breast cancer. No significant difference was seen in complete excisions rates between "next day" (76.4%, n=250) and "same day" (78.8%, n=326) ROLL protocols (p= NS). No significant difference was seen when levels of residual excision bed radioactivity and complete excision rates were compared (p=NS). Sentinel Lymph Node (SLN) localisation was successful in 97.6% of cases (n=205) with an SLN positivity rate of 12.7%. No significant difference was identified between SLN localisation rates for "next day" vs. "same day" SNOLL protocols (p=NS). The presence of microcalcification as the radiological abnormality (p=0.0005), underestimation of lesion size on pre-operative imaging (p=0.0005) and symptomatic referral (p=0.001) were factors that predisposed to incomplete excision margin status.

Conclusions

ROLL/SNOLL can be safely and effectively used to accurately localize impalpable breast lesions in agreement with current evidence. In addition to highly accurate localization, ROLL also has technical and logistical advantages that may make it more acceptable than WGL for clinicians and patients.
**Title:** Flat epithelial atypia on core biopsy and upgrade to cancer: A systematic review and meta-analysis

Anatoliy V Rudin¹, Hoskin L Tanya¹, Ann M Farrell¹ and Amy C Degnim¹. 'Mayo Clinic.

**Body:** BACKGROUND: Flat epithelial atypia (FEA) is a recently described breast lesion that may coexist with cancer or atypical ductal hyperplasia (ADH). Currently, there is no consensus on whether to surgically excise FEA diagnosed by core needle biopsy. Our aim was to perform a systematic review and meta-analysis of pertinent studies to determine the frequency of upgrade to cancer or ADH at surgical excision of "pure" FEA (no other high risk lesion on core biopsy).

**METHODS:** A retrospective search was performed using MEDLINE, Embase, Scopus and Web of Science databases from 1/2003- 4/2014 to capture studies on core biopsy diagnosed FEA followed by surgical excision. Search terms were: FEA, flat epithelial atypia, DIN1A, columnar cell, breast diseases, core needle biopsy. Inclusion criteria were: 1) manuscript with original data on FEA diagnosed on core needle biopsy, 2) data included outcome of cancer at surgical excision, 3) English Language.

**RESULTS:** Of 224 articles, 30 met inclusion criteria.

</table>
Across 1420 patients with pure FEA in 30 studies, observed proportions with upgrade to cancer varied from 0-40% with a pooled estimate of 11% (95% CI: 8-15%) using a random effects model. Test for heterogeneity was statistically significant (p < 0.0001, I² statistic=58%). After excluding 7 studies with <50% (or unreported %) of all FEA cases excised, heterogeneity decreased (p=0.07, I²=32%) and the pooled estimate of cancer upgrade was 9% (95% CI: 7-12%). For upgrade to ADH, 693 subjects with pure FEA were analyzed from 21 studies. The percent upgraded to ADH ranged from 0-60% with significant heterogeneity (p < 0.0001, I² = 64%). Excluding 4 studies with <50% of FEA cases excised did not improve heterogeneity (p < 0.0001 and I² = 66%). The random effects model pooled estimate of upgrade to ADH was 16% (95% CI: 11-23%) for the 21 studies and 17% (95% CI: 12-25%) for the subset of 17 studies.

CONCLUSION: The pooled upgrade rate of FEA to cancer was 9-11% and upgrade to ADH was 16-17%. For patients with FEA on core needle biopsy, surgical excision should be strongly considered.
Title: Prophylactic mastectomy in young women with breast cancer

Cristiane Metran Nascente¹, Frances Wright¹, Christel Helwig¹, Nim Li¹, Rodica Mandel¹, Alex Kiss² and Ellen Warner¹.
¹Sunnybrook Health Sciences Centre, Toronto, ON, Canada and ²ICES, Toronto, ON, Canada.

Body: Background: In recent years women with unilateral breast cancer (BC) have been increasingly requesting contralateral or bilateral prophylactic mastectomy (PM) despite only requiring unilateral mastectomy (M) or lumpectomy (L) respectively. This trend has been observed even in women at low risk for contralateral BC, particularly among younger women.

Objective: Determine the rates of ‘unexplained’ PM (UPM) and factors associated with this choice, among a prospective cohort of newly diagnosed young women with BC at our centre.

Methods: We reviewed the records of all patients diagnosed with BC at age ≤ 40 years from Feb ‘08 to Sept ‘13 at Sunnybrook who consented to have their clinical data entered in a prospective research database. Psychosocial data - HADS [Hospital Anxiety and Depression Scale] and IES [Impact of Event Scale] - were prospectively collected from all consenting women at baseline and at completion of active treatment. Among the 149 patients treated with curative intent, 43 received unilateral M, 59 L and 47 contralateral or bilateral PM. These groups were compared with respect to demographics, risk factors, use of pre-operative MRI, pathology, treatment and surgeon gender. Differences in variables between the groups were analyzed using analysis of variance for continuous variables and chi-square test for categorical variables.

Results: The mean age of all patients was 35 years old (21-40 range). Among the 47 patients who had PM, the first surgery was L for 15 (32%), unilateral M for 27 (57%) and bilateral M for 5 (11%). Twenty-four (51%) fulfilled high risk criteria (19 BRCA mutation, 4 strong family history, 1 chest radiation) and 2 (4%) had suspicious findings in the contralateral breast. The other twenty-one patients (45%) underwent UPM for "peace of mind" alone. Thirty-three (33%) of UPM patients had T3-4 tumors. There were no statistically significant differences between the UPM group and the combined M plus L groups, except for more multicentric/ multifocal disease in the UPM groups (43% vs 9% p≤0.0001).

Discussion: Fourteen percent of young women at our centre, a 1/3 with a relatively poor prognosis had UPM. Data correlating surgical choice with baseline and follow-up psychological variables will be presented. There appears to be a need for an educational/psychological intervention at the time of BC diagnosis for non-high-risk women contemplating preventive breast surgery to ensure that such a choice is truly informed.
Title: Initial experience with an ambulatory extended recovery program for patients undergoing mastectomy

Aidan T Manning¹, Danielle Cassella¹, Stacy Ugras¹, Beverly Tseng-Reyes¹ and Lisa Sclafani¹. ¹Memorial Sloan Kettering Cancer Center, New York, NY.

Body: Introduction: An ambulatory surgical program has been introduced at Memorial Sloan Kettering Cancer Center for patients undergoing select procedures that require a single overnight stay. The aim of this study was to review the initial experience with this program for patients undergoing mastectomy and to determine the rate and cause of unanticipated hospital admission.

Methods: All patients undergoing mastectomy with or without implant based reconstruction from March 2013 to February 2014 inclusive were entered into the Ambulatory Extended Recovery (AXR) program and data were recorded in a prospectively maintained AXR database. Data on patient demographics, type of procedure performed, and whether the patient remained on the AXR program were extracted. Electronic Medical Records were reviewed for all patients who required hospital admission in order to determine the reasons for this.

Results: 926 consecutive patients (905 female, 21 male) requiring mastectomy with or without implant based reconstruction were entered into the AXR program during this one-year period (mean age was 51 years, range 21-90). The procedures performed were as follows: bilateral mastectomy with reconstruction (n=433, 46.8%); bilateral mastectomy without reconstruction (n=48, 5.2%); unilateral mastectomy with reconstruction (n=255, 27.5%); and unilateral mastectomy without reconstruction (n=190,20.5%), with or without axillary procedures. Reconstructive procedures deemed suitable for the AXR program included tissue expander or permanent implant insertion only. 861 of 926 patients (93%) remained on the AXR program and were discharged following overnight stay. 62 patients (6.7%) (61 female, 1 male) did not complete the AXR program and required hospital admission (mean age, 52 years; range, 22-81). 3 additional patients (0.3%) required hospital admission on occasions that the AXR unit was at maximum capacity. Reasons for admission are shown in Table 1. Of the 26 patients with postoperative hematoma, 17 were brought back to the Operating Room for definitive management and 9 patients were treated conservatively. Following admission, most patients (52 of 62, 83.9%) were fit for discharge after 1 day. Of the remaining 10 patients, 9 were discharged after 2 days and 1 after 5 days.

Reason for hospital admission for 62 of 926 patients scheduled for breast surgery on the Ambulatory Extended Recovery (AXR) program

</table>

Conclusion: Unilateral and bilateral mastectomy, with or without implant based reconstruction, is safely performed in the setting of an AXR program. Only a small minority of patients will subsequently require hospital admission, most commonly for management of postoperative hematoma or inadequate pain control.

**Title:** Implication of breast-conserving therapy in the subtype era of breast cancer

Sanghwa Kim¹, Hyung Seok Park¹, Jee Ye Kim¹, Jegyu Ryu¹, Seho Park¹ and Seung Il Kim¹. ¹Yonsei University College of Medicine, Seoul, Korea.

**Body:**

**Background**

Molecular subtypes of breast cancer are one of the key factors to predict clinical outcomes in women with breast cancer. Some specific subtypes like triple-negative breast cancer (TNBC) show more aggressive behaviors and worse clinical outcomes than luminal A subtype, thus there are conflicting data regarding optimum local surgical strategy for TNBC. We evaluate the clinical outcomes of women who underwent breast-conserving therapy (BCT) compared to those underwent mastectomy regarding to breast cancer subtypes using a large single center cohort.

**Methods**

A total of 5353 women who underwent BCT or mastectomy due to primary breast cancer from 1990 to 2010 were retrospectively reviewed. Cases with initial distant metastases or those with neoadjuvant chemotherapy were excluded. Clinicopathological characteristics, overall survival (OS), and recurrence-free survival (RFS) were analyzed using the Chi-square test, Kaplan-Meier survival analysis, and log-rank test. Cox proportional hazard models were used for multivariate analyses. In order to explore the role of BCT in TNBC, we performed sub-group analysis using patients with TNBC in the cohort.

**Results**

BCT was performed in 1866 cases and mastectomy in 3487 cases. The mastectomy group had higher T stage (T2-3: 53.5% vs. 26.5%, p<0.001), higher N stage (N2-3 17.1% vs. 5.1%, p<0.001), and more HER2 over-expression (11.6% vs. 8.3% p<0.001) than the BCT group had. The BCT group consisted of more Luminal A and TNBC subtypes than the mastectomy group. (Luminal A 56.2% vs 41.6%, TNBC 19.9% vs 12.7%, all p<0.001)

The 5-year RFS rates of the BCT group in luminal A, B, and TNBC were better than those in the mastectomy group (Luminal A 93.7% vs 89.4%, p<0.001, Luminal B 94.9% vs. 86.3%, p=0.01, and TNBC 92.9% vs 79.8%, p<0.001). However, the 5-year RFS of HER2-enriched subtype was not significantly different according to the operation type (p=0.85). The BCT group in luminal A and TNBC showed better OS than the mastectomy group (Luminal A, p=0.002, TNBC, p<0.001), however, the difference of OS between the BCT and mastectomy groups in luminal B and HER2-enriched subtypes was not significant (p>0.05).

In multivariate analyses, T and N stage, breast cancer subtypes, histologic grade, and the status of adjuvant chemotherapy were independent prognostic factors for RFS and OS (all p<0.05). However, The statistical significance of RFS and OS of local therapy, BCT vs. Mastectomy, according to breast cancer subtypes in the univariate analyses disappeared in multivariate analyses (HR for RFS=0.90, 95%CI=0.70-1.16, HR for OS=0.83, 95%CI=0.614-1.122). In the sub-group analysis, BCT showed comparable outcomes compared to mastectomy in patients with TNBC in multivariate analyses. (HR for RFS=0.89, 95%CI=0.38-2.06, HR for OS=1.007, 95%CI=0.987-1.028)

**Conclusions**

Clinical outcomes were not affected by surgical approaches regarding to breast cancer subtypes. BCT is an acceptable surgical approach regardless of breast cancer subtype, and even in selective patients with TNBC.
Title: Assessment of diagnostic and therapeutic value of ductoscopy biopsy in single intraductal papillary lesion compared with open surgery

Zheli Xu¹, Wanying Xing¹, Qiang Li², Deli Xing³ and Yiqi Gu¹. ¹Breast Surgery of the 3rd Clinical Medical College of Norman Bethune Health Science Center of Jilin University, Changchun, Jilin, China; ²China-Japan Union Hospital of Jilin University, Changchun, Jilin, China and ³China-Japan Union Hospital of Jilin University, Changchun, Jilin, China.

Body: Purpose
Papillary lesions (PL) account for 1–2% of all breast neoplasms and fiberoptic ductoscopy is a practical and direct method compared with open biopsy in diagnosis and treatment of intraductal papillary lesions. This study aimed to assess efficacy of ductoscopy in the diagnosis and management of single intraductal papillary lesion.

Methods
A total of 232 patients at China-Japan Union Hospital of Jilin University who were diagnosed with single intraductal papillary lesion by fiberoptic ductoscopy were enrolled from March 2011 to November 2013. All patients underwent ductoscopic papillomectomy before open surgery. The final pathologic diagnoses were made by using specimen from both ductoscopic papillomectomy and surgeries. Any intraductal papillomatous lesion or surface abnormalities were considered as positive findings during ductoscopy.

Results
Histopathologic investigations of surgically excised or ductoscopically removed lesions revealed that 217 out of 232 cases were positive. In 187 cases pathological changes were only found in ductoscopic papillomectomy specimen, while the number of cases which was only found in open biopsy was 24. In 6 cases ductoscopic papillomectomy and surgeries specimen both showed positive.

Conclusions
The accuracy of ductoscopy biopsy in diagnosis was 88.9% (193/217) and specificity was 100%. In 187 out of 217 cases (86.2%) ductoscopic papillomectomy alone could completely remove the lesion. Ductoscopy is an effective tool for diagnosis and treatment of single intraductal papillary lesion.
Title: Multimodality perioperative analgesia with paravertebral nerve block and gabapentin reduces narcotic use and hospital length of stay in mastectomy patients

Zandra H Cheng¹, Vlad Frenk¹, Jennifer D Bishop¹, Theresa Bowling¹ and Helen A Pass¹. ¹Stamford Hospital, Stamford, CT.

Body: Postoperative pain control is the major determinant in hospital length of stay (LOS) in patients undergoing mastectomy. Using a multimodality approach for peri-operative analgesia (PA) with paravertebral nerve block (PVB)(regional anesthesia) as well as including pre- and postoperative oral gabapentin, we significantly reduced both LOS and narcotic usage (NU) when compared to PVB alone or conventional postoperative management (CPM) with on demand postoperative pain medications. A single institution, retrospective chart review of patients undergoing mastectomy from 2009 to 2014 was performed (n = 129; 84 bilateral, 45 unilateral) with a subset analysis performed on patients undergoing tissue expander (TE) reconstruction (n=86) or bilateral mastectomies (n=84). Patients were grouped by PA type (CPM, PVB by catheter infusion, and PVB with gabapentin (PVB+G)). Data were analyzed via using Student t-test and significance was defined as p<0.05. As seen in the table below, LOS and NU decreased with increasing multimodal PA approach. LOS was significantly decreased by PVB+G compared to CPM and PVB for all mastectomies, bilateral mastectomies, and mastectomies with tissue expander (TE) reconstruction. NU was significantly decreased by PVB+G compared to CPM and PVB for all mastectomies and bilateral mastectomies, and trended toward decreasing NU in TE reconstruction.

NU = narcotic use normalized to morphine sulfate

We have found employing a multimodality approach to PA with the addition of the GABA analogue, gabapentin, to regional anesthesia via PVB catheter infusion significantly improves the postoperative course of patients undergoing mastectomy procedures by decreasing LOS and NU.
Title: Does the implementation of an enhanced recovery programme impact on post-operative outcomes in populations with significant comorbidity and social deprivation?

Ee Von Woon¹, Adrian Wong¹, Juliette Murray¹ and Alison Lannigan¹. ¹Wishaw General Hospital, Wishaw, Lanarkshire, United Kingdom.

Body: Background:
Enhanced Recovery Programmes (ERP) are a well established evidence-based model of care which are intended to reduce the impact of surgery and safely reduce the length of inpatient stay for surgical patients. In Lanarkshire, Scotland, the ERP was introduced in Wishaw General Hospital in 2012 but has yet to be extended to neighbouring Monklands Hospital. We audited the impact of the ERP by comparing post-operative outcomes between these district general hospitals in the same health board servicing adjacent catchment areas which are both in areas of significant social deprivation.

Materials and Methods:
All patients who underwent breast surgery from August 2012 to August 2013 inclusive were identified from a prospectively collected electronic database. Parameters analysed included ASA grades, length of postoperative stay, rate of post-operative complications and re-admissions. The relative social deprivation of patients was calculated by cross referencing their postcodes with the Scottish Index of Multiple Deprivation (SIMD) 2012.

Results:
294 and 152 patients underwent 336 and 161 breast operations in Wishaw and Monklands respectively. The mean age of these patients was 57 in Wishaw and 54 in Monklands. 30% of patients in Wishaw and 19% of patients in Monklands had ASA grade 3 (range = 1 to 3, p=0.08). In both hospitals, the most common diagnosis was breast cancer (Wishaw: n=257, 76%; Monklands: n=110, 68%; p=0.17) and the most common procedure performed was wide local excision (Wishaw: n=235, 70%; Monklands: n=114, 71%; p=0.73). The mean postoperative stay was 0.9 days in Wishaw compared to 2.0 days in Monklands (p<0.001). Postoperative complications were higher in Monklands (n=37, 23%) compared to Wishaw (n=52, 15%, p=0.04). There was no significant difference in the ASA grades of patients who developed complications, rates of readmissions, A&E visits or reoperation (p>0.05). Although the Wishaw patient cohort is living in significantly more deprived areas (mean SIMD rank=2543) compared to the Monklands patient cohort (mean=2915, p=0.02), there was no significant difference in deprivation status between patients with complications in these two catchment areas (p=0.65).

Conclusion:
The ERP is a safe and effective protocol for breast surgery patients with low complication rates and its implementation halved the inpatient admission time in our cohort. The savings derived from this would outweigh the running costs of the ERP.
Title: Predictors of bilateral mastectomy in breast cancer patients

Yun Fu1,2, Zhigang Zhuang2, Michelle Dewing1,4, Apple Sophia3 and Chang R Helena1. 1Revlon/UCLA Breast Center, , David Geffen School of Medicine at UCLA, Los Angeles, CA; 2Shanghai First Maternity and Infant Hospital, Tongji University School of Medicine, Shanghai, China; 3David Geffen School of Medicine at UCLA, Los Angeles, CA and 4University of Colorado Health Breast Surgery, Colorado Springs, CO.

Body: Background: Breast cancer surgery has experienced an evolutilional change from radical mastectomy to conservative techniques due to the migration of stage of disease at diagnosis and adjuvant use of multimodality treatment. While breast conservation is preferred by most, the trend of bilateral mastectomy has been on the rise in the United States. The aim of this study is to determine factors that may affect patients’ choice of bilateral mastectomy.

Methods: This is a retrospective study of 376 patients diagnosed with primary invasive breast cancer who were treated by bilateral or unilateral mastectomy (BM or UM) at the Revlon/UCLA Breast Center between Jan. 2002 and Dec. 2010. Patients in the bilateral mastectomy (BM) group were further divided into groups of bilateral mastectomy for bilateral breast cancer and for unilateral breast cancer and contralateral prophylactic mastectomy.

Results: When compared with the UM group, the following factors were found to be associated with the BM: younger age (p<0.001), pre-menopause (p<0.001), having a family history of breast cancer (p<0.001) or ovarian cancer (p=0.017), BRCA 1 and 2 mutations (p<0.001, p=0.011, respectively), more breast biopsies (p=0.007), history of breast augmentation (p=0.014), more MRI study within 6 months before the surgery (p=0.029), more likely to have reconstruction surgery (p<0.001) and sentinel lymph node biopsy (SLNB) (p<0.001). Multivariate analysis indicated that patients with smaller tumor size (p<0.001, OR 0.087), negative nodes (p<0.001), sentinel lymph node biopsy as nodal surgery (p<0.001, OR 0.259), BRCA mutation (p=0.020, OR 6.537) and positive family history (p=0.001, OR 2.732) were more likely to choose bilateral mastectomy with reconstruction using tissue expanders or implants (p<0.001, OR 4.546).

Conclusion: Bilateral mastectomy is associated with lower TN stage, requiring only SNLB, presence of BRCA mutation and/or high risk family history. Tissue expanders or implants based reconstructions were more frequently chosen by patients with bilateral mastectomy.
Title: Does therapeutic mammoplasty reduce mastectomy rates?

Jennifer Pollard¹, Pang Wong¹, James Mansell², Juliette Murray¹, Alison Lannigan¹, Julie Doughty², Laszlo Romics³, Sheila Stallard² and Christopher Wilson². ¹NHS Lanarkshire, Wishaw; ²Western Infirmary, Glasgow and ³Victoria Royal Infirmary, Glasgow.

Body: Introduction: Therapeutic mammoplasty (TM) is increasing in popularity as a method for enhancing breast conserving surgery. Studies have shown it’s oncologically safe, whilst improving cosmetic outcome1,2,3. Therapeutic mammoplasty has been gaining popularity in West of Scotland over the past five years. Initially it was thought this may reduce requirement for mastectomy and immediate reconstruction. We have recorded type of surgery patients would have required had they not been suitable for TM, looking at changing demographic of surgical workload.

Methods: Prospective data collected about patients undergoing TM in West of Scotland since 2011 in Victoria Infirmary, WesternInfirmary and in NHS Lanarkshire. We reviewed clinical indications for TM, surgical alternative, Body Mass Index (BMI) and smoker status.

Results: Seventy-nine patients were identified. In 67 cases, alternative surgical option of mastectomy or standard conservation was recorded. Mean BMI was 29. 41% of patients had contralateral surgery for symmetry at the same time. In 28 cases (35%) TM avoided need for mastectomy. In 39 cases (49%) it was felt that cosmetic result would be improved by TM compared with standard conservation. During the study period, rates of mastectomy with immediate reconstruction as a proportion of total number of treated cancers have remained similar.

Conclusions: Whilst introduction of therapeutic mammoplasty in our region has improved options offered to patients and likely cosmetic outcomes, it has not had a major impact in reducing mastectomy rates or demand for immediate reconstruction. It has probably increased surgical workload of plastic surgeons as these cases are often performed as joint procedures.

Title: Intraoperative ultrasound guided wire bracketing of nonpalpable breast lesions for excision

David T Rock¹, Aimee L Stewart¹ and Samith Sandadi¹. ¹Regional Breast Care, 21st Century Oncology, Fort Myers, FL.

Body:

Background. Mammographic wire localization is the primary means of localizing nonpalpable breast lesions for excision. Unfortunately, that procedure is associated with patient discomfort and vasovagal responses, scheduling difficulties, and problems with inaccurate wire placement or wire displacement. In addition, the wires often enter far from the target and take an indirect course resulting in high positive margin rates. We reviewed our experience with intraoperative ultrasound guided bracketing of nonpalpable lesions to determine if the accuracy of the excision and patient factors could be improved.

Methods. Patients that underwent intraoperative ultrasound guided wire bracketing were identified by electronic chart review. After the patient was anesthetized, high frequency linear array ultrasound was used to identify the target lesion. Under direct ultrasound visualization, the lesions were bracketed with 4 hook-wires placed perpendicular to the chest wall at the radial and antiradial margins of the lesion. Excision of the lesion was then performed with circumferential dissection around all 4 localization wires.

Results. Intraoperative localization was planned on 119 patients. The lesion was identified by preoperative ultrasound in 110 of those patients (92%). The remaining patients required mammographic localization. In 43 patients (85%) the lesion was identified for bracketing, in the remaining 17 patients the biopsy clip was seen by ultrasound and bracketed. Only 3 patients had positive margins (no tumor touching ink) requiring re-excision (2.7%).

Conclusions. The results of our experience show that intraoperative ultrasound guided wire bracketing is a reliable alternative to mammographic localization and is associated with a lower positive margin rate than reported for mammographic wire localization with a single wire. In addition, patient comfort is improved, cost is reduced, and there are no scheduling issues. The technique is especially useful for oncoplastic excisions where the incision is remote from the target lesion.
Title: Impact on survival of primary tumor resection in women with de novo metastatic breast cancer. The GEICAM Alamo I-III breast cancer registry (1990-2001)

Body: Introduction: Retrospective data from institutional series and population-based databases have suggested a potential benefit of the primary tumor (PT) surgery in de novo metastatic breast cancer (MBC) patients (pts). Recently reported prospective data from 2 randomized trials and a multicenter registry questioned the real role of the local approach in the modern individualized systemic treatment era. Methods: The ALAMO (A) is a retrospective analysis of pts diagnosed with BC between 1990 and 2001 across 56 GEICAM hospitals in Spain. Patterns of BC presentation (tumor and host characteristics), treatment and survival were recorded in 3 cohorts, AI (1990-93, 4529 pts, closed by 2000), AII (1994-97, 10453 pts, closed by 2003) and AIII (1998-2001, 10675 pts, closed by 2007). MBC pts at first diagnosis excluding those without complete information about their PT surgery were included. Descriptive, Kaplan-Meier and Cox regression analyses were carried out. Results: 5.5% (N=1415) of the ALAMO database pts were initially diagnosed with MBC, 1331 fulfilled the present analysis criteria (327 from AI, 619 from AII and 385 from AIII). Median age was 63.1 years (range: 21.6-96.0), 51.8% had single-organ metastasis, and their distribution according to the predominant site of disease was skin/soft tissue (16.2%), bone (33.7%), and visceral (48.4%). Surgery of the PT was done in 44.5% (N=592) of pts (512 with radical procedures, 46 with palliative procedures and 34 unknown); besides, 427 pts underwent axillary dissection. Initial local treatment was the choice for 380 pts (358 surgery and 22 radiotherapy), 722 received initial systemic therapy (480 chemotherapy, 214 endocrine treatment and 28 both), 29 received best supportive care and for 200 pts the treatment sequence could not be established. Pts in the surgery (S) group were younger (19.5% vs 11.8% were <44 years-old in the S vs non-S group respectively), with oligometastatic disease (61.9% vs 43.9% with single-organ involvement in the S vs non-S group respectively) and with different sites of disease (40.2% vs 54.3% with visceral and 39% vs 29.8% with bone metastasis in the S vs non-S group respectively). With a median follow-up of 1.9 years, the 5-yr overall survival (OS) was 25.4% in the entire de novo MBC population, with a median OS of 3.3 yrs in the S-group vs 1.9 yrs in the non-S-group (HR 1.69, p<0.0001). Subgroup analyses showed a benefit of PT surgery in OS regardless the number of metastasis and site of disease, but didn't show this benefit analyzing pts according to BC subtypes. The multi-adjusted HR for surgery was 1.38 (p=0.037). The multivariate Cox regression analysis model included the site of disease (p=0.028), the histopathologic grade (p=0.019) and the hormone receptor status (p=0.007). Discussion: The Alamo data line up with previously reported population-based registries, which highlight the better survival outcome of de novo MBC pts undergoing PT surgery. However, the consideration of the biological heterogeneity of BC has changed the landscape of systemic treatment. Only well designed randomized controlled trials will have the power to discriminate between a consistent bias and a real biologic effect of the PT surgery.

Title: Oncologic outcome of 2,217 patients with breast cancer after negative sentinel lymph node biopsy without axillary lymph node dissection

Jong Tae Park¹, Hak Min Lee¹, Sung Gwe Ahn¹, Seung Ah Lee² and Joon Jeong¹. ¹Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea and ²Eulji general Hospital, Eulji University College of Medicine, Seoul, Korea.

Body: Background
Sentinel lymph node biopsy (SLNB) is a standard method for nodal staging and enables to omit axillary lymph node dissection after negative sentinel lymph node (SLN). False-negative rate of SLNB has been reported as 5-7%. To dissolve the concerns regarding the axillary recurrence due to false-negative cases after negative SLNB, we investigated oncologic outcomes of a large number of breast cancer patients with negative SLN after SLNB.

Methods
A total of 2,475 patients with clinically node-negative breast cancer underwent SLNB at Severance hospitals between December 1998 and December 2013. ⁹⁹m Tc radiocolloid or blue dye was used in SLNB with periareolar intradermal injection technique. Intraoperative frozen examination of SLN was performed. If frozen test for SLN showed negative result, further axillary node dissection was omitted. Survival rates were estimated by the Kaplan-Meier method. Multivariate survival analysis was performed using the Cox-regression hazard model.

Results
Among 2,475 patients, 2,217 patients had no metastatic focus on SLN. A mean of 2.4 sentinel lymph nodes was dissected in all of the patients. At a median follow-up of 36 months, only 13 patients (0.6%) had axillary recurrence, and a median time to the recurrence was 20 months (range 7-45 months). During the follow-up period, 22 local, 16 regional, and 44 distant recurrences were observed. In multivariate analysis for axillary recurrence, tumor size and refusal of systemic therapy were demonstrated to be independent risk factors for axillary recurrence (hazard ratio (HR) 1.77, 95% confidence interval (CI), 1.08-2.89, \( P=0.024 \); HR 0.15, 95% CI, 0.03-0.75, \( P=0.021 \)). Disease-free survival and axillary recurrence-free survival rates at 3 years were 96.5% (95% CI, 0.960-0.970) and 99.2% (95% CI, 0.990-0.994), respectively.

Conclusions
The axillary recurrence rate was very low in patients with negative SLN. Our findings supported that SLNB is a reliable procedure and its oncologic safety is not affected by the chance of axillary recurrence after negative SLNB.

Clinical presentation included: Palpable mass, nipple discharge, itching, mammographic mass asymmetry or calcifications. This study found 69.3% of papillary lesions presented as mammographic findings including nodules asymmetry (28%), calcifications (24%), masses (16.7%). The remaining 29.3% of the papillary lesions presented as palpable masses (14.7%), discharge (4%), itching (2.67%), and pain/tenderness (1.3%).

Conclusion: IDPs present as a radiologic finding in 2/3 of the cases and a clinical complaint in the remaining patients. A review of the upgrade rates in the literature shows a range of 0-39%. Although larger cores from vacuum assisted biopsies may lower the upgrade rates, a good number of studies show rates that do not justify observation only. As concerning is the association of papillary lesions with atypia and malignancy in 32.3% of our patients indicating a possible causal relation. Our data and review of the literature indicate that short of a prospective randomized trial to settle this question, IDPs should be routinely excised.
Title: Randomized clinical trial comparing 2-octylcyanoacrylate versus intradermic suture with nylon: Similar cosmetic results with different safety profile

Ruffo Freitas-Junior¹, Thiago S Becker¹, Rosemar MS Rahal¹ and Regis R Paulinelli¹. ¹Federal University of Goias (UFG), Goiania, Goias, Brazil.

Body: Introduction: There are multiple options available for closing surgical incisions. This study compared the cosmetic results between the use of 2-octylcyanoacrylate and nylon sutures in elective breast surgery. Objectives: To compare the efficacy and cosmetic outcome between the adhesive and conventional suturing with nylon on the cutaneous synthesis mammary surgeries. Methods: we performed a prospective, randomized, controlled trial with 79 patients, 37 in group 2-octylcyanoacrilate and 42 in the group with nylon suture. We evaluated the surgical aspect of the scar in 40 and 180 days, the occurrence of complications (such as dehiscence, hematoma, infection and allergic reactions), the size of the wound and breast lesions, surgical time and skin closure time, hemoglobin and preoperative WBC, age, height and weight of patients. Statistical analysis was performed by t test and chi-square. Results and discussion: the study was stopped before the end of the recruitment of patients for the presence of a greater number of dehiscence in the adhesive group (OR: 11.42, 95% CI 1.36 - 96.02, p=0.007). There were no significant differences between the groups regarding other complications, not in relation to surgical time and the aesthetic appearance of scars after 40 and 180 days. The average size of the wound was greater in the adhesive group than in the suture, being respectively 32.97 (+ 10.54) mm and 27.64 (+ 9.56) mm, no correlation of size with the largest number of dehiscence. Conclusion: The results showed that the cosmetic scar appearance of 2-octylcyanoacrilate is equivalent to those obtained with the intradermal nylon suture, but the risk of dehiscence is higher.
2014 San Antonio Breast Cancer Symposium

Title: Multiple radioactive seed localization in breast conserving surgery for multifocal or extensive DCIS

Raquel F van la Parra¹, Claudette E Loo¹, Natasja Janssen¹, Emilie Groen¹, Marieke J van den Berg¹, Hester S Oldenburg¹ and Marie-Jeanne T Vrancken-Peeters¹. ¹Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Noord-Holland, Netherlands.

Body: Background: Radioactive seed localization (RSL) has been introduced as an alternative to wire localization for guiding surgical excision of nonpalpable breast lesions. The goal was to determine whether the use of multiple seeds makes conservative management of the breast in case of extensive or multifocal ductal carcinoma in situ (DCIS) feasible.

Methods: A retrospective chart review was performed which included women with confirmed pure DCIS undergoing multiple seed RSL followed by breast conserving surgery (BCS). Outcome measures included positive margin and re-operation rates, specimen weight and the need for oncoplastic reconstruction after resection of the primary lesional area.

Results: Between January 2008 and September 2013, 28 patients with DCIS were localized with multiple (≥ 2) 125I seeds. Multiple seeds were implanted because of multifocal DCIS in 12 patients (42.9%) or because of extensive DCIS in 16 patients (57.1%). Seventeen patients (60.7%) underwent simultaneous oncoplastic reconstruction.

The mean specimen weight was 81.5 grams (median 64, range 12- 340 grams), and varied from 42.4 grams (median 35, range 12 - 101 grams) in the patients without oncoplastic reconstruction to 103.5 grams (median 84.5, range 46 - 340 grams) in the patients with oncoplastic reconstruction. The positive margin rate was 25% (7/28). Of these, 3 were focally positive and 4 were more than focally positive and required a re-excision.

Conclusions: By using multiple 125I seeds to localize extensive or multifocal DCIS, breast conserving surgery becomes an effective and safe option in this group of patients with acceptable outcome measures.
Title: Treatment of benign breast tumor with ultrasound-guided radiofrequency ablation

Zheli Xu1, Denghua Sun1, Guang Sun1, Yanxi Liu1 and Xinyu Feng1. 1Breast Surgery of the 3rd Clinical Medical College of Norman Bethune Health Science Center of Jilin University, Changchun, Jilin, China.

Body: Purpose To evaluate the safety and efficacy of radiofrequency ablation (RFA) as a therapy for benign breast mass in terms of ablation lesion size and temperature.

Methods This study had institutional review board approval, and written informed consent was obtained. A total of 230 patients (122 solid cases and 108 cystic cases) with core-needle biopsy-proved in benign breast masses were enrolled. Under US-guidance, the RF energy was delivered through a 15-mm 13-gauge monopolar tip needle electrode by using the temperature-controlled mode. 80°, 85°, 90°, 95° were maintained for 10 minutes. The tumor and surrounding breast tissue were ablated with a saline-cooled RF electrode followed by immediate surgical resection. Resected specimens were examined by hematoxylin and eosin (H&E) staining and nicotinamide adenine dinucleotide (NADH) diaphorase staining to assess tumor viability.

Results All ablation procedures were performed successfully. For the 122 treated patients with solid tumor (≤ 2cm in diameter at 90° & 95°, ≤ 1.5cm in diameter at 85°, ≤ 1.0cm in diameter at 80°) nicotinamide adenine dinucleotide in its reduced form–diaphorase staining showed no evidence of viable cells. For the 108 treated patients with cystic tumor (≤ 1.0cm in diameter at 90° & 95°, ≤ 0.5cm in diameter at 80° & 85°) there was no evidence of viable malignant cells.

Conclusion RFA is a safe and promising minimally invasive treatment for solid tumor with diameter less than 2.0cm, while for cystic tumor with diameter less than 1.0cm at 90°. Because the thermal solidification range is larger than the damage area in cystic tumor, RFA is more suitable for solid tumor.

Key words breast tumor; ultrasound-guided; radiofrequency ablation.
Title: The oncologic safety of nipple-areolar complex skin sparing mastectomy compared with skin sparing mastectomy: 8 years follow up results

Kyung Jun Yeu¹, Jeong Yeong Park¹, Jung Eun Choi¹, Su Hwan Kang¹, Young Kyung Bae² and Soo Jung Lee¹. ¹Yeungnam University College of Medicine, Daegu, Korea and ²Yeungnam University College of Medicine, Daegu, Korea.

Body: Background: Skin sparing mastectomy (SSM) has been conducted in breast cancer patient because of both oncologic safety and cosmetic satisfaction. Preservation of nipple-areolar complex (NAC) is helpful to keep more natural breast shape, but, can cause anxiety about local recurrence. This study reviewed long term follow-up result of SSM and nipple-areolar skin sparing mastectomy (NASSM), retrospectively.

Patients and methods: This study included 272 primary breast cancer patients who received SSM (94 patients) or NASSM (178 patients) except bilateral breast cancer from September 1996 to December 2008. Frozen section was conducted for analysis of NAC resection margin status. In case of positive resection margin, NAC was sacrificed. Local recurrence and overall survival of SSM and NASSM group was analyzed.

Results: The mean follow-up was 94.9 months. 81 NAC resection margins (29.8%) were invaded by tumor cells. The positive resection margin of NAC was associated with presence of ductal carcinoma in situ (p=0.005), especially extensive intraductal component (p=0.005) and invasive carcinoma with multiplicity (p=0.048). The patients in NASSM group tended to have more worse disease free survival than those in SSM group (75.3% vs 86.2%, P=0.087). But, in analysis of only local recurrence including NAC, there were 25 cases (14.0%, 7 in skin flap and 18 in NAC) of local recurrence in NASSM group and 8 (8.5%) in SSM group. Local recurrence free survival of the NASSM group was 86.0% and that of the SSM group was 91.5% (P=0.278). Distant recurrence after surgical treatment for local relapse occurred in only one SSM case. There was no significant difference for the overall survival between NASSM and SSM group (97.8% vs 96.8%, p=0.556).

Conclusion: In this study, result of long term follow up showed that patients in NASSM group tend to have more local recurrence than patients in SSM group, even if there is no statistically significance. However, surgically well-controlled local recurrence of skin flap and/or NAC did not affect on overall survival. NASSM is alternative method for SSM with oncological safety and better cosmetic outcome.
Title: DCIS in low resource settings: The black swan of breast health care?

Miriam Mutebi¹, Lydia Cairncross¹, Eugenio Panieri¹ and Hannah Simonds¹. ¹Groote Schuur Hospital, University of Cape Town, Western Cape, South Africa.

Body: In situ carcinomas of the breast may constitute between 25-30% of all screen detected tumors in countries that practice routine screening. Of the in situ tumors, at least 80% are ductal carcinomas in situ (DCIS). In the United States, DCIS accounts for at least 25% of all newly diagnosed breast cancers. Presentations may vary in non screened populations.

Aim: To determine the clinical presentation and surgical management of patients presenting with isolated ductal carcinoma in situ at a single tertiary centre in the Western Cape, South Africa over a 5 year period. (Jan 2008-Dec 2012)

Secondary: To review the diagnostic techniques most commonly used.

Results:

42 patients with isolated DCIS were identified (41 females and 1 male) with an average age of 58 years. DCIS comprised less than 1% (42/3768) of all breast malignancies managed in this period. Most patients presented with a breast lump (23/42). 6 patients presented with nipple ulceration and 5 patients with a nipple discharge. 8 patients had their lesions picked on mammography. The diagnosis was made on core biopsy in 14 patients while 8 patients required excision of the palpable lump to make the diagnosis. 6 patients had a punch biopsy, 4 patients underwent a micro-ductectomy and 8 patients required a stereotactic biopsy. 2 patients had a diagnostic ROLL performed.

In terms of primary surgical management, 23 patients underwent a primary mastectomy, 6 patients had a WLE and 6 patients had a ROLL with therapeutic intent. 3 patients declined surgery and 1 was transferred to a different unit. 3 patients were poor surgical candidates and were placed on tamoxifen only. In terms of axillary management, 9 patients had a concurrent axillary clearance and 9 patients had a sentinel lymph node biopsy.

Of the 12 patients who had initial BCT (either ROLL or WLE), half required mastectomy for close or involved margins and 2 patients required re-excision of margins. 2 patients had an immediate reconstruction and 2 underwent a delayed reconstruction. All the axillary node clearances and sentinel lymph nodes were negative for metastatic disease.

Considerations: The spectrum of presentation of breast malignancies differs markedly in resource limited and unscreened populations. The commonest clinical presentation for DCIS was a breast lump and our incidence of isolated DCIS (1%) was much lower than that reported in international series. A number of patients with failed core biopsies required excision biopsies for diagnosis. ROLLS and stereotactic biopsies were also used to make a diagnosis, but the skills and equipment for this are frequently lacking in most regional centers. The inappropriately high axillary clearance rate for our patients could be explained by diagnostic concerns over concurrent invasive disease and the previously limited availability of sentinel lymph node biopsy facilities.

Conclusion: Though rare, the management of DCIS in this set up serves to highlight the challenges of diagnosing and managing breast malignancies in LMICs. Practical interventions like increasing health worker training in core biopsy methods, and in the use of supportive aids like ultrasound, alongside increasing human capacity in cancer diagnostics, could help to improve the management scope of cancers in LMICs.

**Title:** Cytology and histopathology evaluation of sub-nipple tissue during intraoperative and postoperative time to predict neoplastic involvement of the nipple in patients with breast carcinoma

Giuliano M Duarte¹, Maria Virginia Thomazin¹, André Oliveira¹, Fernando Tocchet¹, Luciana Moreira¹, Adriana Worschech¹ and Renato Z Torresan¹. ¹UNICAMP â–“ State University of Campinas, Campinas, SP, Brazil.

**Body:** Introduction: The analyses of sub nipple tissue (SNT) have been used by some surgeons to preserve or not the nipple in nipple sparing mastectomy for breast carcinoma. Therefore, the intraoperative study of SNT becomes an important tool. However, it is uncertain if the SNT evaluation can safely predict the nipple involvement for carcinoma. The aim of this study was to evaluate the accuracy, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) of intraoperative imprint cytology, intraoperative frozen section and postoperative paraffin histopathology of SNT to predict involvement of the nipple in women with breast carcinoma.

Methods: It was realized a prospective study with 38 consecutives breast carcinoma women (stage 0, I, II and III) underwent to mastectomy. It was excluded inflammatory carcinoma and clinical evident nipple involvement. After mastectomy, the nipple areolar complex were dissected in an approximate thickness of 5mm simulating nipple-sparing flap dissection. Then, the SNT were dissected and submitted to imprint citology and frozen section during intraoperative time. Subsequently, it were submitted to routine paraffin histopathology analysis. The nipple was examined separately by paraffin histopathology (considered the gold standard). We considered any atypical cells like positive findings in all exams (cytology, frozen and paraffin).

Results: The mean of patient’s age was 59 years, the mean of tumor size was 34 mm in clinical exam and 31mm in pathological exam. The clinical and mammographic means of distance from tumor to nipple were 23 and 34 mm, respectively. The imprint cytology frozen section and paraffin histopathology of SNT showed: sensitivity 42.9%, 42.9% and 57.1%; specificity 80.6%, 96.8% and 100%; accuracy 73.7%, 86.8% and 92.1%; PPV 33.3%, 75% and 100%; NPV 86.2%, 88.2% and 91.2%, respectively. When we associated both intraoperative exams (imprint cytology and frozen section), the specificity (80.6% x 100%, p=0.01) and accuracy (76.3% x 92.1%, p=0.02) were worse than postoperative exam. The false negative of postoperative analyses was 8.8%.

Conclusion: These preliminaries outcomes showed a moderate sensitivity and good specificity of three exams, the low false negative rate of postoperative paraffin exam. Our dates suggest that SNT evaluation is a good method to predict nipple involvement and possibly the postoperative evaluation (histopathology) is better than intraoperative evaluation (imprint cytology and frozen section).

Body: INTRODUCTION: The value of primary tumor resection in patients with metastatic breast cancer is a topic of ongoing debate. We aimed to analyze the trend and impact of primary tumor resection on survival over the last two decades using a national database. We hypothesized that there would be a decreasing utilization of primary tumor resection over time with an increase in disease specific survival.

METHODS: All patients with stage IV breast cancer at diagnosis between the years 1988 and 2011 were identified in the SEER database. Univariate and multivariate descriptive and survival analyses were performed.

RESULTS: A total of 41,601 patients with stage IV breast cancer were included in the study, 98.9% (41,162) were females and 1.1% were males. Forty percent underwent surgery. Table 1 summarizes the other significant differences in demographic and tumor-related characteristics of patients who did and did not receive PTR. Over the 23- year study period there was a statistically significant temporal trend of decreased primary tumor resection (62% of patients underwent PTR in 1988, 42.4% in 2000 and 27.7% in 2011). On univariate analysis, patients who underwent PTR had a greater median disease-specific survival (DSS), (34 vs. 18 months, p<0.0001). Younger age (p<0.0001), non-African American race (p<0.0001), lower T and N-stage (p<0.0001), positive hormone receptor status (p<0.0001), lower grade (p<0.0001), mucinous histology (p<0.0001), radiation therapy (p<0.0001), and surgery performed in the latter years (p<0.0001) were also associated with improved DSS. On multivariate analysis increasing age (p<0.0001), AA race (p=0.0001), higher T and N stage (p<0.0001), negative hormone receptor status (p<0.0001), higher grade (p<0.0001), no history of radiation therapy (p=0.002), and surgery in earlier years were associated with increased mortality (p<0.0001). Not undergoing PTR was independently associated with increased mortality, (p<0.0001).

CONCLUSIONS: Results from this retrospective study suggest a survival advantage in patients with stage IV breast cancer who undergo primary tumor resection. However, there has been a marked reduction in the number of patients undergoing surgery, most likely reflecting more focused patient selection. Ongoing randomized controlled trials will help address the impact of primary tumor surgery on survival of patients diagnosed with metastatic disease.

Title: Nipple sparing mastectomy: Risks of wound complication in the setting of neo-adjuvant or adjuvant chemotherapy and/or radiation therapy

Selyne Samuel\textsuperscript{1}, Rebecca Viscusi\textsuperscript{1}, Amy Waer\textsuperscript{1}, Victor Gonzalez\textsuperscript{1}, Pavani Chalasani\textsuperscript{1}, Craig Hurst\textsuperscript{1}, Ethan Larson\textsuperscript{1}, Robert Livingston\textsuperscript{1} and Michele Ley\textsuperscript{1}. \textsuperscript{1}University of Arizona, Tucson, AZ.

Body: Background: Surgical care of breast cancer has evolved significantly over the past 40 years. Nipple sparing mastectomy (NSM) and skin sparing mastectomy (SSM) have become an increasingly used surgical management for women with malignant breast disease. To date, there are limited recommendations about the role of NSM in patients receiving aggressive adjuvant therapy. The purpose of this investigation is to determine whether NSM in the setting of neo-adjuvant or adjuvant chemotherapy and/or radiation therapy increased the risks for wound complications.

Methods: A retrospective chart review of nipple sparing mastectomies at a single institution was performed from 2007 to 2014. Multiple data points including neo-adjuvant or adjuvant chemotherapy and/or radiation therapy, obesity, smoking history, and type of reconstructive surgery were examined in detail.

Results: We counted the procedures by breasts affected and identified 76 NSM in the time period which met criteria. Of the 76 NSMs, 27 breasts received neo-adjuvant(20) or adjuvant chemotherapy and/or radiation(7) therapy. 21 breasts in the NSM group developed wound complications including skin flap necrosis (5), total nipple necrosis and loss (11) hematoma (2) infection(2) and seroma(1). The complications were seen in 11 in the non adjuvant treated setting (14%) and 9 (33%) in the adjuvant therapy setting.

Conclusions: Nipple sparing mastectomy are emerging as safe and adequate options for the management of malignant breast disease. Our results show there is a significant risk of wound complication associated with neo-adjuvant and adjuvant chemotherapy and radiation therapy in the setting of nipple sparing mastectomy. We are pursuing the development of new surgical techniques and guidelines to reduce these risks in these high risk patients.
Title: Flap fixation reduces seroma in patients undergoing mastectomy: A significant implication for clinical practice

James Van Bastelaar1,2, Arianne Beckers1, Maarten Snoeij1 and Yvonne Vissers1,2. 1Atrium Medical Center, Heerlen, Limburg, Netherlands and 2Orbis Medical Center, Sittard, Limburg, Netherlands.

Body: Background
Seroma formation is a common complication following mastectomy for invasive breast cancer. Seroma formation can cause problems in wound healing and infection, thus leading to seroma aspirations and repeated visits to the out-patient clinic. The key to reducing seroma formations seems to partly lie in the obliteration of dead space. However, the techniques used to achieve this goal are subjects of much controversy and debate. Mastectomy flap fixation (FF) is achieved by reducing dead space volume using interrupted subcutaneous sutures. We hypothesized that obliteration of the dead space following mastectomy would significantly reduce seroma formation, resulting in fewer outpatient visits and seroma aspirations. This study, aiming to reduce seroma formation after mastectomy, is a retrospective study that compared conventional mastectomy with mastectomy and flap fixation.

Methods
All patients undergoing mastectomy due to invasive breast cancer were eligible for inclusion. From May 2012 – March 2013 all patients undergoing mastectomy in 2 hospitals were treated using flap fixation. The skin flaps were sutured on to the pectoral muscle using polyfilament absorbable sutures. The data was retrospectively analyzed and compared to a historical control group (HC) that was not treated using flap fixation (May 2011 – March 2012). In the HC group, only the skin was sutured. Closed suction drainage was applied to all patients in both groups.

Results
180 patients were included; 92 in the FF group and 88 in the HC group. There were no significant differences in patient demographics. 36% of patients developed seroma in the group that underwent flap fixation; 59% of patients developed seroma in the historical control group (P=0.002). Seroma aspiration was performed in 15% of patients in the flap fixation group as opposed to 43% of patients in the control group (P<0.001). Multivariate analysis showed that the effect of flap fixation varied with the extent of surgery: whereas flap fixation reduced seroma formation in patients undergoing simple mastectomy or mastectomy with sentinel node recovery, FF did not reduce seroma formation in patients undergoing mastectomy with axillary lymph node dissection (i.e. modified radical mastectomy; P=0.04 for interaction).

<td>0.04</td>
</tr>
</tbody>
</table>
Conclusion
Patients undergoing mastectomy flap fixation displayed a significant reduction in seroma formation and fewer patients were subjected to seroma aspiration. Patients undergoing flap fixation required fewer seroma aspirations. Flap fixation is an effective surgical technique in reducing dead space and therefore seroma formation in patients undergoing mastectomy for IBC.

Title: External dosimetry and in vivo measurements improve surgical comprehension of intraoperative radiotherapy using Intrabeam™

Pierre-François Dupré¹, Dounia Bouzid², Petra Miglierini¹, Olivier Pradier¹, Dimitris Visvikis², Julien Bert² and Nicolas Boussion².
¹Cancer Institut CHU, Brest, France and ²LaTIM INSERM UMR 1101 CHU Brest, Brest, France.

Body:

Background

IORT is an option for patients with limited access to radiotherapy or patients wishing to avoid the prolonged course of External Beam radiotherapy (EBRT). The recent 5-years results of the non inferiority trial TARGIT-A suggest that with a short follow-up the 5-years risk for local recurrence is greater for the IORT arm. Several options can be suggested to improve those results.

Objectives

We choose to enhance surgical comprehension of IORT with Intrabeam™ by performing in vivo measurements comparing to external dosimetry taking into account tissues heterogeneities using a preoperative CT scan.

Material and Methods

Nine patients enrolled in french randomised trial RIOP-InCA underwent Intrabeam™ procedure for breast cancer treatment. Each patient had a preoperative CT scan to simulate the treatment on a Monte Carlo platform using an x-ray source model; in order to calculate the dose actually delivered by the Intrabeam™ system which takes into account the tissues heterogeneities. In vivo measurements using thermoluminescent dosimeters are also performed to evaluate the dose to the skin. Comparisons are done between simulated and measured data. Relative depth dose curves are also compared.

Results

The median age was 68.3 years [58-87]. The mean maximal diameter of lumpectomy was 71.3 mm [50-125]. The median size was 10.8 mm [5-19] and the median margin status was 12.8 mm [2-32]. 2 patients had micro metastatic involvement of sentinel lymph node without axillary clearance. SBR score was 1 for 5 patients and 2 for 2 patients. All histological subtype were ductal, one patient presented associated DCIS. 6 patients presented luminal A phenotype, 2 luminal B and 1 luminal B with HER-2 neu over-expression. 2 patients received supplemental EBRT (HER-2 neu over expression and SLN micro metastatic involvement). 2 patients had adjuvant sequential chemotherapy and all had adjuvant ani-aromatase hormono-therapy.

In vivo measurements on the skin using TLDs gives a mean dose of 1.3 Gy ± 1.1 Gy [0.1-4.9 Gy] in comparison with external dosimetry which had a mean dose of 1.5 Gy ± 0.8 Gy [0.3-6.2 Gy] at the same positions. No patient received a dose superior to the prescription of 6 Gy. Relative depth dose curves give a mean deviation of +36.7% ± 24.8% and +50.6% ± 16.8% in the tangential and perpendicular axes respectively from the manufacturer. Using the shielding allow a reduction of the dose by 10 concerning the ribs.

Conclusions

Results about the dose as a function of depth show clearly that we cannot consider breast as equivalent to water at this energy and may taking in account breast density. It seems to be important to spread the skin correctly from the incision, to recover carefully the applicator and use the shielding in order to avoid secondary effects as skin necrosis and ribs failures.

Our X-ray source model allows to have realistic dose distribution which hepls in better surgical comprehension of IORT particularly in the set up of the applicator.
Immediate implant-based breast reconstruction following total skin-sparing mastectomy: Defining the risk of preoperative and postoperative radiation therapy on surgical outcomes

Anne Warren Peled¹, Frederick Wang¹, Robert D Foster¹, Rachel Lentz¹, Michael Alvarado¹, Cheryl A Ewing¹, Laura J Esserman¹, Barbara Fowble¹ and Hani Sbitany¹. ¹University of California, San Francisco, CA.

Body: Background
Radiation therapy is an increasingly common adjuvant treatment in breast cancer therapy. As total skin-sparing mastectomy (TSSM) and immediate reconstruction becomes more widely performed, further defining the risks of various treatment regimens on surgical and reconstructive outcomes after TSSM is important. In this study, we assess the effects of premastectomy and postmastectomy radiation therapy on outcomes following TSSM and immediate prosthetic reconstruction.

Methods
All patients undergoing TSSM and immediate tissue expander/implant reconstruction at our institution between 2006 and 2012 were identified from a prospectively maintained database. Cohort 1 included patients undergoing TSSM and reconstruction without any radiation. Cohort 2 included patients with a prior history of radiation before TSSM and reconstruction. Cohort 3 included patients undergoing radiation after TSSM and reconstruction. Complication rates were compared between cohorts.

Results
A total of 580 patients were identified undergoing 903 breast reconstructions following TSSM. Cohort 1 included 727 breasts, cohort 2 included 63 breasts, and cohort 3 included 113 breasts. Compared to patients without radiation, patients with prior radiation were more likely to develop severe infection (7.3% vs. 20.6%, p = 0.001), incisional breakdown (3.1% vs. 9.5%, p = 0.01), and expander/implant loss (5.1% vs. 20.6%, p < 0.0001). Similarly, patients with postmastectomy radiation had higher rates of severe infection (22.1%, p < 0.0001) and expander/implant loss (17.7%, p < 0.0001) compared to patients without radiation, though equivalent rates of incisional breakdown (6.1%, p = 0.57). All three cohorts showed similar low rates of partial or complete nipple-areolar complex necrosis (1.2% vs. 3.2% vs. 0%, respectively).

Conclusions
Both preoperative and postoperative radiation following TSSM and immediate prosthetic reconstruction result in higher, but acceptable, complication risks. Risks of infection and expander/implant loss in irradiated patients who have undergone TSSM are similar to those reported after skin-sparing mastectomy. Further, the low rates of complications related to nipple-areolar complex skin preservation in irradiated patients are equivalent to those seen in non-irradiated patients, supporting the safety of performing TSSM in patients who require radiation therapy.
Title: Complications of breast reconstruction in a provincial population of breast cancer survivors

Elaine S Wai¹,³, Ling Hong Lu², Cheryl Alexander¹, Mary L Lesperance², Mary L McBride¹,³, Scott Tyldesley¹,³ and Chris Taylor³. ¹BC Cancer Agency â–“ Vancouver Island Centre, Victoria, BC, Canada; ²University of Victoria, Victoria, BC, Canada and ³University of British Columbia, Vancouver, BC, Canada.

Body: Background: Breast cancer is the most prevalent cancer in women in Canada. There are varying reports of the use of breast reconstruction in various populations and very few prospective trials or population reports of complications related to breast reconstruction in breast cancer patients. The goal of this study is to describe the use of breast reconstruction in breast cancer survivors in British Columbia, the risk of complications after breast reconstruction, and factors associated with a higher risk of complications.

Methods: Electronic Records from the BC Cancer Agency were used to identify women diagnosed with invasive breast cancer between 2001-2008 in British Columbia. Administrative hospital records used with permission of the British Columbia Ministry of Health, obtained through PopulationData BC, were used to obtain details about all surgeries, hospital admissions and associated complications for the cohort. Analyses of reconstruction for those treated with breast-conserving surgery (BCS) versus mastectomy were done separately. For those who underwent mastectomy following BCS, complications after BCS before mastectomy were attributed to the BCS, and those that occurred after mastectomy were attributed to the mastectomy. These analyses included a description of the type of reconstruction procedures used in this era, and the frequency and types of complications after the reconstruction procedures. Logistic regression was used to identify risk factors for complications post reconstruction.

Results: The cohort consisted of 18,642 women; 4868 had mastectomy alone, 8633 had BCS alone, 2894 had both, and 2247 had neither surgery. Of those undergoing BCS (11527), 746 had reconstructive procedures. Most of these were separate procedures; 55% were ≤50 years of age. The most common complication was "miscellaneous complication of internal prosthetic devices, implants or grafts". One hundred eighty (14%) of those with reconstruction after BCS had complications within 30 days of the reconstruction procedure, 134 (18%) had complications within one year of the procedure.

Of those undergoing mastectomy (7762), 7497 had their mastectomies within 1 year of diagnosis. Ninety-six had bilateral mastectomies. 1766 underwent reconstructive procedures; 74% were immediate procedures, 57% were ≤ 50 years of age. The most common complication was "miscellaneous complication of internal prosthetic devices, implants or grafts". One hundred sixty-seven (9%) of those with reconstruction after (or with) mastectomy had complications within 30 days of the reconstruction procedure, 227 (13%) had complications within one year of the procedure. Regression analysis showed that no radiotherapy (OR=0.65) and premenopausal status (OR=0.70) were significantly associated with a lower risk of complication post reconstruction.

Conclusion: Complications related to reconstructive procedures for breast cancer happened in the minority of breast cancer survivors. They were more common in those with BCS, and were more likely for those who underwent adjuvant radiotherapy or were postmenopausal.

Title: Mastectomy without drains: Flap adhesion and closure of dead space using TissuGlu® vs standard wound closure (SWC) - a parallel cohort comparison

Stefan Paepke1. 1Klinikum rechts der Isar der Technischen Universität München, Frauenklinik, Munich, Bavaria, Germany.

Body: Background: Mastectomy(ME) remains associated with high rates of minor complications and occasional revision surgery for wound healing/seroma. Closed suction drain use in an effort to reduce seroma related complications is the current standard procedure but drain efficacy has been contested in multiple reports. Mechanical closure of dead space with suturing techniques has been shown to be effective but this is often not practical in these patients and increases operating time. Fibrin sealants may reduce early drainage volume but have not been shown to allow elimination of drains. Recent reports have shown that closure of dead space can be achieved through the use of a new resorbable surgical adhesive (TissuGlu®, Cohera Medical, Pittsburgh) allowing for the elimination of drain use in that procedure. Our work with this adhesive began in 2013, with use initially limited to revisions and patients at high risk of postoperative complications; later extended use to ME in the general patient population without drain placement. Here we present the results of our prospective observation of postoperative outcomes in this early series.

Materials & Methods: A parallel cohort comparison was performed for non-inferiority of TG/No Drains vs. SWC with respect to postoperative fluid management and seroma related complications. All primary ME +/- SLNB and/or ALND were prospectively documented for operative procedure variables and outcomes, including male patients and bilateral cases. 56 MEs patients (66 MEs) from Feb 2013 through Feb 2014 were documented and analyzed. Total drained volume, aspirations, minor wound healing complications and need for revision surgery were compared.

Results: Patient demographics and procedure variables were comparable in the two groups.

**Discussion/Conclusions**: Our experience suggests a clear advantage in the TG/no-drain approach in mastectomy. In addition to the improved patient comfort and earlier discharge with TG, patients with drains had significantly higher total fluid collection and still required more aspirations on average than the test group. Non-inferiority for minor complications was not only achieved, but there seems to be a trend toward reduced complications in the no drain cohort. A prospective, randomized study is planned to verify our initial impressions.
Title: Is the combination of fat grafts and platelet rich plasma effective and safe? An experimental study in rats

Ruffo Freitas-Junior¹, Alexandre R Blumenschein¹, Marise AR Moreira¹, Maria-Auxiliadora PC Cysneiros¹ and Roseana N Pereira¹. ¹Federal University of Goias (UFG), Goiania, Goias, Brazil.

Body: Autologous fat grafts and lipofilling can be used for breast reconstruction after breast conserving therapy. Fat is considered an ideal filler because of its low cost, ease of harvest, abundance in the human body and low immunogenic and allergic reaction due to its autologous nature. Platelet rich plasma (PRP) is a plasma fraction, with platelet count above baseline, generally obtained via centrifugation of blood. PRP theoretically promotes tissue regeneration due to fact that it concentrates a greater amount of growth factors essential in the process of tissue regeneration and neovascularization. This paper aims to examine if the association of fat grafts and PRP improves graft viability in female rats, through an experimental, randomized and blinded study, which involved 47 animals. These animals underwent fat graft harvest from their inguinal fat deposits and fat grafting subcutaneously to their cranial region. In 22 animals the fat graft was mixed with PRP and in 25 the fat was grafted by itself. After a 100 day period, the animals were sacrificed and the fat grafts were analyzed using scores from 0 (absent) to 4 (abundant), in optical microscopy by two independent and blinded pathologists, by means of the following variables: fat graft cell viability, fat necrosis, tissue inflammation and fibrosis. Regarding fat graft cell viability, the PRP group scored moderate/abundant in 63% of the cases and the fat graft only group scored absent/slight in 72% of the cases (p<0.05). The PRP group presented lower fat necrosis scores and lower tissue inflammation scores when compared to the fat graft only group (p<0.05). The presence of tissue fibrosis was rarely observed in both groups. Tumors (dermoid cysts) within the fat grafts were observed in 3 animals in which the grafts were mixed with PRP. It is concluded that PRP improves the viability and integration of fat grafts in rats, but more studies are needed to fully understand the exact mechanisms that lead to this improvement and assess the safety of the method for use in humans.
Title: Prediction of local recurrence following mastectomy

Sarah Al-Himdani, Simon Timbrell, Kian Tan, Julie Morris and Nigel Bundred. 'University Hospital of South Manchester NHS Foundation Trust, Manchester, United Kingdom.

Body: Background: Rates of local recurrence following mastectomy vary considerably in the literature, ranging from 1.7% to 11.5%. Previous studies have attempted to identify risk factors for recurrence and whether these relate to aggressive disease or to inadequate local treatment. We aimed to identify local recurrence rates at our institution to determine risk factors associated with local recurrence.

Methods and materials: A retrospective study of all women undergoing mastectomies for unilateral T1-T3 breast cancer between 2000-2005 was undertaken. Kaplan-Meier curves were created and the log-rank test calculated to assess for differences between groups. The incidence of local, regional and systemic recurrence was identified at 5 and 8 years post-mastectomy. Incomplete excision/margin involvement was defined as margins 1mm or less. Demographic, biological and treatment-related factors associated were used to identify predictors of local recurrence.

Results: In total, 581 women were studied (mean age: 59; range: 22-96); 462 simple mastectomies (SM) and 106 skin-sparing mastectomies (SSM) which included 199 (34%) screen-detected and 382 (66%) symptomatic cancers. Mean follow up was 6.7 years (range: 5-12.4) and longest was 12.4 years. SSM patients had a lower mean age (p=<0.001), with a smaller tumour size (p=0.022), fewer positive lymph nodes (p=<0.001) and less co-existing ductal carcinoma in situ (DCIS) (p=<0.001) than SM patients. Recurrence rates for SM were 5.6% and 6.9% and for SSM, recurrence rates were 5.7% and 9.0% at 5 and 8 years respectively. Recurrence in node negative patients was 2.2% at 5 years. Predictors of local recurrence were node positivity (HR 8.03; 95% CI 3.2-20) and margin involvement/close margins (HR 3.34; 1.64-6.8).

Conclusion: No significant difference between recurrence rates in SSM and SSM groups was identified. The presence of over four positive lymph nodes and incomplete excision margins indicates an increased risk of recurrence and in these patients, immediate SSM reconstruction should be considered prudently.
Title: A systematic review of the clinical evidence regarding PIP breast implants

Umar Wazir¹, Abdul Kasem¹ and Kefah Mokbel¹. ¹London Breast Institute, Princess Grace Hospital, London, United Kingdom.

Body: Background: Mammary implants marketed by Poly Implant Prothèse (PIP) were found to contain industrial grade silicone and this caused heightened anxiety and extensive publicity regarding their safety in humans. These implants were used in a large number of patients worldwide for augmentation or breast reconstruction.

Methods: Articles were identified by searches of Medline, PubMed, Embase and Google Scholar databases up to March 2014 using the terms: "PIP", "Poly Implant Prothèse","breast implants" and "augmentation mammoplasty" or "silicone" In addition the websites of regulating bodies in Europe, USA and Australia were searched for reports related to PIP mammary implants.

Results: PIP mammary implants are more likely to rupture than other implants and can cause adverse effects in the short to the medium term related to the symptoms of rupture such as pain, lumps in the breast and axilla and anxiety. Based on peer-reviewed published studies we have calculated an overall rupture rate of 14.5% (383/2635) for PIP implants.

Conclusions: There is no evidence that PIP implant rupture causes long-term adverse health effects in humans so far. The long-term adverse effects usually arise from inappropriate extensive surgery, such as axillary lymph node dissection or extensive resection of breast tissue due to silicone leakage.
Body: Purpose: Immediate implant-based breast reconstruction followed by postmastectomy radiation therapy (PMRT) is controversial because of the risk of compromised treatment plans, particularly left-sided plans including internal mammary nodes (IMNs) as target. Using direct-to-implant reconstruction with anatomical implants may improve plans due to their unique shape over the chest wall. This single-institution study evaluated the effects of immediate breast reconstruction with anatomical implants on the quality of PMRT delivered by 3-dimensional conformal radiation therapy (3D-CRT).

Methods and Materials: Patients undergoing immediate direct-to-implant reconstruction with anatomic implant, performed by a single surgeon, were treated between 2008 and 2013. For each patient, 2 plans were created and calculated, including or excluding IMNs. No electron fields were used. The primary endpoint was the dose distribution among reconstructed breast (RB), heart, lungs and IMNs and between right and left breasts. Six patients were treated with the Varian RPM system for left sided BC due to anterior heart position.

Results: Of 29 consecutive patients, 11 received right-sided and 18 received left-sided PMRT. For plans excluding IMNs, mean Dmean was 49.09 Gy (98.2% of the prescribed dose) for right and 48.51 Gy (97.0%) for left RBs. For plans including IMNs, mean Dmean was 49.15 Gy (98.3%) for right and 48.46 Gy (96.9%) for left RBs. Mean RB D95 ranged from 42.05 Gy (left side with IMNs) to 45.15 Gy (right side with IMNs). Mean IMN Dmean was almost identical for left- and right-sided treatment (47.89 Gy and 47.27 Gy, respectively; \( P=.340 \)). Heart doses were very low, with mean Dmean values of 1.25 Gy (range, 0.83-1.46) and 1.56 Gy (range, 1.23-2.10) for left-sided plans excluding and including IMNs, respectively (\( P<.001 \)). Mean lung V20 values ranged from 13.80% for left-sided treatment excluding IMNs to 19.47% for right-sided treatment including IMNs.

Conclusion: PMRT can be delivered effectively and safely by 3D-CRT after direct-to-implant breast reconstruction with anatomical implants. The reconstructed breast and the IM chain coverage were excellent and the heart dose was very low, (probably due to the use of the RPM system). Lungs V20 was comparable with other publication. Our study support the hypothesis that immediate breast reconstruction per se is not an impediment to the delivery of high-quality PMRT by modern 3D-CRT technology. Based on our findings, reconstructive surgeons should consider the use of anatomical implants for immediate breast reconstruction in patients requiring subsequent PMRT.
Title: Variation in UK reconstructive practice in the face of post-mastectomy radiotherapy

James R Harvey, Nigel J Bundred, Cliona C Kirwan, Ashu Gandhi and Paula J Duxbury. 1Manchester Academic Health Sciences Centre, University of Manchester, Manchester, United Kingdom and 2Nightingale Centre, UHSM, Manchester, United Kingdom.

Body: Approximately 30-40% of women are not offered immediate breast reconstruction because the possibility of post-mastectomy radiotherapy (PMRT) is unknown at the time of mastectomy. Breast reconstruction may be delayed until final pathology is available and need for radiotherapy established. Surgical literature is replete with studies of varying quality, reporting complication rates for a range of reconstructive procedures, highlighting the need for surgical trials of reconstructive techniques in women at risk of PMRT. Decisions for these patients are complex, involving multiple clinicians including surgeons and oncologists. To inform a surgical trial design, we aimed to determine current UK surgical practice and gain an understanding of the drivers behind decision-making.

Methods: A questionnaire, validated in a pilot population, was posted to Consultant members of the Association of Breast Surgery (UK). We collected data on current practice in conducting Delayed, Immediate and Delayed-immediate reconstructive surgery. We collated data on type and volume of procedure performed and factors affecting decision-making including delay to adjuvant treatment, risk of complications, perception of patients' quality of life (QoL) and aesthetic satisfaction.

Results: Of 355 surgeons, 130(37%) responded. Of these, 77% felt the current evidence base was not adequate to guide surgical decisions and 80% felt a need for further trials to guide best treatment. Despite a lack of scientific evidence demonstrating a difference in cosmesis or QoL between Immediate and Delayed reconstruction, 85% felt there is not equivalent cosmesis and 71% felt there is not equivalent QoL between the two groups. There is considerable heterogeneity in reconstructive approach to patients at risk of PMRT (Table 1). Delayed reconstruction remains the most popular option, being regularly used by 94% of surgeons despite only 34% of surgeons believing the majority of patients are satisfied with the approach. Significantly fewer surgeons perform Immediate implant based reconstruction (with or without ADM) than Delayed (p<0.01). Implant reconstruction is performed by 71% of surgeons in patients at risk of PMRT, but only 44% of surgeons felt patients were happy with the final results.

The three most important drivers in making a reconstructive choice were 1. Effect of PMRT on the cosmetic result 2. Minimising risk of complications and avoiding delay to adjuvant treatment 3. Pre-operative uncertainty over the need for PMRT.

Conclusions: Surgeons employ a variety of approaches to reconstruction in the face of PMRT, the most common approach being delayed reconstruction. Decision-making is based upon individual surgeon’s perception of risks including likely delay to adjuvant therapy and effect of PMRT on the reconstruction. Drivers appeared to be more surgeon-centred rather than patient-based. There is awareness of a lack of evidence to support decision-making and the need for high quality studies. Randomised clinical trials are needed to provide an evidence base for outcomes.
Title: Technical results and complication rates after nipple-sparing mastectomy and direct-to-implant breast reconstruction using porcine acellular dermal matrix for implant coverage

Roland Reitsamer¹ and Florentia Peintinger¹. ¹University Hosptial Salzburg, Breast Center Salzburg, Paracelsus Medical University, Salzburg, Austria.

Body: Objective:
To evaluate the feasibility and complication rates of nipple-sparing mastectomy (NSM) and direct-to-implant breast reconstruction using a porcine acellular dermal matrix (ADM) for implant coverage.

Methods:
NSM and direct-to-implant breast reconstruction using a porcine ADM for implant coverage was performed in a series of 91 breasts in 63 patients. Technical results, complications, and cosmetic results were collected from patient records.

Results:
Short-term complications within one month comprised minor complications as minimal nipple necrosis in 13.2%, and infection in 1.1%. Major complications, as hemorrhage with surgical evacuation in 4.4%, and implant loss due to skin breakdown in 4.4%, totaled in 8.8%. Within three months after primary surgery 3 further severe complications with reoperation occurred. In 87.9% no second surgical intervention was necessary and cosmetic results were good or excellent. After a mean follow-up of 12 months (range 5 - 35 months) no further complications could be observed. Patient satisfaction was high for 92.3% of the patients and subjective cosmetic result was excellent in 90.1% and satisfactory in 2.2%.

Conclusion:
Direct-to-implant breast reconstruction using a porcine ADM for implant coverage after NSM is an innovative approach resulting in a high patient satisfaction. The technique is challenging but feasible and complication rates are acceptably low.
Title: Antibiotic prophylaxis in prosthesis-based mammoplasty: A systematic review

Naisi Huang¹,², Mengying Liu¹,² and Jiong Wu¹,². ¹Shanghai Cancer Center, Fudan University, Shanghai, China and ²Shanghai Medical College, Fudan University, Shanghai, China.

Body: Background Implants are used in over two-thirds of breast reconstructions and all aesthetic augmentations. Although considered as an aseptic surgery, infection rate after prosthesis-based breast surgery is reported to be 2% to 2.5% of patients and represents the leading cause of morbidity after reconstructive and aesthetic surgery. Therefore, prophylactic antibiotics is supported by several studies to prevent surgical site infection (SSI) and capsular contracture (CC). However, there is no high quality evidence on antibiotic prophylaxis in prosthesis-based mammoplasty.

Methods An electronic search was conducted in Medline, Embase, and Cochrane. Studies of prosthesis-based breast surgery with control group and antibiotic prophylaxis were included. Two authors independently screened, assessed and then extracted information from the included studies. Mantel-Haenszel method was used to conduct meta-analysis. All analysis was performed by STATA 12.0. Studies that were not qualified to be included into meta-analysis were summarized and described.

Results 15 studies were included into analysis. Average Jaded score for RCT studies was 2.5 (1-4). Average Newcastle score for non RCT studies was 7.55 (4-9). 3 studies compared systematic antibiotic prophylaxis with no antibiotic use, while no significant difference was observed. Compared with antibiotic prophylaxis within 24 hours, extended systematic antibiotic prophylaxis more than 24 hours postoperatively could significantly reduce infection rate (RR=0.638, CI 0.453-0.898). The average SSI rate was 4.6% in extended antibiotic group versus 11.1% in control group. 15.38 patients needed to be treated to prevent 1 case of SSI. However, in subgroup analysis, extended antibiotic prophylaxis could significantly decrease SSI rate in implant reconstruction surgery (RR=0.508, CI 0.349-0.739), but not in aesthetic breast surgery (RR=1.458, CI 0.602-3.528). Topical antibiotic irrigation could reduce CC rate (RR=0.472, CI 0.316-0.707), while might not be able to reduce infection rate. The average CC rate was 4.86% in topical antibiotic prophylaxis group, versus 6.81% in control group. 51.28 patients needed to be treated to prevent 1 case of Baker grade III or IV CC. Cephalosporins were the most commonly preferred antibiotic regimen in included studies. Nevertheless, there was no consensus of antibiotic prophylaxis combination or timing.

Conclusions Extended systematic antibiotic prophylaxis will significantly reduce SSI rate, especially in implant breast reconstruction. Topical antibiotic irrigation would decrease CC rate, while might not be able to reduce infection rate. Cephalosporins are generally recommended as antibiotic prophylactic regimen which cover the most commonly identified implant–associated bacteria. Risk factors such as chest irradiation and diabetes should be take into consideration when prescribing antibiotic prophylaxis. More better-designed RCTs are awaited to demonstrate the proper antibiotic regimen in prosthesis-based breast surgery to reduce complications.
Title: Integrated immunologic assessment of tumor infiltrating lymphocytes (TILs) and peripheral blood to assess synergy of cryoablation (cryo) plus ipilimumab (ipi) in early stage breast cancer (ESBC) patients (pts)

Body: Background: In pts with ESBC, cryo combined with cytotoxic T-lymphocyte antigen 4 blockade was well tolerated and did not delay standard-of-care mastectomy. As observed in mice, cryo+ipi may liberate tumor-associated antigens, synergistically activate tumor-reactive T-cells, and confer long-term anti-tumor immunity. Because singular biomarkers of response to immunotherapy have not been well defined, we conducted an integrated immunologic assessment to explore potential predictors of immune activation and response.

Methods: Serial blood and pre-/post-treatment tumor tissue were collected from 18 pts treated with cryo (6 pts), single-dose ipi at 10mg/kg (6 pts), or cryo + ipi (6 pts). A Meso Scale Discovery platform was used to measure plasma cytokine interferon gamma (IFNγ). Multiparameter flow cytometry was used to evaluate peripheral and intratumoral T-cell and myeloid cell quantity, T-cell phenotype (effector versus regulatory), proliferation state (Ki67), and activation state (inducible costimulator [ICOS] expression). Finally, a DNA deep sequencing platform was used to conduct T-cell repertoire analysis of peripheral T-cells and TILs.

Results: Sustained >2-fold elevations (1 month post-treatment) in plasma IFNγ were observed in the majority (4/6) of pts receiving cryo/ipi (median 6-fold increase), but in the minority of pts receiving cryo (0/6, median 0-fold) or ipi (2/6, median 0-fold). Similarly, sustained >2 fold elevations in ICOS expression in peripheral CD3+CD4+ T-cells, a known pharmacodynamic marker of ipi, were observed in the majority (5/6) of pts receiving cryo/ipi (median 4-fold increase), but in the minority of pts receiving cryo (0/6, median 0-fold) or ipi (2/6 ipi; median 1-fold). No trends were observed in peripheral myeloid derived suppressor cells. Analysis of TILs by flow cytometry identified increased numbers of proliferating CD8+ T-cells (CD8+Ki67+) in ipi and cryo/ipi groups relative to cryo alone; furthermore, the ratio of proliferating (CD8+Ki67+) to regulatory (CD4+CD25+FoxP3+) cells was enhanced in the cryo/ipi group. Finally, analysis of T-cell repertoire in TILs demonstrated that cryo/ipi generated an influx of novel T-cell clones, with select clones surging dramatically in predominance and circulating within the periphery.

Conclusions: Utilizing an integrated assessment, we identified evidence of immunologic synergy with combination cryo/ipi versus either therapy alone. Of the tested parameters, peripheral CD4+ ICOS expression, plasma IFNγ, Ki67-gated TIL effector/regulatory ratios, and clonal repertoire analysis were identified as promising biomarkers of immune activation. These findings will inform a prospective assessment of potential immunologic biomarkers of immune response and clinical benefit in a phase 2 study of cryo-immunotherapy in ESBC.

Title: HER2 discordant results in local vs. central testing in the phase 3 nelipepimut-S trial and implementation of Leica Bond Oracle HER2 Immunohistochemistry (IHC) System for low and intermediate levels (1+, 2+) of HER2 protein expression as a companion diagnostic

Michelle Melisko¹, Elizabeth A Mittendorf², Sufia Safina³, Michael Schenker⁴, Murray A Brunt⁵, Maria Litwiniuk⁶, John Mackey⁷, Katarina Petrakova⁸, Svitlana Alieva⁹, Lacey Chance¹⁰, Gavin S Choy¹⁰, Mark Ahn¹⁰, Adamm Hamm¹¹, Sonia Kumar¹² and Hope S Rugo¹. ¹University of California, San Francisco, CA; ²U.T. MD Anderson Cancer Center, Houston, TX; ³Republican Clinical Oncology Center, Kazan, Republic of Tatarstan, Russian Federation; ⁴Sf Nectarie Oncology Center, Craiova, Romania; ⁵University Hospital of North Staffordshire, Stoke on Trent, United Kingdom; ⁶Greater Poland Cancer Center, Poznan, Poland; ⁷Cross Cancer Institute, Edmonton, AB, Canada; ⁸Masaryk Memorial Cancer Institute, Cancer Care Clinic, Brno, Czech Republic; ⁹Donetsk Regional Antitumor Center, Donetsk, Ukraine; ¹⁰Galena Biopharma, Inc, Portland, OR; ¹¹Aptiv Solutions, Durham, NC and ¹²Leica Biosystems, Danvers, MA.

Body: Background: The distinction between HER2-positive (IHC 3+ or 2+ with FISH ratio >/= 2) and not overexpressing HER2 has been the focus of many diagnostic tests over the past years in association with development of HER2-targeted therapies. The paucity of therapies developed for the low to intermediate HER2 protein expression populations has resulted in limited attention to their diagnostic precision and accuracy. The development of NeuVax™ (nelipepimut-S; Galena Biopharma, Inc.) in the defined population requires a HER2 IHC 1+/2+ diagnostic that precisely and accurately ensures identification of targeted patients. We describe discordance rates between local and central testing performed to identify tumors with HER2 IHC 1+ or 2+ expression that supports the development of a method to validate HER2 1+ and 2+ (FISH < 2.2) patients who receive nelipepimut-S adjuvant therapy.

Methods: The Prevention of Recurrence in Early Stage, Node-Positive Breast Cancer with Low to Intermediate HER2 Expression with NeuVax™ Treatment (PRESENT) study, is a multicenter, multinational, prospective, randomized, double-blind, controlled Phase 3 study assessing efficacy and safety of the peptide vaccine nelipepimut-S, in HLA A2 or A3 positive patients with early stage, node positive breast cancer expressing low and intermediate levels (IHC 1+/2+) of HER2 protein. PRESENT 2-step screening includes HLA testing and central lab confirmation of HER2 1+ or 2+ expression using the DAKO HercepTest.

Results: As of 2 June 2014, 1454 patients underwent central IHC testing for HER2 and had a quantifiable result of 0, 1+, 2+, or 3+ for both local and central test. Per local testing, 61% (HER2 1+, n=612; HER2 2+, n=275) were eligible and 39% (HER2 0, n=468; HER2 3+, n=99) were ineligible. Of those eligible by local testing, 67.5% (n=599) were confirmed as eligible per central testing for a discordance rate of 32.5% (n=288). Of the 288 discordant samples tested centrally, 73.6% (n=212) and 26.4% (n=76) were reported as HER2 0 and 3+, respectively. 8.7% (76/877) of patients found to be HER2 1+ or 2+ by local testing were determined to be HER2+ (IHC3+) by central testing.

Conclusions: Current tests for HER2 expression are defined by their ability to determine 3+ positivity, yet significant discordance still occurs with nearly 9% false negative rate in this trial. Similarly, marked discordance exists between local and central laboratory test results for HER2 by IHC at 1+/2+ levels of expression. The relatively high discordance rate observed may be due, in part, to the lack of a validated IHC assay for low-to-intermediate expression of HER2 (0, 1+, and 2+). In order to improve accuracy of testing and to develop a companion diagnostic for nelipepimut-S, the Leica Bond Oracle HER2 IHC System has been validated to determine samples across the IHC spectrum (0, 1+, 2+ and 3+) and is now incorporated into HER2 screening for the PRESENT trial as a companion diagnostic to increase accuracy, precision, and specificity in discerning HER2 1+ and 2+ patients.
Title: A Phase Ib Study of an adjuvant GM-CSF-Secreting Breast Cancer Vaccine

Karen S Anderson¹, Beth Overmoyer², Christine Canning², Jennifer Savoie², Garrick Wallstrom¹, Eric P Winer² and Glenn Dranoff². ¹Biodesign Institute, Tempe, AZ and ²Dana-Farber Cancer Institute, Boston, MA.

Body: Background: Vaccination with tumor cells engineered to secrete granulocyte-macrophage colony stimulating factor (GM-CSF) generates potent, specific, and long-lasting anti-tumor immunity in multiple tumor models. Here, we present analysis on the safety, feasibility, and biologic activity of an autologous GM-CSF-secreting breast cancer vaccine in the high-risk adjuvant setting.

Methods: Following IRB approval and patient consent, 18 patients with stage II-III breast cancer underwent tumor procurement for vaccine development at the time of breast surgery. Patients were required to have at least 4 cm of primary tumor, or have received neoadjuvant chemotherapy with at least 2 cm of residual tumor. 11 patients had insufficient tumor following neoadjuvant chemotherapy. 7 patients had sufficient tumor harvested to produce and subsequently receive vaccine therapy. Breast cancer cells were transduced with a replication defective adenoviral vector encoding GM-CSF and irradiated. Vaccinations were started 4-12 weeks after completion of all chemotherapy, immunotherapy, and radiation therapy. Vaccines were delivered subcutaneously (sc) and intradermally (id) weekly for three weeks, then every other week for a total of 6 doses. Immune monitoring included skin biopsies of vaccine sites, measurement of leukocyte populations, and proteomic-based assessment of antibody responses.

Results: Tumor cell yields ranged from 0.07-31.6 x 10⁶ cells. Dose levels were based on cellular yield, ranging from 10⁵- 4 x10⁶ cells/dose for the 7 patients with sufficient cell numbers. Vaccinated patients were 32-65 years of age, and all received 6 vaccines total. Three patients developed relapse within one year of the start of vaccinations, one of whom died at 14 months. The remaining four patients remained disease-free 23-34 months from start of vaccine. Toxicities related to treatment were mild and included Grade I/II local injection-site reactions, as well as grade I/II fatigue, fever, upper respiratory symptoms, cough, and joint pain. One episode of grade 3 fatigue was observed. Increases in antibody responses (p < .05) were observed for 17 antigens in at least 4 out of 5 patients evaluated.

Conclusion: For larger tumors, breast cancer cells can be harvested from a subset of patients in sufficient number for autologous vaccine production at the time of breast surgery. Autologous vaccination can induce immune responses with limited toxicity. The proteomic-based identification of antigen-specific immune responses following vaccination will be presented.
Title: A phase 1/2 study of Ad.p53 DC vaccine with indoximod immunotherapy in metastatic breast cancer

Hatem H Soliman1, Susan E Minton1, Roohi Ismail-Khan1, Hyo S Han1, Nicholas N Vahanian2, Charles J Link2, Gene Kennedy2, Howard Streicher3, Daniel Sullivan1 and Scott J Antonia1. 1Moffitt Cancer Center, Tampa, FL; 2NewLink Genetics Inc, Ames, IA and 3National Cancer Institute, Bethesda, MA.

Body: Background: Indoleamine 2,3 dioxygenase (IDO) is a tryptophan-catabolizing enzyme that causes immunosuppression in the tumor microenvironment. Indoximod is an IDO pathway inhibitor. Preclinical data suggests indoximod enhances the activity of dendritic cell (DC) vaccines. Ad.p53 is an adenovirus used to generate autologous dendritic cell (DC) vaccines against p53 epitopes. We initiated a phase 1/2a trial of indoximod + Ad.p53DC to explore the safety and efficacy of the combination along with response to subsequent chemo. The phase 1 safety data were previously presented and the treatment was well tolerated with no DLTs. (Soliman, ASCO 2013) This abstract includes new phase 2a safety/efficacy data and updated outcomes on all phase 1/2 metastatic breast cancer patients who received Adp53DC+indoximod and any subsequent response to salvage chemo.

Methods: The phase 2a study combined indoximod 1600mg PO BID with up to 6 Ad.p53 DC vaccinations q2wks. The trial used a single arm, Simon two stage design (n=12 in 1st stage, 25 in 2nd stage) with objective response as the primary endpoint. One response out of 12 was required for progression into second stage. The study had 90% power to detect 20% response rate with a p=.09. Patients with measurable, metastatic breast cancer, <3 lines of chemo in metastatic setting, p53 IHC >5%, ECOG 0-2, no autoimmune disease were eligible. Study treatment continued until disease progression or unacceptably toxicity.

Results: Twelve phase 2 patients were accrued, 9 (7 TNBC, 2 ER+/HER2-) received ≥1 dose of Ad.p53DC+indoximod (3 did not due to rapid disease progression during vaccine preparation). Six patients had ≥1 prior line of chemo. Seven (58%) subjects experienced any grade AE, there were no treatment related AEs ≥G3. All treatment attributable AEs were G1-2, <10% frequency, and included anemia, nausea, lymphopenia, photophobia, and headache. All discontinuations were due to disease progression. Best response to immunotherapy in phase 2=1 SD, 8 PD. Phase 2 median TTP = 6.85 wks (3.8-18.1), OS = 18.1 wks (3.8-52) with 3 patients alive as of June 2014. Five patients who received ≥2 cycles of chemotherapy after immunotherapy demonstrated 1 PR, 3 PD, 1 pending scan. For the entire phase 1/2 breast cohort (21 in phase 1, 9 in phase 2) the median TTP = 9.85 weeks (3.8-22.1), OS=38.7 (3.8-122.1) weeks, with 1 patient from the phase 1 cohort alive as of June 2014. Ten out of 21 evaluable patients (1 CR, 7 PR, 2 SD, 11 PD) had clinical benefit from chemotherapy after immunotherapy (9 patients had rapid decline and did not get one full cycle of therapy). All but one of the responders had seen prior chemotherapy in the metastatic setting (including a CR after 4 prior lines of chemo). Median OS in the chemo responders was 69.4 wks (30.1-122.1).

Conclusions: Indoximod+Ad.p53DC was well tolerated. Across phase 1/2 the best response to immunotherapy alone was SD in 4 pts while 10 of 21 (47%) (including 1 CR) responded to subsequent chemotherapy in this largely pretreated cohort. There may be a chemosensitization effect of indoximod+Ad.p53DC. Future trials should combine this treatment with chemotherapy in appropriately selected patients.
**Title:** Discovery of fully human monoclonal antibodies as therapeutic candidates for the treatment of HER2-negative breast cancer

Christy Boozer¹, Paul Algate¹, Aurelio Bonavia¹, Mark Branum¹, Po-Ying Chan-Hui¹, Alison Fitch¹, Brad Greenfield¹, Claire Sutherland¹ and Kristine Swiderek¹. ¹Theraclone Sciences, Seattle, WA.

**Body:** Unlike HER2-positive breast cancer, there are limited treatment options for patients diagnosed with triple negative and endocrine resistant HER2-negative breast cancer, and as such HER2-negative breast cancer represents a significant unmet medical need. The goal of this work is to use Theraclone’s proprietary I-STAR platform to mine the memory B cell immune repertoire of breast cancer patients for the discovery of therapeutically relevant monoclonal antibodies (mAbs) and targets that may be exploited as candidates for treatment of HER2-negative breast cancer.

Matched serum and PBMC samples were collected from breast cancer patients at multiple clinical sites. The selected patient populations included, but were not limited to, patients who were treatment naïve, those who had received immunotherapy or adjuvant chemotherapy, and patients who had an exceptional clinical response to treatment and/or disease. Serum antibody binding to a diverse panel of 5 well characterized breast cancer-derived cell lines of luminal and basal sub-types was determined. Utilizing this approach, patients with a robust serological profile across multiple breast cancer cell lines were identified and prioritized for memory B cell repertoire analysis via the I-STAR platform. Using a high throughput and miniaturized, multiplex flow cytometry assay, the secreted IgG antibodies from over 85,000 individually enriched and expanded B cell clones were screened for binding to the tumor cell line panel and a large number of positive B cell clones were identified. The screening hits can be binned into several unique binding profiles, many of which were confirmed to be shared across multiple patient samples. Deep sequence analysis of the variable regions of the antibodies produced by the B cell clones demonstrated that several of the screening hits were derived from clonally related B cells; the majority of the screening hits represented antibodies derived from unique B cell clones. A representative set of these antibodies was expressed recombinantly for further in vitro characterization.
Title: Bi-specific antibodies targeting signaling pathway crosstalk are a new breast cancer immunotherapeutic strategy

Yanliang Zhang, Edwige Gros, Sarabjit Chagar, Jian Cao, Heyue Zhou, Kouros Motamed, Gunnar F Kaufmann and Yanwen Fu. 1Sorrento Therapeutics, Inc, San Diego, CA.

Body: All of the currently approved therapeutic anti-cancer antibodies are monospecific and therefore only capable of interfering with the biological function of a single molecular target. However, breast cancers mostly involve crosstalk of often synergistic signal transduction pathways, and thus, isolated blockade of a single signal transduction pathway is frequently met by escape mechanisms, such as upregulation of redundant pathways, rendering the monospecific immunotherapy less effective.

Using both chemical and molecular biology techniques, Sorrento has developed new approaches to generate IgG-like bi-specific antibodies (BsAbs) targeting either two compensating signal transduction pathways, such as HER family members, or a breast cancer specific antigen and an immuno-regulatory molecule such as PDL1 or PD1. The chemical biology method, which involves specific hetero-dimerization of two half antibody molecules using bio-orthogonal chemistry, was used to generate an anti-c-Met and anti-PDL1 chemical bi-specific antibody (CBA). Lastly, employing a molecular biology approach, an anti-EGFR and ErbB3 scFv-Fc bi-specific antibody was produced. Progress will be presented on in vitro characterization and cell-based functional assays of these BsAbs.
Title: c-MET is a potential therapeutic target for antibody-drug conjugates in breast cancer

Yanwen Fu1, Edwige Gros1, Alice Lee1, Kimberly Johnson1, Hong Zhang1, Silpa Yalamanchili1, Kouros Motamed1, Gary Chen1, Bryan Jones1, David Miao1 and Gunnar F Kaufmann1. 1Sorrento Therapeutics, Inc, San Diego, CA.

Body: The transmembrane receptor tyrosine kinase c-MET plays a key role in malignant transformation of epithelial cells by activating signal transduction pathways essential for cellular proliferation, survival, migration and invasion. Over expression of c-MET, with or without gene amplification, has been reported in primary breast cancers and correlates with poor prognosis. Inhibition of c-MET signaling, via tyrosine kinase inhibitors (TKIs) or antagonistic antibodies, is usually not sufficient for sustained treatment efficacy, thus, we believe that antibody drug conjugates (ADCs) offer the promise and potential of delivering more potent anti-tumor activity. We have generated ADCs containing a proprietary human anti-c-MET antibody (STI-D0606) with either a tubulin inhibitor or a DNA damaging agent. STI-D0606, a fully human antibody (IgG1) selected from Sorrento's G-MAB antibody library, was conjugated with a cytotoxin via site-specific bioconjugation. The conjugates retained binding affinity and showed potent cell killing in a variety of c-MET-positive cell lines. Progress will also be reported on overall efficacy of c-MET ADCs in a preclinical xenograft model.
**Title:** Overall survival (OS) in the IMELDA randomized phase III trial of maintenance bevacizumab (BEV) with or without capecitabine (CAP) for HER2-negative metastatic breast cancer (mBC)

Hoffmann-La Roche Ltd, Basel, Switzerland; ¹⁷University Hospital of Santa Maria, Lisbon, Portugal and ¹⁸Rajiv Gandhi Cancer Institute & Research Center, Delhi, India.

**Body:** BACKGROUND The open-label randomized phase III IMELDA trial demonstrated that adding CAP to maintenance BEV until disease progression (PD) after initial BEV–docetaxel (DOC) provides statistically significant and clinically meaningful improvements in both progression-free survival (PFS [primary endpoint]; hazard ratio [HR] 0.38 [95% CI 0.27–0.55]; log-rank p<0.001) and OS. We present OS in subgroups representing stratification factors and clinically important populations.

METHODS Patients (pts) with HER2-negative measurable mBC, ECOG PS <2, and no prior chemotherapy for mBC were eligible. After 3–6 cycles of BEV–DOC, pts without PD were randomized to BEV alone or BEV–CAP (BEV 15 mg/kg q3w; CAP 1000 mg/m² bid d1–14 q3w) until PD. Stratification factors were estrogen receptor (ER) status, visceral metastases, response status, and lactate dehydrogenase (LDH) concentration. OS from randomization was a secondary endpoint. The planned sample size of 360 enrolled pts (290 randomized) was calculated assuming a PFS HR of 0.70 (median PFS 5.8 → 8.3 months) with 80% power at 2-sided α=0.05 after 244 PFS events. Recruitment was stopped prematurely after regulatory withdrawal of the BEV–DOC combination but pts who had already been enrolled and randomized were followed as originally planned.

RESULTS Between Jun 2009 and Mar 2011, 284 pts were enrolled and treated. Of these, 99 were not eligible for randomization (most commonly due to PD [41%] or AEs/toxicity [31%]) and 185 (65%) were randomized. At the time of the primary PFS analysis, representing study closure, median follow-up (from randomization) was 31.6 months. Median OS from randomization was 23.7 months in the BEV arm and 39.0 months in the BEV–CAP arm (events in 36% of pts). The HR for OS in the two randomized arms showed consistency between subgroups, favoring the BEV–CAP arm in all subgroups analyzed.

CONCLUSIONS. Combining maintenance BEV with CAP until PD after initial BEV–DOC for mBC provides a statistically significant and clinically meaningful improvement in OS (secondary endpoint), seen consistently irrespective of baseline characteristics.
**Title:** A phase II study of bevacizumab in combination with modified FOLFOX6 in heavily pretreated patients with HER2-negative metastatic breast cancer

Ting Li¹ ², Biyun Wang¹ ², Xichun Hu¹ ², Zhonghua Wang¹ ², Jian Zhang¹ ², Si Sun¹ ², Jun Cao¹ ², Fangfang Lv¹ ², Leiping Wang¹ ², Sheng Zhang¹ ², Chen Ni¹ ², Zhenhua Wu¹ ² and Jie Xie¹ ². ¹Fudan University Shanghai Cancer Center, Shanghai, China and ²Shanghai Medical College, Fudan University, Shanghai, China.

**Body: Background**
Bevacizumab combined with modified FOLFOX6 (mFOLFOX6) is a standard regimen for colorectal cancer with good tolerability. Our previously published study by Sun et al showed a moderate efficacy and excellent safety of mFOLFOX6 for metastatic breast cancer (MBC). This study was to determine the efficacy and safety of adding bevacizumab to mFOLFOX6 in heavily pretreated patients with human epidermal growth factor receptor 2 (HER2)-negative MBC.

**Patients and Methods**
In this open label, single-arm phase II study, bevacizumab, 5 mg/kg every two weeks or 7.5 mg/kg every three weeks, in combination with mFOLFOX6, which were oxaliplatin 85mg/m², leucovorin 400mg/m² and 5-Fu 400mg/m² intravenously on day 1 following 5-Fu 2400 mg/m² continuous intravenously 46 hours every 2 weeks, was administered to patients who failed at least 2 prior chemotherapy regimens in metastatic setting. The prior exposure to taxane, anthracycline, vinorelbine, capecitabine and gemcitabine was 97.9%, 93.8%, 64.6%, 64.6% and 81.3%, respectively. The primary objective was progression free survival (PFS), and secondary objectives included objective response rate (ORR), overall survival (OS) and safety.

**Results**
48 patients were enrolled with a median of 49.5 years old (range, 34 to 73 years old) and a median of 3 prior chemotherapy regimens (range, 2 to 6). A median of 4.0 cycles (range, 0.5 to 8.0 cycles) were delivered with 45 patients undergoing treatment discontinuation, including 7 (14.6%) due to completion of 6 cycles, 1 (2.1%) due to completion of 8 cycles, 18 (37.5%) due to disease progression, 5 (10.4%) due to adverse events, 4 (8.3%) due to withdrawal of informed consent, 2 (4.2%) due to physician’s decision, 2 (4.2%) due to economic reasons and 6 (12.5%) with unknown causes. The median PFS was 6.0 months (95% confidence interval [CI], 3.6 to 8.5 months), ORR was 48.8% and median OS was 10.2 months (95% CI, 8.5 to 11.9 months). Most adverse events were grade 1 or 2 and grade 3 or 4 toxicities occurring in more than one patient were neutropenia (75.0%), leukopenia (50.0%), thrombocytopenia (20.8%) and anemia (6.3%).

**Conclusion**
Adding bevacizumab to mFOLFOX6 has significant anti-tumor activity and excellent safety in heavily pretreated HER2-negative MBC patients, which warrants conduct of further confirmative trials.

**Adverse events compared with our historical mFOLFOX6 trial**

Title: Characteristics and outcome of breast cancer patients enrolled in cancer therapy evaluation program (CTEP) sponsored phase I clinical trials

Filipa Lynce¹, Larry Rubinstein² and Pamela Harris². ¹Washington Cancer Institute, MedStar Washington Hospital Center, Washington, DC and ²Cancer Therapeutic Evaluation Program, National Cancer Institute, Rockville, MD.

Body: Background: Breast cancer is the most commonly diagnosed cancer and the second leading cause of cancer-related death among women. Given the availability of approved therapies and large clinical trials, historically few breast cancer patients are referred for consideration of a phase I trial. Although efficacy is not the endpoint of phase I studies, we were interested in determining whether clinical benefit rates differed in patients with breast cancer from patients with other cancers enrolled in phase I solid tumor trials. In addition a better knowledge of the characteristics and outcomes of patients with breast cancer enrolled in phase I clinical trials may contribute to better clinical trial design and patient selection.

Methods: We performed a retrospective analysis of all Cancer Therapy Evaluation Program (CTEP) sponsored phase I trials for patients with solid tumors, from 1992 to 2012. CTEP phase I database which is maintained by Theradex Inc was queried. Patients treated on phase I/II trials or including hematological malignancies were excluded. We conducted an analysis of demographic variables, variables related to disease characteristics and outcomes of patients with breast cancer and compared them to patients with other oncological diagnoses enrolled in the same trials.

Results: A total of 8119 patients who participated in 225 trials were identified. Of these 1367 (16.8%) patients had breast cancer. Compared with patients with other oncological diagnoses, breast cancer patients were older (51.9 vs. 45.4 years), less likely to be white (73% vs. 81.6%, p<0.001) and more likely to have received a high number of previous lines of therapy (34.2% of patients with breast cancer had received 6 or more prior regimens vs. 11.9% of patients with other cancers, p<0.001). Performance status (PS) was similar between the two groups of patients with the majority of patients presenting with PS of 1 (57.3% in the breast cancer group and 60.9% in the non-breast cancer group). The clinical benefit rate was higher for patients with breast cancer (56.1% vs. 42%, p<0.001). Breast cancer patients remained on study longer than non-breast cancer patients (mean 136.3 vs. 95.8 days, p<0.001). The toxicity related deaths were less than 1% in both groups. Discontinuation of treatment due to toxicity was observed in 6.6% of patients with breast cancer and 5.6% of patients with other cancers.

Conclusions: An analysis of the CTEP-sponsored phase I trials revealed that breast cancer patients, enrolled in these trials, were older and more heavily pre-treated than patients with other types of cancer. However they seem to have better outcomes and similar toxicities when compared to the other patients. These data suggest that patients with breast cancer who have likely exhausted treatment with approved agents should be considered for phase I trials.
Title: Potential benefits of hypnosis sedation on different modalities of breast cancer treatment

Martine Berliere¹, Sarah Lamerant¹, Philippe Pietet², Aurore Lafosse¹, Laurence Delle Vigne¹, Fabienne Roelants¹, Christine Watremez¹, Marie-Agnes Docquier¹, Lafita Fellah¹, Isabelle Leconte¹ and François Duhoux¹. ¹Cliniques Universitaires St Luc (UCL), Brussels, Belgium and ²Grand Hopital de Charleroi (GHdC), Charleroi, Belgium.

Body: Background: In oncology, hypnosis has been used for pain relief in metastatic patients but rarely for induction of anaesthesia.

Material and methods: Between January 2010 and February 2014, 220 patients from our breast clinic (Cancer Center - Cliniques universitaires Saint-Luc - Universite catholique de Louvain) were included in an observational, non randomized study approved by our local ethics committee. 110 consecutive patients underwent breast surgery (lumpectomy or mastectomy +/- axillary lymph node dissection or sentinel lymph node biopsy) while on general anaesthesia (group I) and 110 consecutive patients underwent the same surgical procedures while on hypnosis sedation (group II). The stages and the tumor characteristics were well balanced between the two groups. After surgery, 28 patients received chemotherapy in group I and 27 patients in group II. Radiotherapy was administered to 96 patients of group I and 95 patients of group II. Currently, 83 patients of group I and 82 patients of group II are receiving endocrine therapy. Different parameters were studied for each treatment modality.

Results: Duration of hospitalization was statistically significantly reduced in group II vs. group I (3.3 days vs. 4.4 days) (CI 95% range: -1.48 -0.72, p=0.000000578) for all surgical procedures. The same results were observed for mastectomies alone (3.1 vs. 5.3 days) (CI 95 % range: -3.19 -1.31, p=0.0012) and for lumpectomies (3.1 vs. 4.3 days) (CI 95 % range: -1.024 -0.364, p=0.00065). The number of post-mastectomy lymph punctures was reduced in group II (1 to 3 (median value n=1.6) vs. group I (2 to 5 (median value n=3.1, p=0.01), as was the quantity of lymph removed (103 ml versus 462.7 ml) (p=0.0297) in the group of mastectomies.

Concerning chemotherapy, the incidence of asthenia was statistically decreased (p=0.015) in group II. There was a statistically non significant trend towards a decrease in the incidence of nausea/vomiting and muscle pain in group II (respectively p=0.1 and p=0.2).

The frequency of severe radiodermatitis (p=0.01) and post-radiotherapy asthenia (p=0.01) were significantly reduced in group II. Finally, compliance to endocrine therapy was improved in group II (p=0.05), while incidence of hot flashes (p=0.00029), joint or muscle pain (p=0.000139) and asthenia (p=0.00002) were statistically significantly decreased in group II.

Discussion: Hypnosis sedation exerts beneficial effects on nearly all modalities of breast cancer treatment. The absence of a significant benefit for chemotherapy-induced nausea/vomiting and muscle pain observed is probably due to the small number of patients receiving chemotherapy in our study.

Conclusion: Benefits of hypnosis sedation on breast cancer treatment are very encouraging and further promote the concept of integrative oncology.
Body: Objective: Treatment of patients with a history of breast cancer who are diagnosed as newly found solid pulmonary nodule is still controversial. Our study is to find out whether the pulmonary nodule represents a primary cancer, metastasis, or benign lesion secondary to breast cancer can be differentially prognostic.

Methods: A total of 165 consecutive patients who underwent surgery or biopsy for pulmonary nodules between 2007 and 2013 after curative operation for breast cancer were reviewed. The postoperative survival rate was analyzed and the difference in survival rate was assessed between groups of pulmonary nodules representing a primary cancer, metastasis, and benign lesion.

Results: Among these 165 patients, median age was 59 and mean follow-up was 51 months (range from 5 to 398). The pathologic diagnoses of pulmonary nodules were pulmonary metastases of breast cancer in 71 patients (43%), primary lung cancer in 59 (35.8%), and other diagnoses in 35 (21.2%) (hyperplasia in 11; pneumonia in 9; granuloma in 6; sclerosing hemangioma and pulmonary fibrosis in 4 each). In those who were diagnosed as malignant pulmonary tumor, about one half (56.4%) were secondary malignant and the rest were metastatic. There was no statistically difference in median age or disease free interval between operation date of breast surgery and pulmonary surgery or biopsy among these groups. However, those who were diagnosed as primary malignant or benign lesion had significantly higher incidence of isolated pulmonary nodule shown on their CT scan results (P=0.036). The incidence of positive lymph node involvement and negative ER/PR status was significantly higher in metastatic breast cancer patients (63.8% and 70.6%, respectively). Among patients with metastatic pulmonary nodules, rates of discordance between primary breast tumor and metastasis foci were 20.3%, 23.7% and 14.7% for ER, PR and HER2, respectively, which changed a lot the regimen used for treatment of metastatic breast cancer. Both the 5-year and 10-year disease-free survival from the initial mastectomy were significantly shorter in metastatic breast cancer patients (72.9%, 35.3%) when compared with patients with primary pulmonary cancer (82.9%, 53.8%) or pulmonary benign lesions (91.6%, 67.8%). Prognostic factors in metastatic breast cancer patients were a disease-free interval of >60 months with 10-year survival of 48.3% (P<0.05), solitary lung metastasis is associated with a survival rate of 78.9% after 5 years and of 48.7% after 5 and 10 years, and this is statistically significant compared to multiple metastases.

Conclusions: We think that pulmonary lumpectomy is the best option in selected cases of solitary or multiple pulmonary nodules from breast cancer, which can be useful for differential diagnosis, predicting prognosis and deciding the drug treatment strategy in some cases.
Title: Isolated loco-regional recurrence in the breast: Re-quadrantectomy and systemic treatment

Victoria Costanzo1, Veronica Fabiano1, Mercedes Maino1, Federico Colo1, Reinaldo Chacon1, Adrian Nervo1, Jorge Nadal1, Martin Loza1, Jose Loza1, Daniel Mysler1 and Mora Amat1. 1Instituto Alexander Fleming, Buenos Aires, Argentina.

Body: Background: Local or regional recurrence in breast cancer is associated with poor prognosis. Mastectomy is the classic indication in these situations. However, second attempts of breast conservation in previously radiated patients with small, histologically favorable local relapse have been reported. Also, prospective data (The CALOR Trial) suggest that adjuvant chemotherapy should be recommended in patients with isolated loco-regional recurrence, especially if the recurrence is HR negative. The purpose of our study was to determine the frequency of use of re-quadrantectomy and systemic treatment in isolated loco-regional recurrence (ILR) in breast cancer.

Methods: Retrospective review of the database of our institution. Inclusion criteria: ILR in surgical bed, breast or lymph nodes with complete resection (mastectomy, re-quadrantectomy or axillary resection) with or without systemic treatment and radiotherapy. Findings: 4695 patients were analyzed from april 2000 to april 2014. 78 patients had a ILR, 66 were analyzed. Median age 49.5 years (27-86). 54.5% of the patients were postmenopausal and 16.6% had bilateral involvement at diagnosis. Characteristics of the primary tumor: Mean tumor size 2 cm, 66.6% were HR positive, 6% HER2 positive, 13.6% TN and 14% unknown. Initial treatment: breast conserving surgery 62 p (sentinel node 25, axillary node dissection 36); mastectomy 4 patients. 42 patients underwent adjuvant chemotherapy, 57 patients radiotherapy and 62 patients hormonotherapy. Time to recurrence: 94.3 months. Characteristics of the ILR: Mean tumor size 1.8 cm. 65% were HR positive, 12% triple negative, 6% HER positive and 17% unknown. Treatment at relapse was as follows: 27 re-quadrantectomy, 34 mastectomy, 1 lymph node dissection; all these patients had previous quadrantectomy. The other patients underwent to mastectomy (1) and complete resection of the lesion (3). 29 patients received chemotherapy (43.9%), : 70% anthracyclines and taxanes, 6% trastuzumab, 30% other and 65% received hormonotherapy. Local progression free survival 30.7 months; distance progression free survival 100 months. Local relapse was evidenced in 30% of patients who had a re-quadrantectomy procedure.

Conclusions: Second attempt of breast conservation in previously radiated patients with small, histologically favorable ILR and long recurrence free interval disease is feasible as described. The target population is of good prognosis as evidenced the long free disease interval at recurrence (94.3 m), the mean size of tumor at recurrence (1.8 cm) and the high proportion of HR positive disease. The percentage of local recurrence after re quadrantectomy is as described in some reports, 30% (20-35%). The indication of chemotherapy was mostly in HR negative or HER 2 positive tumors, but the low number of patients does not permit a valid comparaison.

Title: Low dose capecitabine is effective and relatively nontoxic in breast cancer treatment

John Carpenter¹. ¹University of Alabama, Birmingham, AL.

Body: Capecitabine has been widely used in treatment of both early and advanced breast cancer in the United States since 1998. The dose limiting toxicity is diarrhea, which is dose limiting and can be severe. Lower doses are widely used without any apparent compromise in efficacy and are consistently less toxic (see Naughton, Clinical Breast Cancer 2010). Here a continuous dose regimen of capecitabine 1000 mg. daily was used in 24 patients with breast cancer, both early and advanced, from March 2012-September 2013. Four received the drug as adjuvant treatment, 8 as preoperative therapy, and 12 for advanced disease. Duration of treatment ranged from 0.5 to 15 months. Toxicity was modest: 1 had moderate nausea, none experienced vomiting, 2 mild anemia (one with marrow replacement by tumor), 2 mild palmar irritation, and 1 grade 1 thrombopenia. No diarrhea was seen. One patient died of hepatic necrosis and portal vein thrombosis; the relationship to treatment was uncertain. 12/20 with measurable disease experienced a response to treatment (1 complete and 11 partial responses by RECIST criteria), 1 had stable metastatic disease for 9 months, and 7 had progression of disease. The median duration of response was 5 months (range 2-15 months). Use of capecitabine in this dose and schedule for treatment of breast cancer appears comparably effective to higher conventional doses and dramatically less toxic.
Title: Can synthetic 2D mammography be used to select patients in whom there is no need to review the digital breast tomosynthesis from which they were constructed? A review of 1871 consecutive mammogram sets of patients presenting symptomatically or for follow up

Simon DH Holt¹, Ali Moalla¹, Helen R Williams¹, Khaldoun MY Nadi¹, Anita M Huws¹, Amrita Gurung¹, Daniel Thomas¹ and Yousef M Sharaiha¹. ¹Peony Breast Care Unit, Prince Philip Hospital, Llanelli, Carmarthenshire, United Kingdom.

Body: Introduction: A synthetic 2D mammogram can be created by combining the individual optimally enhanced 1mm slices of a digital breast tomosynthesis (DBT). Theoretically this could help overcome the problems associated with standard 2D mammograms (superimposition of structures hiding small cancers) and the significantly increased reading time and decreased conspicuity of microcalcifications associated with DBT. It may avoid the need for the double x-ray exposure required for combination 2D and DBT currently being suggested to maximise the specificity and sensitivity of mammography. The hypothesis we wished to test is, “if the synthetic 2D is normal, is there any advantage to looking at the DBTs as well?”

Method: We have reviewed 1000 consecutive cases presenting symptomatically or to our follow up clinic all of which underwent DBT on a Hologic Dimensions machine. From the 3D data sets synthetic 2D mammograms were constructed (Hologic C-view technology). One breast radiologist with 12 years experience of interpreting mammograms and more recently 4 years experience in interpreting DBTs was asked to first review the 2D synthetic mammograms (each breast CC and MLO) and report them before then reviewing the DBTs and issuing a final report. The mammograms were reported M1 to M5 using the standard BIRADs criteria. The BIRADs scores for each breast were recorded prospectively and entered into a database.

Results: 1000 consecutive patients were studied between October 2013 and March 2014. The average age of the women was 58.1 years (range 29 to 92). Of these some were under follow up after mastectomy so in total there were 1871 individual mammogram sets reported. Table 1 summarises the correlation between C-view and DBT reporting. The correlation between the two modalities is very close, but importantly there was only one patient in whom the C-view was reported normal or benign (M1 or M2) but the DBT reported a possible abnormality (M3). However, 31 cases reported as suspicious or malignant M3, 4 or 5 by C-view were subsequently downgraded to benign after review of the DBT.

Table 1

Conclusion: In a symptomatic and follow up clinic, our study suggests that much radiologist’s time and x-ray exposure to the patient could be saved by using synthetic 2D mammograms derived from the DBT data rather than using separate 2D studies. Only if the C-view is reported M3, 4 or 5 is it necessary to review the DBT but for all these patients the DBT is already available without further x-ray exposure or recall.
Clinical, anatomical and histological characteristics of breast lesions visualized by photoacoustic mammography; first clinical study in CK project

Elham Fakhrejahani, Masae Torii, Yasufumi Asao, Iku Yamaga, Toshiyuki Kitai, Masako Kataoka, Shotaro Kanao, Masahiro Takada, Tsuyoshi Shiina and Masakazu Toi. Kyoto University, Kyoto, Japan; Kishiwada City Hospital, Kishiwada, Osaka, Japan and Canon Inc, Tokyo, Japan.

Background: Photoacoustic mammography (PAM) is an optical imaging technique potentially capable of imaging breast vasculature as well as measuring hemoglobin oxygen saturation (SO2) in focal breast lesions. We presented the initial observation on first 20 cases using the first generation PAM (PAM-01) prototype made by Canon Inc. (Tokyo, Japan) (spatial resolution: 2mm) in SABCS 2013. Here we report the clinico-pathological characteristics of all cases recruited in the first clinical study in CK project (Kyoto University/Canon joint research project) between Aug 2010 and March 2012.

Methods: 57 patients were recruited in IRB approved study at Kyoto University Hospital, Japan. Forty-two breast harboring lesions and when possible contralateral breasts were evaluated by PAM-01. Axial maximum intensity projection (MIP) were obtained and signals from consecutive MIPs confirmed to be associated with the tumor location in MRI by an expert breast radiologist were considered to be the region of interest (ROI). Histological sections from the widest area of the lesions were evaluated post-excisional by immunohistochemistry using anti-CD31 as endothelial marker and anti-carbonic anhydrase IX (CA IX) as hypoxia marker. Histological slides were scanned and divided into 1680 squares (0.84x0.84 mm²) (Hamamatsu Inc. Japan) for image analysis. Total vascular perimeter (TVP)-in mm- was calculated for all the histological section by using Image Pro-Plus 7.0 software (Media Cybernetics, USA). Tumor area was measured in mm². TVP index was calculated as TVP/area.

Results: Photoacoustic signal was detected in 30 lesions out of 42 at the depth of 26.8 ± 12.8 mm from which 80% were located superior to nipple. CA IX positive cases in comparison with CA IX negative cases significantly showed higher TVP index (p-value = 0.028 Mann-Whitney Test) suggesting more angiogenic profile of hypoxic tumors. However, lesions without any detectable signal were reported to have only a bigger mass size histologically (26.6 vs. 14.8 mm, p-value 0.28, Mann-Whitney Test) regardless of their TVP index or CA IX expression level. Moreover, SO2 was calculated 70.9% for signals located inside tumors and 85.5% for signals associated with subcutaneous vessels in the same breast (p-value <0.0001 Wilcoxon Test) compatible with the SO2 data from normal counterpart at tumor depth in the other breast (81.9%) (p-value 0.0001 Wilcoxon Test). Tumors bigger than 2 cm also tended to have lower SO2 (65.6%) compared with tumors smaller than 2 cm (70.1%) in accordance with higher TVP index in bigger tumors (p-value <0.001 Student T-test).

Conclusion: This is the largest clinical study of PAM till today and the correlation between histological profile of hypoxia and tumor microvasculature with PAM signal visibility as well as tissue SO2 seems promising. However, the improvement of techniques and resolution is necessary to develop a more clinically applicable non-invasive functional breast imaging modality for analyzing breast tumor vasculature and hypoxia. Some of these improvements have taken place for the second generation PAM (PAM-02) which is now under a clinical evaluation study.
Title: Are more frequent early follow up mammogram protocols necessary after breast conserving surgery and radiation therapy?

Chavi Kaufman¹, Tamara Fulop¹, Susan K Boolbol¹, David Lucido¹, Suzan Naam¹, Alyssa Gillego¹ and Manjeet Chadha¹. 'Beth Israel Medical Center and Roosevelt Hospital, NYC.

Body: Background: In an era of choosing wisely in healthcare there are many initiatives in radiology and oncology that are being evaluated for appropriateness of practice based on clinical evidence-base. More frequent follow up mammogram protocols in the first 3 years after BCT are a widely accepted practice. However, such breast imaging schedules have no strong clinical evidence-base to support the added testing every 6-months, nor a rationale to justify patient anxiety and added unnecessary biopsy procedures. The goal of our study was to evaluate the frequency of BIRADS score 4 on short follow up mammograms in a population of patients treated with breast conserving surgery and RT (BCT).

Materials and Methods: This is an IRB approved study. From 2001- 2007, we identified 681 patients who underwent BCT and who also underwent follow up mammograms at our cancer center. We reviewed short follow up mammograms defined as those obtained within the first 3-years after BCT. The BIRADS score was tabulated in all cases. Further, it was determined to study the frequency of BIRADS 4 score only, because this was deemed a clinically significant finding that routinely warranted additional evaluation.

Results: Median age of the study group is 51 years (31- 80 years). Among the 681 patients a total of 3648 follow up mammogram sessions were obtained. The median number of follow up mammogram sessions per patient during the observation period of 3-years was 6 (range 2-6 mammogram sessions). In 85% of patients followed the mammogram scores were BIRADS 1 to 3. In 15% of the patients the BIRADS score 4 was reported at least once. Among the BIRADS 4 category of patients, 56% had this score reported in the ipsilateral breast following BCT for breast cancer, and 44 % had BIRADS 4 reported in the contralateral breast. Specifically, in the ipsilateral breast the frequency of BIRADS 4 was 8.2%. We also observed a significant trend with a higher frequency BIRADS 4 reported within the first year of follow up in the ipsilateral breast as compared with the contralateral breast. In the 2nd and 3rd year the frequency of BIRADS 4 was < 10% and comparable between the treated ipsilateral breast and the normal contralateral breast. The pathology correlations showed a significantly lower yield of cancer in the BIRADS 4 subset of patients.

Conclusions: Similar to the observations of the ACRIN 6666 study ¹ on BIRADS 3 we observed a very low yield of cancer from frequent follow up protocol for the ipsilateral breast using the BIRADS 4 category. In promoting responsible medical care it is important to establish appropriate follow up guidelines and selection of schedules for groups of patients individualized by risk. Annual follow up mammograms might be adequate frequency for the ipsilateral breast. This study warrants further evaluation and standardized protocols.

Mammographic changes after oncoplastic reduction mammoplasty

Anne Warren Peled¹, Merisa Piper¹, Laura J Esserman¹, Robert D Foster¹, Hani Sbitany¹ and Elissa R Price¹. ¹University of California, San Francisco, CA.

BACKGROUND:
Reconstruction of partial lumpectomy defects with reduction mammoplasty techniques can improve aesthetic outcomes. However, the impact of the significant tissue rearrangement on post-operative mammographic findings and subsequent recommendations for biopsy has not been well-studied.

METHODS:
A retrospective review of 50 patients who underwent partial mastectomy with immediate oncoplastic reduction mammoplasty reconstruction from 2001 to 2008 was performed. Mammography reports at 6 months, 1 year, 2 years, and 3 years post-operatively were reviewed for Breast Imaging Reporting and Data System (BI-RADS) scores, predominant findings, and recommendations for subsequent imaging or biopsy.

RESULTS:
At six months post-operatively, 49 patients (98%) had benign findings of post-surgical changes, while one patient had microcalcifications and underwent subsequent surgical re-excision with residual DCIS on pathologic analysis. At one year, 94% of patients continued to have benign mammograms; of these mammograms, 94% reported only post-surgical scarring, while 6% described benign-appearing scattered or dystrophic calcifications. Of the three patients with suspicious mammograms at one year, all underwent core biopsies with benign results. At two years, rates of fat necrosis (2%) and scattered or dystrophic calcifications (10%) increased, though all mammographic findings were considered benign and none required additional imaging or biopsies. By three years post-operatively, an additional two patients (4%) developed suspicious findings and underwent biopsies confirming local recurrence (one invasive, one in situ). The remaining 96% continued to have benign mammographic findings and were subsequently followed with routine biannual mammographic surveillance.

Overall, 88% of patients required no additional intervention in the three-year period following oncoplastic reduction mammoplasty. Of patients recommended for biopsy, malignancy was discovered in 50%, including two local recurrences (4% of total patients). This data is similar to a previously published large study (1841 women) of mammographic surveillance after partial mastectomy without oncoplastic reconstruction at our institution, which found a 6% malignancy rate at 5 years.

CONCLUSIONS:
Although substantial tissue rearrangement is performed at the time of oncoplastic reduction mammoplasty, our results demonstrate low rates of abnormal post-operative mammograms and subsequent biopsies over the first three years following the procedure. These findings support the use of oncoplastic reduction mammoplasty as a strategy for improving reconstructive outcomes in patients undergoing partial mastectomy.
Title: The aggregate number of false-positive recalls and biopsies performed under different breast cancer screening strategies in the US

Carlie K Thompson¹, Cristina O'Donoghue², Elissa M Ozanne³, Martin Eklund¹ and Laura J Esserman¹. ¹University of California, San Francisco, CA; ²University of Illinois at Chicago, Chicago, IL and ³Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, NH.

Body: Introduction

The ideal screening program optimizes benefits while reducing harms. The balance of benefits and harms with breast cancer screening is debated. This study aims to inform breast cancer screening policies by calculating the aggregate number of false-positive recalls and false-positive breast biopsies under different screening strategies.

Methods

We created a model to estimate the number of screening mammograms, false-positive recalls and false-positive biopsies performed per year in the US based on current practice. The percent of women that participate in screening under current practice was estimated from the 2010 CDC Behavioral Risk Factor Surveillance System. The model also enabled the comparison of 3 screening strategies: annual, biennial, and United States Preventive Services Task Force (USPSTF) guidelines, using a target participation rate of 85%. The number of women at risk in each age group was taken from the US Census and excludes women who have had breast cancer in the past five years. False-positive recall rates and biopsy rates were obtained from Hubbard et al. (Ann Intern Med, 2011). Analyses were performed using R statistical software. Outcomes for this analysis were the total number of false-positive recalls and biopsies. Monte Carlo methods were used to compute 95% confidence intervals.

<td>2.7x10^5 (2.1x10^5-3.5x10^5)</td>
</tr>
</tbody>
</table>

Conclusion
Compared to annual screening, we estimate that following the USPSTF guidelines would result in 62% fewer false-positive recalls and 58% fewer false-positive biopsies. The absolute magnitude is in the range of 374,000 biopsies annually. Given that these screening strategies have been projected to be of equal benefit, more widespread adoption of the USPSTF guidelines could decrease the patient risk and anxiety associated with recall and biopsy without impacting the benefits. Developing tools for personalized risk assessment would facilitate adoption of the USPSTF guidelines. These tools can be tested by comparing the personalized and annual screening strategies prospectively and can inform screening policies.
Title: Impact of breast density notification laws on radiology practices: A survey of 110 radiology facilities

Lina Nayak¹, Kanae K Miyake¹, Yueyi Irene Liu¹, William R Thomas¹, Edward A Sickles², Bonnie N Joe², Karen Lindfors³, R J Brenner⁴, Stephen Feig⁵, Lawrence W Bassett⁶, Jessica W Leung⁷, Haydee Ojeda-Fournier⁸, Jonathan Hargreaves³, Elissa Price⁸, Jafi A Lipson¹, Allison W Kurian¹, Elyse Love⁸, Donna D Walgenbach³, Lauren Ryan², Meg Durbin⁹, Bruce L Daniel¹, Linda Garcia⁶ and Debra M Ikeda¹. ¹Stanford University, Stanford, CA; ²University of California, San Francisco, CA; ³University of California, Davis, CA; ⁴Alta Bates Summit Medical Center, Berkeley, CA; ⁵University of California, Irvine, CA; ⁶University of California, Los Angeles, CA; ⁷California Pacific Medical Center, San Francisco, CA; ⁸University of California, San Diego, La Jolla, CA and ⁹Palo Alto Medical Foundation, Palo Alto, CA.

Body: Purpose: Breast Density Notification laws, passed in 15 states as of April 2014, mandate that breast density information be given to patients often without guidance on modalities, patient selection or funding for supplemental screening. The purpose of this study is to assess the impact of breast density notification laws on radiology practices, specifically regarding breast cancer risk assessment and supplemental screening studies.

Methods: We performed an anonymous 20-question web-based survey to Society of Breast Imaging radiologists using a Qualtrics Survey Tool between 8/2013-3/2014, with questions on radiology practices, breast cancer risk assessment, breast density measurement, supplemental screening tests, and support for referring physicians and patients. We compared survey results between groups using Fisher’s exact test.

Results: 121 radiologists from 110 facilities (48 academic, 43 large private hospital, 15 small private hospital and 4 other) representing 34 USA states and 1 Canadian site responded. 49% of facilities (54/110) were in states with an enacted breast density notification law. 37% of facilities (40/109) performed risk assessment, 26% (28/109) did not perform risk assessment, and 38% (41/109) did not but reported family history/other risk factors, with no significant difference in performing risk assessment between facilities with or without an enacted law (p-value 0.71). Of the 37 facilities performing risk assessment, 60% used the Gail model, 22% used the Tyrer-Cuzick model and 11% used the modified Gail model (multiple answers allowed [m.a.a.]). Of the 15 facilities performing risk assessment, 40% answered "yes" when asked whether performing risk assessment is a new task because of the density law. Breast density was estimated by only visual assessment in 98% of facilities (103/105), and by computer-based determination with or without visual assessment in 2% (2/105). Supplemental screening studies offered included magnetic resonance imaging (MRI) (88%, 92/105), handheld whole breast ultrasound (HHWBUS) (48%, 50/105), tomosynthesis (39%, 41/105), and automated WBUS (8%, 8/105) (m.a.a.). There was no significant difference in supplemental screening studies offered between facilities with or without an enacted law (p-value 0.26). In anticipation of the law, facilities implemented HHWBUS (33%, 16/48), tomosynthesis (6%, 3/48), automated WBUS (6%, 3/48) or none (60%, 29/48) (m.a.a.). Facilities with the enacted law prepared for the law with referring physician discussions (69%, 34/49), website (49%, 24/49), educational talks for referring physicians (43%, 21/49) or patients (31%, 15/49) (m.a.a.).

Conclusion: Our survey showed variations in available supplemental screening modalities and policy implementation at each facility. There was no significant difference in performing risk assessment and supplemental screening studies between facilities with or without an enacted breast density notification law.
Title: Breast cancer screening by women from BRCA1 & BRCA2 mutation positive families

Melanie Wuttke¹, Roger Milne², Prue Weideman¹, Sandra Picken¹, Charmaine Smith¹, Michael Friedlander³, kConFab Investigators¹, Sue-Anne McLachlan⁴, John L Hopper² and Kelly-Anne Phillips¹. ¹Peter MacCallum Cancer Centre, Melbourne, Victoria, Australia; ²University of Melbourne, Melbourne, Victoria, Australia; ³Prince of Wales Hospital, Sydney, New South Wales, Australia and ⁴St Vincent's Hospital, Melbourne, Victoria, Australia.

Body: Purpose: Breast screening may detect breast cancer (BC) at an early stage but optimal screening depends on a woman’s level of risk and age. This study estimates the contemporary prevalence of BC screening by Australian women from families with a BRCA1/2 mutation identified by Family Cancer Clinics.

Methods: Subjects were carriers and true non-carriers from families with a BRCA1/2 mutation enrolled in the nationwide kConFab cohort. They are followed up every 3 years with a questionnaire which includes use of breast ultrasound, mammography (MMG), magnetic resonance imaging (MRI) and clinical breast examination (CBE) over the previous 3 year period. Data from each woman’s most recent questionnaire (completed Oct 2009- March 2014) were used in the analysis. All knew their mutation result. Those who had risk-reducing mastectomy, previous cancer, were evaluated for benign breast disease, pregnant or breastfeeding or received their mutation result in the most recent follow-up round were excluded. Screening behaviour was categorized based on current national guidelines (see table). Associations with underscreening and overscreening were assessed using unconditional logistic regression to estimate odds ratios and 95% confidence intervals.

Definitions of overscreening and underscreening for carriers & true non-carriers

<table>
<thead>
<tr>
<th>Groups</th>
<th>Overscreening*</th>
<th>Underscreening*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carriers</td>
<td>Breast imaging (MMG +/- MRI) more often than annually</td>
<td>Breast imaging less often than annually if age ≥30</td>
</tr>
<tr>
<td>True non-carriers</td>
<td>Age &lt;40: any screening MMG; age ≥40: MMG more often than every 2 years OR any MRI or ultrasound screening</td>
<td>Age 50-70: MMG less often than every 2 years</td>
</tr>
</tbody>
</table>

*Definitions derived from Cancer Australia Guidelines which do not recommend for or against CBE in any group and differ from US guidelines.

Results: Of 372 eligible participants, there were 92 mutation carriers (42 BRCA1, 50 BRCA2) and 280 true non-carriers. 1% of carriers were overscreening, 86% were screening annually while 13% were underscreening. MRI, which is funded for mutation carriers aged 30-50 years, was used by only 52% (13/27) of carriers aged <50 years and by 7 carriers aged ≥50. Underscreening carriers were more likely to be single (OR=2.78, 95%CI=1.28-5.88, P=0.009) while those with a first degree cancer affected relative were less likely to underscreen (OR= 0.40, 0.19-0.85, P=0.017). CBE was undertaken by 79% of carriers at least yearly; 15% had no or irregular CBE.

115/280 (41%) non-carriers were overscreening, 55% were screening appropriately and 5% were underscreening. Underscreening non-carriers were more likely to be single (OR 3.85, 95%CI=1.00-14.9, P=0.05). Predictive of overscreening in non-carriers was having a cancer affected first degree relative (OR=2.92, 1.55-5.51, P=0.001). Non-carriers were less likely to utilise CBE (54%).

Conclusion: Most mutation carriers in kConFab are having regular screening MMG, but MRI is underutilised even when funded. The reasons for low usage of MRI requires further research and is concerning given its increased sensitivity over MMG. Overscreening is common in true non-carriers of BRCA mutations. Family cancer history and marital status may predict inappropriate screening behaviour.
The contribution of the national health system to mammographic screening in Brazil

Ruffo Freitas-Junior¹, Danielle CN Rodrigues¹, Rosangela S Correa², João-Emilio Peixoto³ and Rosemar MS Rahal¹. ¹Program of Mastology, Federal University of Goias, Goiania, Goias, Brazil; ²CNEN, Comissao Nacional de Energia Nuclear, Goiania, Goias, Brazil and ³National Cancer Institute, Rio de Janeiro, Brazil.

INTRODUCTION: In Brazil, access to mammography is provided through the National Health System (SUS), the Supplemental Health System, or is paid for directly by the patient. SUS is the official government system and was established to conform to the constitutional requirement that health is a right of all Brazilian citizens and a duty of the state. In recent years SUS breast cancer control policies have advanced and government strategies for early detection have strengthened. However, evaluations are needed to monitor the effectiveness of these actions. OBJECTIVE: To describe the coverage of mammography in breast cancer screening conducted by the National Health System in Brazilian macro-regions and states in 2012. METHODS: An ecological study, where the estimate of coverage was the number of exams performed expressed as a percentage of the number of exams expected in the target population of women 50-69 years old. The exams performed refer to target population mammography production data from the Outpatient Information System (CIS) of DATASUS. To calculate the expected number of exams for this population, the biennial screening recommendations of the National Cancer Institute (NCI) and an estimate of the female population based on the census of the Brazilian Institute of Geography and Statistics (IBGE) were used. RESULTS: The coverage estimate for SUS-performed mammography in Brazil in 2012 was 26.6%. Stratified by macro region, the lowest coverage was in the northern region (12.1%) and highest in the South (34.6%).

* Chi-square test

Units of the Federation an estimated coverage ranged from 0.2% to 41%, the lowest in the state of Amapa and the largest in Santa Catarina. 48% of states were in the range of 10.1% to 20% coverage. CONCLUSION: The results imply that the contribution of SUS to mammography screening in Brazil is higher in both macro-regions and states with higher income and better organised health system.
Title: Qatar experience of Standard risk breast cancer screening program (BCSP)

Salha Bujassoum¹, Reena Alassam¹, Hekmat Bugrein¹ and Mufid Elmistiri. ¹Hamad Medical Corporation, Doha, Qatar.

Body: Background
Qatar has one of the highest age-adjusted breast cancer incidences in the Arab world. Although this is much lower than the incidence in the West. Breast cancer incidence in Qatar was 45 per 100,000 in 2003-2007 & 53 per 100,000 in 2008-2011. These higher incidence rates in Qatar are mainly due to the growing population. The prevalent age group, for Qatari and non-Qatari patients, was 40-50 years old. This suggests that the age-specific incidence of breast cancer in Qatari women is unlike the pattern usually seen in Western nations where median age at diagnosis is 61 years, moreover the diagnosis is often at advanced stages of breast cancer. These factors led to establishment the first hospital based (BCSP) in Qatar. It uses a distributed model of mammography service. The program launched 2008, accepts eligible asymptomatic women at ages 40 - 69 years.

Methods
A retrospective study was done during the period from April 2008-December 2013. Our aim is to describe our experience of (BCSP) in Qatar and to monitor performance indicators. Our (BCSP) includes an office call and recall as well as triple assessment. We also discuss positive cases in multi-disciplinary meeting. Supplement women satisfaction survey conducted along with screening for 100 women showed highly overall satisfaction reached 90%.

Results
Total number of screened women was 4264 with an increasing participation, year by year. Out of these, Qatari patient's accounts for 1145, and non Qatari for 3119. The age group of cases was (43-51). Total breast biopsies were 82, of which 45 were positive of breast carcinomas, (37) invasive ductal carcinoma, (8) noninvasive ductal carcinoma. The Invasive cancer detection rate was 8.2 %. The positive predictive value (PPV) was 46%. Sensitivity value has improved from 51% in 2008 to 70% in 2012 as well as specificity value that has increased from 77% in 2008 to 83% in 2012.

Conclusion
Public acceptance of the breast cancer screening program in Qatar gradually increased and women highly satisfied about the services, incidence rate higher in age group (43-52) years. Invasive detection rates were higher compare to the western counters, this indicate either aggressive behavior of the disease or women come forward to screening without knowing that they are symptomatic, in this part of the world. We have a unique population of multinationals that merits tailored screening tools .and intensify the public awareness and early deflection screening program.
Title: Diagnostic performance of PET/CT and bone scintigraphy in breast cancer patients with suspected bone metastasis

Naoki Niikura¹, Jun Hashimoto², Toshiki Kazama², Jun Koizumi¹, Rin Ogiya¹, Mayako Terao¹, Risa Oshitanai¹, Toru Morioka¹, Banri Tuda¹, Takuho Okamura¹, Yuki Saito¹, Yutaka Imai¹ and Yutaka Tokuda¹. ¹Tokai University School of Medicine, Japan and ²Tokai University School of Medicine, Japan.

Body: Introduction

Previous retrospective studies suggest that 18FDG PET/CT (PET/CT) has superior sensitivity and specificity to bone scintigraphy (BS) in detecting breast cancer bone metastases, but the difference in efficacy between these techniques has not been confirmed. Potentially, PET/CT may detect bone metastases more accurately than BS does. To test this hypothesis, this prospective study compared the diagnostic efficacy to detect bone metastases between PET/CT and BS in breast cancer patients. We also compared the response of bone metastases assessed by the PET/CT or BS with the bone metastases.

Method

This single-institution prospective study included consecutive patients with breast cancer diagnosed by biopsy and suspected bone metastases at the Breast Diseases Unit at Tokai University Hospital, Kanagawa, Japan between September 2011 and March 2014. Inclusion criteria were as follows: bone pain, elevated alkaline phosphatase, elevated tumor marker, and suspected bone metastases on BS. Two nuclear medicine physicians interpreted the PET/CT and BS images. Bone involvement was confirmed by biopsy, especially in the case of oligometastasis. If biopsy proved difficult to perform, conventional imaging and additional directed radiological studies and follow up were helpful. This study was approved by the Institutional Review Board of the Tokai University School of Medicine and is registered with UMIN, number 000006003. All patients provided informed consent.

Result

Thirty patients were initially enrolled, but two patients were excluded from analysis because they declined further follow-up imaging. The median patient age at diagnosis was 59 years (range, 31–74 years). Among the 28 patients, bone pain was observed in 6 patients, elevated alkaline phosphatase in 4, elevated tumor marker in 17, and suspected bone metastases were detected on BS in 7 patients. Among 10 patients were diagnosed bone metastases, PET/CT detected 10 of 10 bone metastases, however BS detected 7 of 10 bone metastases. PET/CT and BS were not highly concordant in detecting osseous metastases; among 19/28 paired studies (68%), 2 (10%) were positive for metastasis, and 17 (90%) were negative. Nine occurrences (32%) were discordant; of these, 2 of 9 were PET/CT positive and BS negative; 5 of 9 were PET/CT positive and BS equivocal; one case was PET/CT negative and BS equivocal; and one was PET/CT equivocal and BS negative.

Conclusion

This study supports the use of PET/CT for detecting suspected osseous metastases. A large prospective study is needed to determine whether PET/CT could replace bone scintigraphy in detecting suspected bone metastases.
Title: Whole transcriptome analysis of AR+ ER/PR- metastatic breast cancers treated with bicalutamide on TBCRC011

Tiffany A Traina¹, Ayca Gucalp¹, William Polkinghorn¹, Steven Isakoff¹, Sara Tolaney¹, Lisa Carey¹, James Ingle¹, Lisle Nabell¹, Andres Forero¹, Hope Rugo¹, Kimberly Blackwell¹, Minetta Liu¹, Matthew Soloway¹, Lisle Mose¹, Dilip Giri¹, Agnes Viale¹, Clifford Hudis¹, Charles Sawyers¹ and Joel Parker¹. ¹Translational Breast Cancer Research Consortium.

Body: **Background:** The heterogeneity of TNBC includes a subtype that is androgen dependent and whose growth is inhibited by antiandrogen therapy. We conducted a multicenter phase II trial which established the activity of bicalutamide for the treatment of patients (pts) with metastatic ER/PR-negative breast cancer TBCRC011 (Gucalp CCR 2013). We now report results of whole genome, next generation sequencing of the 26 evaluable pts to molecularly classify the study population and to identify potential biomarkers of response to bicalutamide. We hypothesized that those pts whose tumors express increased AR output are most likely to benefit from anti-androgen therapy.

**Methods:** Archival formalin-fixed, paraffin-embedded (FFPE) samples were collected from either primary or metastatic site and RNA was isolated using standard techniques. Whole transcriptome sequencing was performed using the Illumina HiSeq 2000 platform. This data set was compared to that of TCGA, the PAM50 and the Lehmann TN subtypes for molecular classification. Bioinformatic analysis defined a model of AR transcriptional output based on androgen stimulated AR+ ER/PR- breast cancer cell lines (HCC202, SUM185, MDA453) that was applied to the TBCRC011 data set as a predictor of response. Gene set analysis was performed to test secondary hypotheses.

**Results:** 21/26 pts provided adequate gene expression estimates for further analysis. Principal component analysis in comparison to whole transcriptomes from breast cancers in the TCGA show that TBCRC011 tumors associate with the basal like (BL) intrinsic subtype, and this was confirmed by PAM50 classification. Relative AR expression of TBCRC011 cases was similar to that of BLBC in the TCGA. There is a weak but statistically significant positive correlation between AR expression by IHC and transcriptome (r=0.395, p=0.034). An expression-based model of AR activity was derived from AR+ ER/PR- breast cancer cell lines exposed to androgen. TBCRC011 samples segregate with the TCGA samples predicted to be AR responsive by this model. However, the AR output signature did not predict clinical benefit (CR+PR+SD>24 weeks) as defined in TBCRC011. Unexpectedly, by the Lehmann TNBC subtype criteria TBCRC011 tumors were not consistently molecularly classified as luminal AR (BL1-1, BL2-1, Immunomodulatory-5, Luminal AR-4, Mesenchymal-2, Mesenchymal Stem Like-2, Unclassified-6). None of the 4 pts with clinical benefit were classified as BL by the Lehmann model. Gene set analysis revealed that estrogen signal pathways were associated with the number weeks on therapy, and that samples with high scoring AR by IHC exhibited expression patterns of medullary breast cancer.

**Conclusions:** The majority of samples demonstrated expression variation consistent with TCGA basal like breast cancer. Although cell line models predict enrichment of AR activity in both the TCGA basal like and TBCRC011 cohorts, this AR output signature did not predict clinical benefit of bicalutamide. Molecular classification found clinical benefit beyond the luminal AR subtype but exclusive of basal like 1 and 2. Whether IHC or molecular subtype is the optimal biomarker for pt selection for antiandrogen therapy remains uncertain.

Title: Multiple subtypes of triple negative breast cancer are dependent on androgen receptor

Valerie N Barton¹, Nicholas C D'Amato¹, Michael A Gordon¹, Britta M Jacobsen¹ and Jennifer K Richer¹. ¹University of Colorado Anschutz Medical Campus, Aurora, CO.

Body: Triple negative breast cancer (TNBC) constitutes 10-20% of invasive breast carcinomas and has the lowest five-year survival rate. Currently, there are no targeted therapies for TNBC. Recent studies demonstrate that the androgen receptor (AR) is expressed in up to a third of TNBC. AR is highly expressed in the "luminal AR (LAR)" molecular TNBC subtype, but is also present in other TNBC subtypes and may present an opportunity for targeted therapy. We hypothesized that AR+ TNBC critically depend on AR and that AR inhibition will decrease tumor burden in preclinical models of breast cancer. To determine the extent to which AR+ TNBC depend on AR, we inhibited AR activity with the AR antagonist enzalutamide (ENZ) and shRNAs against AR in multiple TNBC subtypes. Treatment with ENZ prevented AR nuclear localization in response to DHT in multiple TNBC cell lines, reduced baseline proliferation in 2D culture (p<0.05), and decreased anchorage independent growth in soft agar (p<0.01). AR knockdown significantly reduced proliferation (p<0.001) and increased apoptosis (p<0.001) compared to cells transduced with a non-targeting control. In addition to reduced proliferation, AR knockdown or treatment with ENZ altered cellular morphology from stellate to round in Matrigel and significantly decreased migration (p<0.05) and invasion (p<0.001) of cell lines spanning multiple TNBC subtypes. Microarray profiling and ELISA of TNBC lines treated with DHT and ENZ suggested that AR regulation of the EGFR ligand amphiregulin (AREG, p<0.05) is a mechanism by which AR influences proliferation, migration and invasion in TNBC. Indeed, treatment with exogenous AREG rescued decreased proliferation, migration and invasion of AR knockdown cell lines (p<0.05). In vivo, ENZ significantly decreased tumor viability (p=0.008) and increased necrosis (p=0.009) in SUM159PT xenografts. Our findings suggest that AR influences both proliferation and invasion of AR+ TNBC cells representing multiple TNBC subtypes and provide promising preclinical data on the efficacy of ENZ in AR+ TNBC. Thus, inhibition of AR by anti-androgens such as ENZ may represent an effective targeted therapy for TNBC.
PIK3CA mutations in androgen receptor-positive triple negative breast cancer confer sensitivity to the combination of PI3K and androgen receptor inhibitors

Brian D Lehmann¹, Joshua A Bauer¹, Johanna M Schafer¹, Christopher S Pendleton¹, Luojia Tang¹, Kimberly C Johnson¹, Xi Chen¹, Justin M Balko¹, Henry Gomez², Carlos L Arteaga¹, Gordon B Mills³, Melinda E Sanders¹ and Jennifer A Pietenpol¹.
¹Vanderbilt-Ingram Cancer Center, Nashville, TN; ²Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru and ³University of Texas MD Anderson Cancer Center, Houston, TX.

Triple negative breast cancer (TNBC) is a heterogeneous collection of biologically diverse cancers, which contributes to variable clinical outcomes. Previously, we identified a TNBC subtype that has a luminal phenotype and expresses androgen receptor (AR+). TNBC cells derived from these luminal AR+ tumors have high frequency PIK3CA mutations. The purpose of this study was to determine if targeting PI3K alone or in combination with an AR antagonist is effective in AR+ TNBC.

Methods: We determined the frequency of activating PIK3CA mutations in AR+ and AR- TNBC clinical cases. Using AR+ TNBC cell lines and xenograft models we evaluated the effectiveness of PI3K inhibitors, used alone or in combination with an AR antagonist, on tumor cell growth and viability.

Results: PIK3CA kinase mutations were highly clonal, more frequent in AR+ vs. AR- TNBC (40% vs. 4%), and often associated with concurrent amplification of the PIK3CA locus. PI3K/mTOR inhibitors had an additive growth inhibitory effect when combined with genetic or pharmacological AR targeting in AR+ TNBC cells. We also analyzed the combination of bicalutamide +/- the pan-PI3K inhibitor GDC-0941 or the dual PI3K/mTOR inhibitor GDC-0980 in xenograft tumor studies and observed additive effects.

Conclusions: While approximately one third of TNBC patients respond to neoadjuvant/adjuvant chemotherapy, recent studies have shown that patients with androgen receptor positive (AR+) TNBC are far less likely to benefit from the current standard of care chemotherapy regimens and novel targeted approaches need to be investigated. In this study, we show that activating PIK3CA mutations are enriched in AR+ TNBC; and, the growth and viability of AR+ TNBC cell line models is significantly reduced after treatment with PI3K inhibitors used in combination with an AR antagonist. These results provide rationale for pre-selection of TNBC patients with a biomarker (AR expression) to investigate the use of AR antagonists in combination with PI3K/mTOR inhibitors.
The prognostic effect of a negative progesterone receptor (PgR) by immunohistochemistry (IHC) in luminal HER-2 negative breast cancer (BC) by age at diagnosis: 10 years follow-up study

Siel JAR Olbrecht¹, Kathleen Van Asten¹, Annouschka Laenen¹, Chantal Remmerie², Wildiers Hans², Floris Guiseppe², Christiaens Marie-Rose², Vergote Ignace² and Neven Patrick². ¹KU Leuven, Leuven, Belgium and ²University Hospitals, Leuven, Belgium.

Background
After menopause, an absent PgR predicts distant metastases (DM) in patients with ER positive HER-2 negative invasive BC. Yamamoto et al. (JCO 2013) questioned the prognostic effect of PR in premenopausal patients, as ovarian estrogens might affect PgR expression. We investigated the effect of PgR on DM free interval (DMFI) and BC specific survival (BCSS) by age at diagnosis as surrogate marker for menopause.

Patients and methods
Retrospective data of consecutive patients with a primary operable ER positive HER-2 negative BC (1/1/2000 - 31/12/2009) were retrieved from our prospectively managed database. Cases that received neo-adjuvant chemotherapy or were operated in another hospital, were excluded. BC with missing values for PgR, grade or lymph node status and/or lost to follow-up were excluded in some subgroup analyses. A multivariate (MV) competing risk model for DMFI and BCSS was established considering age at diagnosis (age ≤50 yrs vs >50 yrs), PgR status, tumor grade (1-3), tumor size (mm) and lymph node status (neg/pos). Steroid receptors were considered positive if ≥1% stained on IHC. Differential prognostic effects of these variables according to PR or age were tested by means of interaction effects. Only significant interactions were included.

Results
We included 3326 BCs (8 with missing PgR status); 2911 (87.5%) PgR positive [870 (26.2%) ≤50 yrs and 2041 (61.4%) >50 yrs] and 407 (12.5%) PgR negative [68 (2.0%) ≤50 yrs and 339 (10.2%) >50 yrs]. In absolute numbers and compared to PgR positive BCs, PgR negative cases >50yrs had more DM if grade 3 and more BCSS for all grades. In BC ≤50 yrs these differences were not found, but only 7.2% were PgR negative (Tab.1). Results from the MV models showed a significant interaction with PgR on DMFI and BCSS (respectively p=0.01 and p=0.002) resulting in higher risk of DM (HR, 1.9; 95% CI, 1.4-2.7; p=0.001) and BCSS (HR, 2.4; 95% CI, 1.6-3.7; p<0.001) when PgR was absent for BCP >50 yrs. This difference in DMFI and BCSS according to PgR status was not found in BC ≤50 yrs (Tab.2).

**Conclusions**

A negative PgR is only prognostic for DMFI and BCSS in women aged >50 at diagnosis. There was no difference of PgR for these endpoints in patients ≤50 yrs at diagnosis but PR negativity is rare in this age group.
Title: Invasive lobular carcinoma cell lines utilize WNT4 signaling to mediate estrogen-induced growth

Matthew J Sikora¹, Amir Bahreini¹, Caroline M Alexander² and Steffi Oesterreich¹. ¹University of Pittsburgh, Pittsburgh, PA and ²University of Wisconsin, Madison, WI.

Body: Invasive lobular carcinoma (ILC) is a histological subtype of breast cancer representing 10-15% of newly diagnosed breast tumors. Over 90% of ILC are ER-positive, however, endocrine response and estrogen signaling are not well described in ILC. Retrospective analyses suggest that ILC patients treated with endocrine therapy have poorer outcomes than similar invasive ductal carcinoma (IDC) patients, and that ILC patients may not benefit from adjuvant tamoxifen. Additionally, we recently identified ILC-specific ER-target genes and de novo tamoxifen resistance driven by ER in ILC model systems. Based on these observations, we hypothesize that ILC-specific signaling pathways driven by ER mediate growth and endocrine resistance in ILC cells.

Among ILC-specific estrogen-regulated genes in the ILC cell lines MDA MB 134VI (MM134) and SUM44PE (SUM44), Wnt signaling genes were highly differentially expressed. The secreted ligand WNT4 was the most strongly estrogen-induced gene in ILC cells. The frizzled receptor FZD7 is also strongly induced in ILC cells, but only transiently induced in the ER-positive IDC cell line MCF-7. Among IDC cell lines, either WNT4 or FZD7 is over-expressed in ER-positive or ER-negative cells, respectively. Conversely, MM134 and SUM44 over-express both WNT4 and FZD7. Also, we identified an ILC-specific ER binding site at WNT4; located in intron 1, this site contains a predicted estrogen response element. Direct WNT4 regulation and parallel regulation of pathway genes suggests that ER controls a WNT4 signaling pathway in ILC cells. In samples from the Cancer Genome Atlas, WNT4 and FZD7 are each over-expressed in ER-positive ILC versus IDC; co-expression is also enriched only in ILC. These observations suggest that a WNT4 signaling pathway may be specifically active in ILC.

To assess whether WNT4 is necessary for estrogen-induced growth, we used siRNA to knock down WNT4. Using either of two siRNAs, WNT4 knockdown completely blocks estrogen-induced growth in ILC cells, but not IDC cells. Consistent with this, WNT4 knockdown abrogated estrogen-regulation of a subset of ER-target genes in MM134 cells; induction or repression was inhibited by WNT4 knockdown prior to estrogen treatment. Thus, a subset of estrogen-induced gene expression changes is mediated by WNT4 signaling. Though Wnt signaling typically acts via the canonical, β-catenin-dependent pathway, we observed that β-catenin signaling is dysfunctional in ILC cells. Additionally, WNT4 over-expression or recombinant protein cannot activate canonical Wnt signaling in breast cancer cell lines. This suggests that WNT4 signaling mediates estrogen-induced growth in ILC cells via a novel non-canonical signaling pathway.

Wnt signaling pathway genes including WNT4 are uniquely regulated in ILC cell lines, and are over-expressed in ILC tumors, suggesting that a WNT4-driven pathway may be active specifically in ILC. WNT4 is necessary for estrogen-mediated growth in ILC cells, and likely signaling via a novel non-canonical signaling pathway. Targeting WNT4 signaling represents a novel approach to modulate endocrine response specifically for ILC patients. Future studies will focus on identifying the signaling pathway controlled by WNT4 in order to identify novel therapeutic targets.
Title: Inhibiting androgen receptor nuclear localization decreases estrogen receptor (ER) activity and tumor growth in ER+ breast cancer

Nicholas C D'Amato¹, Britta M Jacobsen¹, Dawn R Cochrane¹, Nicole S Spoelstra¹, Beatrice L Babbs¹, Anthony Elias¹ and Jennifer K Richer¹. ¹University of Colorado Anschutz Medical Campus, Aurora, CO.

Body: Background: Androgen receptor (AR) is widely expressed in breast tumors, but the role of AR in estrogen receptor (ER)+ tumors is controversial. In the absence of estradiol (E2), dihydrotestosterone (DHT) increases growth of ER+ breast cancer cells in vitro and in vivo. Anti-androgens such as bicalutamide (Bic) and enzalutamide (ENZ) inhibit this DHT-mediated proliferation. Surprisingly we have found that ENZ, which impairs nuclear entry of liganded AR, also inhibits E2-mediated proliferation of ER+ breast cancer cells, while Bic does not.

Hypothesis: We hypothesize that nuclear localization of AR is necessary for maximal E2-mediated proliferation in ER+/AR+ breast cancer cells, and targeting AR with ENZ or other agents that impede AR nuclear entry or cause AR degradation will inhibit growth of ER+/AR+ human breast cancer cell lines and decrease tumor burden in preclinical models.

Methods: ER+/AR+ MCF7, BCK4, and ZR-75-1 cells were treated with E2 plus or minus ER and AR antagonists and proliferation was measured by crystal violet staining or Incucyte live cell imaging. Nuclear AR was assessed by immunocytochemistry or nuclear/cytoplasmic fractionation. For in vivo experiments, 1x10^6 luciferase-expressing MCF7 cells were injected into the mammary fat pad of nu/nu mice and tumor growth monitored by caliper and IVIS imaging.

Results: ENZ blocked E2-induced proliferation and showed synergistic activity with the ER antagonists 4-hydroxy-Tamoxifen (OH-Tam) and Fulvestrant (Fulv) in vitro. E2-induced expression of ER target genes including PR and SDF1 was also inhibited by ENZ, but not by Bic. Similarly, AR knockdown decreased baseline and E2-induced proliferation of MCF7 cells and E2-induced ER target gene expression. Both DHT and E2 treatment induced nuclear translocation of AR, which was decreased by ENZ. Nuclear translocation of AR in response to E2 occurs only in ER+ cell lines, further supporting a role for nuclear AR in E2-induced ER activity. In vivo, ENZ inhibited E2-induced growth of MCF7 tumors as effectively as Tamoxifen (Tam), and the combination of ENZ plus Tam was more effective than either drug alone. ENZ also inhibited growth of Tam-resistant MCF7 cells in vitro.

Conclusions: Our results suggest that nuclear localization of AR plays a previously-unrecognized role in E2-mediated ER activity in ER+/AR+ breast cancer cells. Because of its ability to inhibit nuclear entry of liganded AR, ENZ may serve as an effective therapeutic in ER+/AR+ breast cancers. Importantly, ENZ may be particularly useful in combination with current anti-estrogen therapies (Tam or Fulv) since it affects ER, but via an indirect mechanism acting through AR. ENZ may also be effective in tumors resistant to ER-directed therapy based on in vitro data and published clinical data indicating that many such tumors express more AR protein than ER.

**Title:** Androgen receptor expression in triple negative breast cancer

Hannah Gilmore¹, Vinay Varadan¹, Nicole Williams¹, Cheryl L Thompson¹, Stephanie Kim¹, Peter Hsu¹, Kristy Miskimen¹, Aditi Palkar¹, Shaveta Vinayak¹, Robert Lindner² and Lyndsay Harris¹. ¹Case Western Reserve University, Cleveland, OH and ²Yale University, New Haven, CT.

**Body:** Background: Patients with androgen receptor (AR) positive triple-negative breast cancer (TNBC) may derive a significant benefit from anti-androgen therapy. While AR positivity is often defined by protein expression by immunohistochemistry (IHC), the benefit of anti-androgen therapy in patients who have the Luminal Androgen Receptor (LAR) molecular subtype as defined by genomic profiling is unclear. Our aim was to study the clinical, pathologic and molecular profiles of AR+ tumors by IHC in a diverse set of TNBC.

Methods: Tissue microarrays from two separate, well-annotated institutional cohorts (Case Western Reserve University, Yale University) of early-stage TNBC were evaluated for AR expression by IHC (clone SP107, Ventana Benchmark Ultra). AR positivity was defined as greater than or equal to 10% staining in tumor nuclei. AR expression was correlated with clinical and pathologic features such as age, race, grade, and stage within and between the two cohorts. Gene expression was analyzed with the DASL assay (Illumina) on RNA extracted from formalin-fixed paraffin-embedded material using the Ambion RecoverAll kit (Applied Biosystems AM1975). Pietenpol TNBC molecular subtypes were calculated using the online TNBC type tool. Co-expression of AR with other hormone-related proteins including gross cystic disease fluid protein-15 (GCDFP-15, clone EP1582Y, Ventana Benchmark Ultra) and GATA transcription factor 3 (GATA3, clone L50-823, Bondmax Leica) were also assessed.

Results: Overall, 22% of cases (n=192) were AR+ by IHC. There was no association between AR expression and age, race, grade or stage within or between the two cohorts. Gene expression data was available on 88 tumors with AR staining results and demonstrated that AR positivity by IHC was not exclusive for the TNBC LAR molecular subtype. Three of five (3/5) tumors that were classified and LAR were in fact AR+ by IHC. Tumors that were AR+ by IHC were also identified in the basal-like 2 (BL2), mesenchymal stem-like (MSL), immunomodulatory (IM), and unstable molecular TNBC categories with low frequency. Notably, of cases that were rejected as ER+ by gene expression profiling despite being clinically TNBC, three of five (3/5) were in fact AR+ by IHC. Examination of other hormone-related proteins in a subset of these patients revealed that AR expression was significantly associated with GCDFP-15 expression (p=0.0007) and was borderline significant for GATA3 expression (p=0.068).

Conclusions: AR protein expression levels by IHC were similar in two separate institutional archival cohorts of TNBC and did not correlate with age, race, grade or stage. Comparison of AR IHC data with genomic data suggests that the AR+ phenotype is not unique to LAR subtype of TNBC by gene expression profiling. AR protein expression may be seen in clinically TNBC patients who have a more luminal subtype as evidenced by co-expression of GCDFP-15 and GATA3. Our results suggest that AR staining by IHC may be necessary to capture all patients who may benefit from anti-androgen therapy.
Title: Discordance with estrogen receptor alpha status estimated by immunohistochemical and immunofluorescent method associated with flowcytometry in breast cancer tissue

Maria Rodionova1, Tatiana Bogush1, Evgeniy Dudko1, Shestakova Elena1, Bogush Elena1, Vorotnikov Igor1 and Davidov Michael1. 1N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation.

Body: Background.
Estrogen receptors alpha (ER) are one of the most important breast cancer prognostic and predictive markers but routine used immunohistochemical (IHC) method does not allow accurate ER determination because of semi quantitatively assay and tumor heterogeneity. That is why in studying of different tissue paraffin blocks the molecular diagnosis is often controversial. To avoid these problems an accurate quantitative immunofluorescent method associated with flowcytometry (FC) that allows the investigation up to 10,000 or more cells from several parts of surgical breast cancer samples was developed by us and used for the comparison of IHC and FC approaches in study of ER expression.

Materials and methods.
55 breast cancer surgical biopsy specimens were analyzed by FC. Single-cell suspensions were incubated with primary monoclonal antibody (SP1, ab27614) overnight and with secondary DyLight650-conjugated antibody (ab98510, Abcam) for 1.5h. DNA-specific dye Hoechst 33258 (Sigma) was used for the separation of debris and cellular aggregates. Cell fluorescence data were analyzed with FlowJo 7.6.1 software and Kolmogorov-Smirnov statistical approach. The routine IHC indexes of ER status were obtained from the history of cases of the same patients (pts). The pts were divided into 3 groups according to the levels of ER expression: ER–, low ER+and high ER+ that correspond respectively to IHC – <1%; 1-40%; >40% and to FC – <15%; 15-40%; >40%.

Results.
1. Approximately the same proportion of ER– and ER+ tumors, about 30 and 70% respectively, was detected using either IHC or FC method but discordance with the results of individual pts was revealed. 2. Differences in repeated FC estimations of ER status in the same tumors did not exceeded 10%.
3. Differences between IHC and FC indexes in the same tumors were significant. It was demonstrated that, when the tumors estimated as ER– by IHC were analyzed with FC, about 40% of cases were classified as ER+ tumors, and opposite, in the group of tumors estimated as ER+ by IHC, 30% were determined as ER– tumors by FC.
4. There were small differences between IHC indexes in high level of ER+ group (65-100%) but in this group of tumors analyzed by FC there were 15% of ER– ones, 35% –ER+ with low and 50% – ER+ cases with high level of the marker expression. So, accurate quantitative indexes of ER+ in IHC and FC groups were similar in half of cases only.

Conclusion.
Discordance with breast cancer ER status analyzed either with IHC or FC methods in various tissue paraffin blocks as well as between paraffin blocks of the same surgical sample supports a real contribution of tumor heterogeneity in inexactitude of molecular diagnosis of ER breast cancer status. Solely IHC investigation is not accurate enough for the final conclusion and repeated analysis of different tumor paraffin blocks using IHC in association with FC investigation of the same patient surgical tumor sample is needed to characterize ER tumor status in a more precise way.

**Body:** Background: Several lines of evidence suggest that progesterone signaling is important in the breast cancer development, particularly in young women. Therefore, we sought to establish the effects of the antiprogestin CDB4124 (telapristone), and to identify PR related signature genes in hormone receptor positive (ER+ PR+) breast cancer cells.

Methods: The PR expressing breast cancer cell line T47D was used to evaluate responses to PR ligands (P4, MPA and R5020, 10nM) alone or in combination with estradiol (E2, 1nM). The effects of the antiprogestin CDB4124 (0.1 or 1µM) were tested using varying hormonal conditions. The effect on (a) PRE promoter activity by dual luciferase assay; (b) cell proliferation using the MTT assay; (c) cell cycle by flow cytometry; (d) determination of gene expression signatures related to active PR responses. For the gene array experiment, cells were treated with either vehicle or R5020 (10nM) or R5020 (10nM) plus CDB4124 (1µM) in triplicate for 24hr. Total RNA was isolated and converted to cDNA and human Illumina chip microarray was performed. Data obtained from the microarray was further analyzed by Metacore Gene GO and Ingenuity Pathway Analysis. Real time PCR was performed in triplicate to confirm the expression of those genes related to the cell cycle and proliferation. ANOVA analysis and post-hoc Sidak test were used to determined the statistical significance of the data.

Results: The PRE reporter activity resulting from P4, MPA and R5020 stimulation was inhibited by 80-90% in the presence of CDB4124 at 10 to 1000nM (p< 0.001). Cell proliferation was increased by PR ligands (P4, MPA and R5020) in the presence of E2; the addition of CDB4124 caused 50% inhibition of proliferation (p< 0.01) at 72 hours. Cell cycle analysis of T47D cells treated with P4, MPA and R5020 alone or in combination with E2 showed significant increases in S and G2/M phase and decreases in G0/G1. These were blocked by CDB4124 at 0.1 or 1.0µM (p<0.05 for all). Gene GO metacore analysis of genes identified in the microarray revealed significant enrichment of cell cycle pathways (FDR, p< 1.0X10-11 ) upon treatment with R5020. The addition of CDB4124 to R5020 treated samples showed inhibition of the same cell cycle pathways (FDR,p<1.0X10-14). A 16-gene panel related to G2/M phase of cell cycle was selected based on >1.5 fold upregulation (p<0.001) during treatment with R5020,10nM and blockade by CDB4124. Real time PCR confirmed upregulation of this 16 gene panel ≥2.0 (p<0.05) in the presence of PR ligands alone or in combination with E2 which were significantly blocked by the addition of CDB4124.

Conclusion: These data demonstrate that PR mediated cell proliferation occurs upon treatment with three different ligands of PR (P4, MPA and R5020); that PR actively engages key genes involved in the G2/M phase of the cell cycle to drive proliferation of ER+ and PR+ cells; and that the antiprogestin, CBD4124 is a potent transcriptional inhibitor for blockade of PR mediated cell proliferation in hormone receptor positive breast cancer cells.

Title: Thyroid hormone up-regulates estrogenic and pro-carcinogenic signaling, inducing a basaloid and more motile phenotype in only steroid receptor positive breast cancer cells

Ann D Thor¹, Zeying Fan¹, Reema Wahdan-Alaswad¹ and Susan M Edgerton¹. ¹University of Colorado Anschutz Medical Center, Aurora, CO.

Body: Background: Co-morbidity of thyroid disease and breast cancer has been recognized for over a century. Up to two-thirds of women with breast cancer have clinical or occult thyroid disease, as compared to one fifth of unaffected females. Thyroid disease typically proceeds breast cancer by at least a decade, and many (nearly half) are on long term thyroid hormone supplementation at the time of diagnosis. The exogenous administration of thyroid hormone, for hypothyroidism or status post thyroidectomy for neoplasia, has been associated with an increased risk of breast cancer and in some studies, a worse prognosis. Causality, however, has been controversial.

Results: We studied over 800 consecutive node negative invasive breast cancer patients diagnosed between 1976 and 1993 from a single institution. Of these, 92% were chemo-naive and only 14% received tamoxifen, reducing interactions with treatment for the study design. We showed untoward significant interactions with both univariate and multivariate analyses, between thyroid hormone supplementation, disease free and disease specific survival only in patients with steroid receptor positive tumors. These interactions were strongest in pre-menopausal, as compared to post-menopausal patients. We thus hypothesized that thyroid hormone (TH), either indirectly or directly, promoted carcinogenesis via the steroid receptors (SR) for estrogen and/or progesterone and have interrogated mechanisms of these interactions in vitro. Estrogen (E2) induce significant cellular proliferation, whereas TH alone (at concentrations of T₄ 1 x 10⁻⁶:T₃ 2.5 x 10⁻⁷ M) induced only mild cell proliferation in SR⁺ (MCF-7 and T47D), but not SR⁻ breast cancer cell lines (MDA-MB-468 and SKBR3). In contrast, TH induced significant proliferation in SR⁺ cells at significantly lower doses (down to T₄ 1 x 10⁻¹²: T₃ 2.5 x 10⁻¹³ M) if administered with low dose estrogen (E2: 1 x 10⁻¹⁰). These mitogenic effects were demonstrated by MTS and DNA quantification assays, as well as flow cytometry, which revealed the induction of G2/M arrest and an increase in the percentage of cells in S phase with TH alone (at higher doses) or TH + E2 (at lower doses). Tamoxifen partially mitigated the pro-growth effects of TH + E2, whereas ICI 182,780 completely abrogated these effects. Using Western blots we have shown that that TH (with or without E2) upregulated ERα expression and activation, Cyclin A, B,D1, and E, E2F1, MAPK/ERK1/2 but not AKT signaling. TH +/- E2 also promoted clonogenicity, motility, a more basal phenotype (CD24+/CD44+) and mammosphere formation in cells grown under non-adherent conditions.

Conclusions: We have demonstrated in Stage I breast cancer patients with minimal systemic treatment, that the administration of TH was associated with a significantly shortened disease free and disease specific survival, only in patients whose tumors expressed SR. TH administered to SR⁺ cell lines, particularly when co-administered with E2 at therapeutic/physiologic doses, upregulates and activates ER, cell proliferation, a more aggressive and motile basaloid phenotype.
Title: Pathological and molecular effects of lack of PR expression in ER positive breast tumors

Rachel E Ellsworth³, Allyson L Valente¹, Matthew T Hueman² and Craig D Shriver². ¹Windber Research Institute, Windber, PA; ²Walter Reed National Military Medical Center, Bethesda, MD and ³Henry M Jackson Foundation for Military Medicine.

Body: Background: Evaluation of hormone receptor status is standard in breast cancer diagnosis; however, prognosis and treatment decisions are frequently based on the status of the estrogen receptor (ER) but not the progesterone receptor (PR). To determine how PR status affects etiology and outcome of ER positive tumors, pathological and molecular characteristics of ER+PR+ and ER+PR- tumors were assessed.

Methods: ER and PR positivity were defined as >10% staining and all patients with ER+PR+ and ER+PR- were identified. Differences in pathological characteristics were evaluated using Chi-square tests with P<0.05 defining significance. RNA was isolated from primary tumor cells after laser-microdissection and hybridized to U133A 2.0 arrays. Gene expression data was analyzed by ANOVA using a false-detection rate <0.5 and >2.0-fold difference to define significance.

Results: Of the 1,139 ER+ tumors, 21% were PR-. Age at diagnosis, ethnicity, tumor size, lymph node and Ki67 status did not differ between groups; however, patients with PR- tumors were significantly more likely to be diagnosed at an advanced stage, with high-grade, HER2 positive tumors, and more likely to die of disease. Thirty genes were differentially expressed including significantly higher expression levels of APOBEC3B and significantly lower expression of GREB1, MAPT and SCUBE2.

Discussion: Expression of PR significantly alters tumor biology and clinical outcomes of ER positive tumors. Genes with altered expression in PR negative tumors are associated with more aggressive characteristics, such as increased invasion, kataegis, regulation of ER and response to tamoxifen. Thus, PR status is critical in the diagnosis and treatment of patients with ER positive breast tumors.
Title: Progesterone receptor activation downregulates GATA3 by transcriptional repression and increased protein turnover promoting breast tumor growth

Franco Izzo¹, Florencia Mercogliano¹, Leandro Venturutti¹, Gloria Inurrigarro², Mauro Ezequiel Cenciarini¹, Roxana Schillaci¹, Leandro Cerchietti³, Patricia Virginia Elizalde¹ and Cecilia Jazmín Proietti¹. ¹Instituto de Biología y Medicina Experimental, Buenos Aires, Argentina; ²Hospital Mater Dei, Buenos Aires, Argentina and ³Weill Cornell Medical College, New York, NY.

Body: The master transcription factor GATA3 is involved in mammary gland development and is crucial for the maintenance of the differentiated status of luminal epithelial cells. The role of GATA3 in breast cancer as a tumor suppressor has been widely established, although insights into the mechanism of GATA3 expression loss are still required. In the present work, we demonstrate that progestin-activated progesterone receptor (PR) reduces GATA3 expression through regulation at the transcriptional and post-translational levels in breast cancer cells. In the former mechanism, the histone methyltransferase enhancer of zeste homolog 2 (EZH2) is co-recruited with activated PR to a consensus progesterone response element in GATA3 proximal promoter, increasing the tri-methylation of lysine 27 of histone 3 (H3K27me3) and inducing chromatin compaction, resulting in decreased GATA3 mRNA levels. This transcriptional regulation is coupled with increased GATA3 protein turnover through progestin-induced GATA3 phosphorylation at serine 308 followed by 26S proteasome-mediated degradation. Both molecular mechanisms converge to accomplish decreased GATA3 expression levels in breast cancer cells upon PR activation. In addition, we demonstrated that decreased GATA3 levels are required for progestin-induced upregulation of cyclin A2, which mediates the G1 to S phase transition of the cell cycle and was reported to be associated with poor prognosis in breast cancer. Finally, we showed that downregulation of GATA3 is required for progestin stimulation of both in vitro cell proliferation and in vivo tumor growth.
Title: Prognostic impact of Her2 and hormone receptor expression in inflammatory breast cancer: A SEER database analysis

Anna Maria Affan¹, Babu P Mohan¹, Kali Praveena Iruku¹ and Keyvan Ravakhah¹. ¹St Vincent Charity Medical Center, Cleveland, OH.

Body: INTRODUCTION: Inflammatory breast cancer (IBC) is known to be one of the most aggressive forms of breast cancer. Patients with IBC generally present with early metastases and are frequently resistant to conventional chemotherapies. By using the SEER database, we explored the clinical relevance of Her2 and hormone receptor (HR) expression in IBC tumors and the possible impact it may have on management.

METHODS: Data for patients with IBC was extracted from the Surveillance, Epidemiology, and End Results (SEER 18) database from 2010 to 2011. A sub-analysis with the available receptor status data for the same period was analyzed using CanSurv survival software. The Actuarial method was used to construct survival curves according to the following receptor variables; Her2+/HR+, Her2+/HR-, Her2-/HR+, and triple negative IBC groups. Demographic data including race and age was also extracted.

RESULTS: Of 354 cases of IBC reported, 5% (n=18) of the tumors were Her2+/HR+, 7.9% (n=28) Her2+/HR-, 15.3% (n=54) Her2-/HR+, and 12.4% (n=44) triple negative. Highest 1 year survival rates were seen in those patients with Her2-/HR+ tumors at >95% while Her2+/HR+ had the lowest 1 yr survival rates at 65%.

Caucasian patients above 30 years represented the highest racial group at approximately 70% (n=105). Analysis of this subgroup showed 38% (n=40) of these patients having HER2-/HR+. Despite more than 75% (n=33) of these patients presenting with advanced disease, the 1 year survival remained highest among all the receptor combinations analyzed. This observation held true across all racial groups even with those population numbers for IBC being less.

CONCLUSION: The Her2-/HR+ receptor combination group showed the greatest 1 year relative survival when compared to the other groups. These results suggest that HR expression in the absence of Her2 is associated with an increased survival. This can play a role in the management of IBC by incorporating hormonal therapy into the treatment protocols for patients with IBC to possibly improve survival.
Title: Ethinylestradiol treatment downregulates ER and upregulates PgR; Immunohistochemical analysis in postmenopausal breast cancer tissues after prior long-term estrogen-deprivation therapy

Hirotaka Iwase¹, Yoko Omoto¹, Takashi Takeshita¹, Mutsuko Yamamoto-Ibusuki¹, Mitsuhiro Hayashi¹, Aiko Sueta¹, Saori Fujiwara¹ and Yutaka Yamamoto¹. ¹Kumamoto University, Kumamoto, Japan.

Body: **Background:** Estrogen receptor (ER) positive breast cancer can often be treated by hormone therapy; however a certain population of ER-positive patients becomes resistant to hormone therapy after long-term hormone treatment. Ethinylestradiol (EE2) is a derivative of estrogen which has shown promising effects on in these patients. **Methods:** We successfully obtained tissue samples from 6 patients undergoing EE2 treatment and examined 13 well-known breast cancer-related factors by analyzing their gene expression and by immunohistochemistry. Of the 6 patients, 5 responded but one patient did not. **Results:** Before EE2 treatment, staining for both ER and androgen receptor (AR) was strong in the nucleus, with weak staining of the progesterone receptor (PgR). EE2 treatment significantly down-regulated ER and up-regulated PgR while nuclear and cytosolic AR were oppositely down- and up-regulated, respectively, by EE2. Cytosolic staining of BRCA1 was significantly up-regulated by EE2 whereas nuclear staining tended to decrease. Individual comparisons suggested less induction of PgR and decreasing AKT but increasing pAKT in the non-responder following EE2 treatment. **Conclusion:** Our observations revealed that EE2 activated ER downstream genes, although it did not stimulate cell growth. This suggests that hormone resistant cells might receive growth signals from a non-genomic pathway and this may be reflected in their sensitivity to EE2 treatment.
Title: Estrogen receptor β agonists reduce breast cancer tumor growth in syngeneic mouse models

Cathy Samayoa¹, Naveen K Krishnegowda¹, Ratna K Vadlamudi¹ and Rajeshwar R Tekmal¹. ¹University of Texas Health Science Center, San Antonio, TX.

Body: The estrogen receptors (ER) play a significant role in breast cancer, with the majority of breast cancers expressing estrogen receptor alpha (ERα) and depending on its signaling. ERα has proliferative function, however, estrogen receptor beta (ERβ) has anti-proliferative functions. Recently, several selective ERβ agonists have been identified. The objective of this study was to determine the effectiveness of ERβ agonists in inhibiting the growth of distinct breast cancer cells both in-vitro and in-vivo, and to determine the mechanisms involved. The mouse mammary tumor cell lines, D2A1 and MM51, express both ERα and ERβ. Specifically D2A1 cells are dependent on estrogen for growth and have increased expression of aromatase. Additionally, D2A1 cells are very aggressive and highly metastatic; representing a good model of breast cancer progression. MM51 cells are Her2/neu positive and are an adequate model to study the crosstalk between growth factors and ER signaling. Syngeneic mouse tumor models were used to incorporate an intact immune system which plays a role in the tumor’s microenvironment. Our in-vitro studies demonstrate that ERβ agonists significantly inhibit cell growth in a dose dependent manner. Our syngeneic studies show that, in-vivo, ERβ agonists effectively reduce tumor volume and inhibit tumor progression. This study reveals that in addition to acting on ERβ, these agonists reduce the expression of ERα at both the mRNA and protein level, therefore modulating the ratio of ERα to ERβ. Additionally, treatment with ERβ agonists results in increases apoptosis through increased p53 expression, and cell cycle arrest through p27 and cyclin D1. Together, these studies demonstrate the therapeutic potential of ERβ agonists for the treatment of breast cancer.
**Title:** Triple negative breast carcinomas clinical and pathology associated with androgen receptor expression

Marcia Graudenz¹, Mirian Pedron¹, João Maximiliano¹, Diego Uchôa¹ and Sídia Jacques¹. ¹UFRGS, Faculty of Medical Sciences, Porto Alegre, Rio Grande do Sul, Brazil.

**Body:**

**INTRODUCTION:** Triple negative breast carcinomas (TNBC) are a heterogeneous group of tumors characterized by poor patient survival and lack of targeted therapies. Androgen receptor (AR) has been described in TNBC but the prognostic impact of the expression in this subgroup of tumors is not clear. **OBJECTIVE:** To investigate the association of AR expression status by immunohistochemistry in TNBC cases with clinical (age, survival) and pathological variables (tumor size, tumor grade).

**METHODS:** 62 TNBC were analyzed by automated immunohistochemistry for androgen receptor. Immunohistochemistry was scored by two investigators and biomarker expression was assessed by H-Score (intensity plus the percentage of staining). Kaplan–Meier was used to evaluate overall survival, where differences in distributions were evaluated based on marker expression. **RESULTS:** 26% of TNBC were AR-positive (n=16) and 74% AR negative (n=46). All AR-positive cases occurred in women ≥ 40 years, while 13% of AR-negative cases were seen in women ≤ 40 years. 93% (52/56) of all TNBC were infiltrating ductal carcinomas of no special type (ICNST) and 14/15 (93%) of AR-positive cases were ICNST. Tumor size varied from 2-4.9 cm in the majority of AR-positive cancers (n=8/13; 62%). 60% (n=9/15) of AR-positive cases showed histological grade 3 tumors, followed by 27% of grade 2 tumors. No differences were observed between AR-positive and AR-negative patients when compared for age, tumor size, tumor grade and tumor type (all p>0.17). AR immunohistochemical positivity was also not associated with better overall survival (p=0.737, N = 51) or disease-free survival (p = 0.552; N = 45) in TNBCs. **Conclusion:** From the prognostic point of view, AR immunoreactivity has been associated with better overall patient survival. This result was not confirmed in our series. This could be related to the relatively small series of analyzed samples and to the low prevalence of AR-positive cases in this specific breast cancer subtype. Further studies with bigger samples are needed to investigate this biomarker in TNBC.

**Key Words**

Breast Cancer, Immunohistochemical markers, Androgen receptor Triple negative.
**Title:** Development for clinical utility of a validated predictive test of clinical response to aromatase inhibitors

Arran K Turnbull¹, Laura Arthur¹, Victoria Webber¹, Jeremy Thomas¹, Charlotte Heerlyn¹, Phoebe Thornton¹, Anita Dunbier², Mitch Dowsett³, Lorna Renshaw¹, Andrew H Sims¹ and J Michael Dixon¹. ¹University of Edinburgh, Edinburgh, United Kingdom; ²University of Otago, Otago, Dunedin, New Zealand and ³Institute of Cancer Research, London, London City, United Kingdom.

**Body:** Background: Aromatase inhibitors (AIs) have an established role in the treatment of estrogen receptor alpha positive post-menopausal breast cancer. Response rates are only 50-70% even in patients with ER-rich cancers in the neoadjuvant setting and are lower in advanced disease. Recently we developed and validated a microarray-derived 4-gene test to predict response to AIs in the neoadjuvant setting. Whole-genome expression analysis is impractical for clinical utility. There is a need to translate and validate any test utilising clinically accessible and reproducible material and technologies such as polymerase chain reaction (PCR) and immunohistochemistry (IHC).

Methods: The original microarray experiment used pre- and on-treatment (at 14 days and 3-months) biopsies from 89 post-menopausal women with ER-rich breast cancer receiving 3 months of neoadjuvant letrozole. Dynamic response was based on periodic 3D ultrasound measurements performed during treatment. The derived 4-gene model was independently validated in a cohort of 44 post-menopausal women with ER-rich breast cancer treated with neoadjuvant anastrozole [table 1]. RNA was extracted from the original biopsies for RT-qPCR analysis using validated primers for the 4 genes with SYBR-green technology normalised to the geometric mean of 3 housekeeping genes. Matched formalin-fixed paraffin embedded (FFPE) tissue sections were used for IHC with optimised antibodies against 3 of the 4 proteins (where validated antibodies were available) using Envision technology.

Results: PCR: Microarray and PCR expression levels for each of the four genes were well correlated (Pearson r=0.87-0.65, p<0.0001). Application of the 4-gene model, using PCR expression levels, to a cohort of patients from the initial training set (n=26) resulted in prediction of response with 96% accuracy [table 1]. IHC: stained FFPE tissue sections for proteins corresponding to the 3 most informative genes in the model were independently scored using a histoscore approach (0, 1+, 2+, 3+) in a sample of patients where tissue was available (n=28). Increasing histoscores were associated with increasing gene expression for all 3 proteins (r=0.72, 0.73, 0.60). Each sample was assessed and histoscore determined, then a positive and negative cut-off histoscore was determined for each protein to maximise response prediction. This was then applied to an IHC decision tree, based on the original 4-gene microarray model, and was able to categorise patients as responsive or non-responsive with 89% accuracy.

Sensitivity and specificity of model in training (microarray, PCR, IHC) and validation datasets (microarray). PPV/NPV = postivie/negative predictive value.

**Conclusion:**
- A 4 gene model has been developed and validated to predict response to neoadjuvant aromatase inhibitors.
- This model has been shown to work with a high degree of accuracy using both PCR and IHC technologies. Further independent validation is currently underway.
- This new test has the potential to predict accurately the benefit of endocrine therapy and has huge potential clinical value.
Title: Global characterisation of the SRC-1 transcriptome and rational drug design results in the identification of a novel peptide targeting ADAM22 in endocrine resistance

Jarlath C Bolger¹, Damian McCartan¹, Damir Vareslija¹, Ailis Fagan¹, Christopher Byrne¹, Marie McIlroy¹, Peadar O’Gaora², Arnold D Hill¹ and Leonie S Young¹. ¹Royal College of Surgeons in Ireland, Dublin, Ireland and ²University College, Dublin, Ireland.

Body: In spite of therapeutic advances, up to 25% of luminal breast cancers will eventually develop resistance to endocrine therapy and develop metastatic disease. The underlying mechanism causing ER-positive, steroid responsive tumours to develop a resistant, metastatic phenotype remains unresolved. Previous work from our group and others has identified the P160 protein SRC-1 as a significant predictor of recurrence on endocrine therapy. The purpose of this study is to further examine downstream SRC-1 targets in the context of endocrine resistant breast cancer.

We adopted a global approach to define the transcriptional targets of SRC-1. SRC-1 ChIP sequencing in endocrine resistant luminal B breast cancer cells was combined with SRC-1 gene expression array analysis. This identified a number of pathways significantly elevated following tamoxifen treatment, including a number involved in cellular adhesion. From these pathways, A Disintegrin And Metalloproteinase-22 (ADAM22) was selected for further study.

Knockout studies confirmed ADAM22 as a tamoxifen dependent SRC-1 target gene. Functional assays including migration, three dimensional cell culture and adhesion independence growth assays confirmed a role for ADAM22 in promoting a migratory, aggressive phenotype. Samples from two separate TMAs comprising over 1,000 patients confirmed that ADAM22 is associated with poor disease free survival in breast cancer patients.

LG1 is a naturally occurring neuropeptide which acts on an inhibitory manner on ADAM22 in the central nervous system. Using molecular modelling, a novel peptide mimetic targeting the disintegrin binding domain of ADAM22 was designed. Treatment with this peptide mimetic restored endocrine resistant cells to a less aggressive, sensitive phenotype, similar to the effect seen with knockdown of ADAM22. Moreover in an endocrine resistant xenograft model, treatment with the LG1 mimetic significantly reduced primary and metastatic tumour burden in tamoxifen treated animals.

We have used next-generation sequencing techniques to identify a novel therapeutic target in endocrine resistant, metastatic breast cancer. Rational drug design has been used to manufacture a therapeutic peptide against ADAM22. A combination of in vitro, in vivo and patient studies has confirmed a role for ADAM22 in metastatic breast cancer. Our novel peptide mimetic may form a future basis for targeting ADAM22 in endocrine resistant disease.
Title: Reversal of endocrine therapy resistance with inhibitors of AKT, mTOR, or MEK as single agents or in combination

Agostina Nardone¹, Gladys Morrison¹, Xiaoyong Fu¹, Martin Shea¹, Tamika Mitchell¹, Teresa Klinowska³, C Kent Osborne¹,² and Rachel Schiff¹,². ¹Lester and Sue Smith Breast Center, Baylor College of Medicine, Houston, TX; ²Dan L. Duncan Cancer Center, Baylor College of Medicine, Houston, TX and ³AstraZeneca iMED, Macclesfield, United Kingdom.

Body: Background: Crosstalk between estrogen receptor (ER) and growth factor receptor (GFR) downstream signaling pathways [PI3K/AKT/mTOR and MEK\p42\44MAPK (MAPK)] has been associated with endocrine resistance. Single downstream inhibitors like everolimus partially reverse endocrine resistance. However, more than one downstream escape pathway may contribute to endocrine resistance. Furthermore, disruption by a single downstream inhibitor of the negative feedback loops that balance the amplified signals from GFRs may result in compensatory pathway activation. Therefore we investigated whether dual downstream signaling inhibitions are required to more effectively overcome tamoxifen-resistant growth, using in vitro and in vivo models.

Materials and Methods: The effects of different kinase inhibitors (i) AZD2014 (mTORi), AZD5363 (AKTi), and AZD6244 (MEKi) on endocrine therapy [tamoxifen (Tam) and fulvestrant (Fulv)] were tested in ER+ MCF7 and T47D Tam-resistant derivatives (TamR). In vitro growth and apoptosis were assessed using methylene blue and c-PARP, respectively. Western blot analysis was used to analyze the effect of each inhibitor or combination on their respective pathway substrates. Nude mice with transplantable MCF7 TamR xenografts at a size of 200 mm3 were randomized to continued Tam, continued Tam + (mTORi, AKTi, MEKi, mTORi+MEKi, AKTi+MEKi) or Fulv ± the inhibitor combinations.

Results: We found that in two ER+ models MCF7 TamR and T47D TamR in vitro, both mTORi and AKTi were effective in restoring growth inhibition, and effective in inhibiting their respective pathways. Interestingly, inhibition of mTOR and AKT resulted in upregulation of pMAPK. However, while MEKi did inhibit its pathway; it did not restore growth inhibition by the antiestrogens. On the other hand, dual inhibition, adding the MEKi to either mTORi or AKTi, resulted in a more potent reduction of cell growth as well as of downstream signaling. In the TamR derivative of MCF7, ER is still maintained and plays a role in resistance, unlike the T47D model, where there is little to no ER expression after TamR develops. Thus, as might be expected, combining downstream inhibitors with potent ER blockade by Fulv enhances the effect of single and dual downstream signaling inhibitors mainly in the MCF7 TamR model. Finally, Fulv in addition to dual downstream inhibitions (mTORi+MEKi or AKTi+MEKi) delayed MCF7 TamR xenograft growth significantly more than Fulv with single downstream inhibitors.

Conclusion: This study provides evidence that dual inhibition of GFR downstream pathways is needed to overcome activation of escape mechanisms that are up-regulated with acquired endocrine resistance and after resistance to single pathway inhibitors. Although the downstream inhibitors alone significantly inhibit TamR growth, combination with Fulv robustly slowed growth of TamR tumors in vivo. Based on these results further studies combining MEK inhibition with inhibitors of the PI3K pathway and ER downregulators are warranted.
Title: AKT antagonist AZD5363 targets estrogen receptor (ER) function in endocrine resistant breast cancer (BC) and synergises with fulvestrant in vivo

Lesley-Ann Martin1, Stephanie K Guest1, Sunil Pancholi1, Ricardo Ribas1, Qiong Gao1, Nikiana Simgidala1, Aradhana Rani1, Barry Davies2, Stephen Johnston3 and Mitch Dowsett3. 1Institute of Cancer Research, London, United Kingdom; 2AstraZeneca, Macclesfield, United Kingdom and 3Royal Marsden Hospital, London, United Kingdom.

Body: AIM: To evaluate the efficacy and functional consequences of combining AZD5363 with endocrine therapy in pre-clinical models of endocrine-sensitive and resistant ER+ BC.

BACKGROUND: The PI3K/AKT/mTOR signalling pathway plays an important role in BC. Its close interaction with ER signalling becomes more complex and inter-dependent with acquisition of endocrine resistance. Targeting the mTOR pathway in combination with endocrine therapy has shown clinical utility. However, a negative feedback loop exists downstream of the PI3K/AKT/mTOR pathway with mTOR inhibition leading to increased activation of IGFR1-dependent AKT activity potentially negating long-term benefit. Direct blockade of AKT in combination with endocrine therapy, may provide a better rationale for treatment of endocrine-resistant BC, impacting on both cell survival/apoptosis and ER ligand-independent signaling. In this investigation, we assessed the efficacy of AZD5363, a pan-AKT inhibitor with endocrine therapies in pre-clinical models of endocrine sensitive and resistant ER+ BC and its impact on molecular and cellular response.

METHODS: Inhibition of AKT using AZD5363 was examined in 5 ER+ BC lines before and after adaptation to long-term estrogen deprivation (LTED) or tamoxifen (TAMR). The effects of AZD5363 on cell proliferation were determined alone and in combination with endocrine treatment and feedback upregulation and activation of receptor tyrosine kinases (RTKs) was examined by western blotting. ER-transactivation was measured with an estrogen-response element (ERE)-linked luciferase reporter construct and confirmed using chromatin-immunoprecipitation. Global gene expression analysis was used to identify pathways associated with response. Xenografts were treated with AZD5363 ± fulvestrant to determine in vivo effects.

RESULTS: AZD5363 caused a dose-dependent decrease in proliferation in all cell lines tested (GI50<500nM) with the exception of HCC1428-wild-type and LTED. Of note both T47D-LTED and ZR75-LTED, which lose expression of ER were exquisitely sensitive (GI50∼100nM). AZD5363 re-sensitised the TAMR cell line to tamoxifen and acted synergistically with fulvestrant in MCF7-Wt and MCF7-LTED (CI<1). AZD5363 decreased phosphorylation of AKT/mTOR substrates PRAS40, p70S6 and S6 in all cell lines tested and caused a significant decrease in phosphorylation of ERα with an associated 50% reduction in ERα-mediated transcription and decrease in recruitment of ER and CBP to ERE on the TFF1 promoter. Furthermore, AZD5363 reduced Rb and cyclinD1. Inhibition of AKT with AZD5363 resulted in upregulation and activation of RTKs, including IGF-IR, EGFR, ERBB2 and ERBB3, which was cell line specific. Global gene expression and pathway analysis of MCF7 and MCF7-LTED treated with AZD5363 highlighted the relevance of ERBB2-ERBB3, ERK5 and IGF1 signalling as potential feedback loops. Combined treatment with AZD5363 and fulvestrant showed strong synergy in an MCF7 xenograft.

CONCLUSION: These data suggest that AZD5363 plus fulvestrant may be effective in BC that is sensitive or resistant to E-deprivation or tamoxifen and that activated AKT is a determinant of response. These data strongly support the need for clinical evaluation.
A nude mouse model of diet-induced-obesity to study the mechanisms of resistance to aromatase inhibitor letrozole in MCF-7Ca xenografts

Body: Obesity has been identified as one of the risk factors for breast cancer progression. However, the mechanisms underlying this link are not completely understood. Specifically, breast cancer patients who are overweight, obese or have excess abdominal fat have increased risk of local or distant (metastasis) recurrence and cancer related death. Furthermore, breast cancer patients gain weight during treatment, especially those who receive hormone depletion therapies, are at increased risk of developing obesity and metabolic syndrome as survivors. Importantly, the presence of obesity may influence the resistance of breast cancer to existing treatments, such as aromatase inhibitors (AIs). In an effort to understand the effect of obesity on the growth of hormone-dependent breast cancer tumors, we fed ovariectomized athymic nude mice a diet containing 45% kcal fat (45% of the total calories coming from the fat in the diet) and low fat (10% kcal fat) diet. We also used a standard chow diet to compare with our previous results. We saw that mice fed 45% kcal fat diet had a higher rate of tumor growth (p=0.04) compared to mice that were fed 10% kcal fat containing diet or chow diet. In addition, the mice fed 45% kcal fat had higher body weight, fasting insulin (as measured by C-peptide ELISA) and high fasting glucose levels. Glucose tolerance test (IP-GTT) demonstrated that mice fed high fat diet exhibited reduced glucose tolerance as measured by high AUC_{glucose} in high fat versus low fat or chow diet. There was no statistically significant difference between the chow diet and the low fat diet.

Next, we examined the effect of insulin on the growth of MCF-7Ca cells in response to E₂ or letrozole. When co-treated with 2µM of exogenous insulin (in otherwise serum starved condition), the growth of MCF-7Ca cells was not stimulated by E₂ at 1nM. However, at lower doses, the combination of insulin with E₂ stimulated cell growth more than E₂ alone. This suggests that insulin makes MCF-7Ca breast cancer cells hypersensitive to mitogenic effects of E₂. Hypersensitivity to E₂ is one of the suggested mechanisms of resistance to endocrine therapy. Furthermore, response to anti-proliferative effects of letrozole was also abrogated in presence of insulin (2µM). This was more pronounced at lower dose of letrozole. These results suggest that the presence of insulin makes MCF-7Ca cells less responsive to E₂ and letrozole. Furthermore, tumors of mice fed with high-fat diet also had higher activation of MAPK and Akt, suggesting induction of growth factor receptor pathways. Exogenous insulin treatment of MCF-7Ca cells also resulted in reduction of ERα protein levels and increase in p-IR, p-IGFR and p-Akt. These results suggest that diet-induced obesity may result in acquisition of resistance to letrozole due to development of hyperinsulinemia. We hypothesized that the presence of obesity can augment adaptation of cancer cells and impact the mechanism. This may be the result of a dramatically different hormonal milieu upon development of obesity.

Body: The estrogen receptor alpha (ERα) is a member of the nuclear hormone receptor (NHR) family and is critical for the etiology and treatment of breast cancer. Approximately 70% of breast cancers express ERα and many of these are sensitive to anti-estrogen therapies. Selective estrogen receptor modulators (SERMs), such as tamoxifen and raloxifene, are approved to treat or reduce the risk of ER-dependent breast cancers. SERMs act by competitively binding to the ERα ligand-binding domain (LBD). Unfortunately, metastatic breast tumors recur in approximately half of patients and become SERM resistant while remaining ER-positive in many cases. Recently, conserved somatic mutations in the ERα LBD were identified in patients who received SERM/aromatase inhibitor (AI)/selective estrogen receptor disruptor (SERD) therapy for an average of five years. Because these mutations were observed in approximately 25% of tumors and the most frequent mutations (Y537S or D538G) were located in or just prior to helix 12 (H12), the molecular switch that controls AF-2 activity, they represent a possible mechanism for acquired SERM insensitivity for a significant population of patients. Further studies revealed that these mutations conferred hormone-independent ERα activity and that the inhibitory efficacy of currently approved SERMs was reduced. Our goal is to understand the effects of these mutations on the structure and function of ERα in these tumors to guide the generation of novel compounds which bypass the effects of these somatic mutations. Here, we employ x-ray crystallography, molecular dynamics simulations, biochemical assays in addition to breast cancer cell proliferation assays to dissect the role of somatic mutation in acquired hormone/SERM resistance. X-ray crystal structures of the ERα LBD D538G mutant in the unliganded (apo), agonist and SERM-bound states, combined with molecular dynamics simulations, reveal a stabilized loop between H11 and H12 that allows the receptor to preferentially adopt an agonist conformation versus an antagonist conformation. The biochemical and breast cancer cell proliferation assays reveal structural insights that may explain mutant ERα function within the tumor. Further, we use these methods to explore the utility of next generation SERMs and SERDs to inhibit these mutant ERs as well as to guide the synthesis of additional novel compounds. Importantly, our work is expected to yield more potent and effective SERMs/SERDs that overcome the impact of acquired activating mutations and result in improved patient survival.
Title: Effect of a novel selective progesterone receptor modulator EC312 for menopausal hormone therapy (MHT) in comparison with Bazedoxifene in vitro

Body: Significant increase in the breast cancer risk reported from the Women’s health initiative (WHI) study and other clinical studies in postmenopausal women lead to a significantly reduced usage of estrogen/ progestin based HRT treatment in women. A new and interesting approach to provide women with an effective treatment for vasomotor symptoms without an increased breast cancer risk has been reported in preclinical and clinical studies. A combination of conjugated estrogens (CE) + selective estrogen receptor modulator (SERM), bazedoxifene (BZA) offers an effective treatment for overcoming vasomotor symptoms but preventing the proliferation of breast tissue. However, this treatment also has some drawbacks. A higher rate of induced endometrial hyperplasia due to unopposed estrogenicity with BZA+ CE treatment regimen has been noted in recent randomized clinical trials. In addition, the risk of venous thromboembolic events has been shown not avoided completely in women who were older at the time of BZE+CE treatment compared with those who were younger. Therefore an unmet need for new HRT regiments that combine effective treatment of symptoms without increasing the risk of breast cancer in postmenopausal women.

A potential approach is the combination of estradiol with a partial agonistic antiproprgestin (mesoprogstin or SPRM). In order to test the hypothesis we have compared the combinatory effect of BZA with estrogen (E2) as well as a novel SPRM, EC312+ E2 in a cell culture model of postmenopausal breast cancer. In our model, we have found that the antiestrogenic effect of BZA on T47D cell growth was comparable that of EC312. Both EC312 and BZA increased apoptosis dose dependently in the presence of E2 as well as reduced E2 mediated BrdU incorporation as a read out of cell proliferation. E2 (1nM) treatment increased the expression of anti-apoptotic genes whereas 100nM treatment of EC312 and BZA decreased the levels of anti-apoptotic genes. Expression of E2 stimulated effect on target genes such as cMyc, pS2 and Cyclin D1 were reduced with the treatment of EC312 or BZA. It is evident from our study that EC312 as a novel SPRM exerted no agonistic effects on human breast cancer cells and effectively blocked the stimulatory actions of E2 or conjugated estrogens. The in vitro molecular characterization of EC312 was performed using gene transactivation assays and confirmation of EC312 as a PRM was determined in cycling guinea pig model. Our future animal model with breast cancer xenografts will underscore the possibility of using EC312 as a safer SPRM that antagonize the growth promotional effect of estrogens as well as eliminating the increased breast cancer risk of progestin component of MHT. Further rationale for choosing SPRM/mesoprogestin such as EC312 would stabilize the uterine tissue and endometrium to minimize the oligo-menorrhea and endometrial hyperplasia associated with MHT.
Title: Glucocorticoid and aldosterone mimic progestin-induction of a therapy-resistant cytokeratin-5 positive cell population in estrogen receptor-positive breast cancer through a Bcl6-dependent mechanism
